

Supplementary material for the paper

Gábor Oszlányi and András Sütő:
“A charge flipping algorithm to handle incomplete data”

This document contains the data of structure solution efficiency for the 8 test structures discussed in the paper.

Data for separate structures are shown on separate pages.

Each page contains four tables, two for missing high-resolution data and two for missing low-resolution data.

Within each resolution block, the first table was obtained by using the iteration scheme AAR,
and the second one (for comparison) by using the simplest Fourier recycling scheme.

The first row of all tables is the respective resolution limit in Å units.

This is $d_2=1/h_2$ for missing high-resolution data, and $d_1=1/h_1$ for missing low-resolution data.

The first column of all tables is the k parameter of the dynamic charge flipping threshold $\delta = k \sigma$.

At each resolution and each threshold two indicators are given: the average number of iteration cycles needed
for a structure solution, and the number of solutions obtained. Details of the protocol are described in the paper.
Bold typeface marks the threshold ranges used for obtaining the double-averaged tables presented in the paper.
