# The Perchlorophenalenyl Radical, $\mathrm{C}_{13} \mathrm{Cl}_{9}$ : A Modulated Structure with Nine Threefold-Symmetric Molecules in the Asymmetric Unit 

By P. A. Koutentis, ${ }^{\text {a }}$ R. C. Haddon,,${ }^{\text {a }}$ R. T. OAKley, ${ }^{\text {b }}$ A. W Cordes ${ }^{\text {c }}$ \& C. P. Brock ${ }^{\text {a }}$<br>${ }^{\text {a }}$ Departments of Chemistry and Physics and the Center for Advanced Carbon Materials, University of Kentucky, Lexington, KY 40506-0055, USA,<br>${ }^{b}$ Department of Chemistry, University of Waterloo, Waterloo, Ontario N2L 3G1, Canada, and ${ }^{c}$ Department of Chemistry and Biochemistry, University of Arkansas, Fayetteville, AR 72701, USA

Synopsis: The strongly ruffled, odd-alternant radical $\mathrm{C}_{13} \mathrm{Cl}_{9}$ stacks along crystallographic threefold axes, but the intrastack spacing is too large for the material to be a good conductor. The spacing is determined by interstack interactions, which are also responsible for the structural modulations.

Contents: Precession projections for the first and second crystals showing layers hk5, hk6, and hk7 (2 pages).

Wilson plots (1) for reflections having different values of $\bmod (1,6)$, and (2) for reflections having $\bmod (1,6)=0$ and different values of $\bmod (-\mathrm{h}+\mathrm{k}-1,3)(2$ pages)

SHELXL97input/output file from the final least squares cycle.

Tables of crystallographic information generated in Chester.

Description of the quantum-mechanical calculations (5 pages).

Precession projections hkn, $n=0,1,2$, and 3 for a crystal of the "other" phase (2 pages)

## Electronic and Molecular Structure of $\mathrm{C}_{13} \mathbf{H}_{9}(\mathrm{PLY})$ and $\mathrm{C}_{13} \mathrm{Cl}_{9}$ (PCPLY)

We have carried out $a b$ initio density functional theory calculations, at the B3LYP/6$31 G^{* *}$ level, on PCPLY $\left(\mathrm{C}_{13} \mathrm{Cl}_{9}\right)$ and its parent radical, PLY $\left(\mathrm{C}_{13} \mathrm{H}_{9}\right)$. Geometry optimizations were performed within $\mathrm{D}_{3 \mathrm{~h}}$ symmetry constraints on PLY, its cation and anion; frequency calculations confirmed that these were true minima. In the case of PCPLY, where the X-ray results clearly signal a puckering of the molecule away from $\mathrm{D}_{3 \mathrm{~h}}$, geometry optimizations on all three oxidation states were performed in $D_{3}$ as well as in $D_{3 h}$ symmetry (Table 1).

Delta $=$ the difference in bond distances between the cation and anion

Total energies and energy differences, as a function of oxidation state, are shown in Table
2. While the distortion of PCPLY away from $D_{3 h}$, measured in terms of the pitch angle $\tau$, is relatively constant (near $8^{\circ}$ ) for all oxidation states, the stabilization energy occasioned by puckering changes with the charge on the ring. The anion is most stabilized by the distortion,
while the cation is least stabilized. These trends can be attributed to the introduction of s-orbital character into the $\pi$-system as the distortion progresses - it is the curved carbon effect. ${ }^{1}$ As a result, both the IP and EA of PCPLY increase with ring puckering. Insofar as the changes are approximately the same, the overall value of the disproportionation energy (IP-EA) remains relatively constant.

Table 2. Computed total energies (Hartrees), IP, EA and $\Delta \mathrm{H}_{\text {disp }}$ values (eV) for PLY and PCPLY.

The computed ionization potential (IP) and electron affinity (EA) values parallel the results of the electrochemical measurements on PLY and PCPLY; the latter is harder to oxidize, and much easier to reduce. ${ }^{2,3}$. Indeed the gas phase data for PCPLY rank it as a pseudo halogen. This conclusion is not surprising given the combined inductive and conjugative influence of nine chlorines on the PCPLY periphery. However, the change in IP-EA is much larger than the corresponding change in the $E_{\text {cell }}$ value. Indeed a shift in IP-EA of near 1 eV would, on the basis of our experience with CSN radicals, should lead to a more substantial decrease in $\mathrm{E}_{\text {cell }}$ between PLY and PCPLY.

## Spin Densities and ESR Hyperfine Coupling Constants

PLY is an odd-alternant hydrocarbon; at the HMO level its non-bonding SOMO is nodal at all but the C01 positions. The computed spin densities for PLY (Table 2) and PCPLY (Table 3) at the B3LYP/6-31G** level) mirror these basic one-electron ideas, although both the C 02 and C 04 carbons are associated with a substantial negative spin density. The calculated hyperfine coupling constants for PLY are in reasonable agreement with the experimental values. ${ }^{4}$

In the case of PCPLY there is very little spin leakage to the exocyclic chlorines, and the of loss in ring planarity (from $D_{3 h}$ to $D_{3}$ ) are minimal; the changes in spin densities accompanying ring puckering are small. Interestingly, spin leakage to chlorine decreases with puckering. Computed coupling constants are also provided in Table 2; the calculated $\mathrm{a}_{\mathrm{Cl}}$ values are small, regardless of geometry $\left(D_{3 h}\right.$ or $\left.D_{3}\right)$.

## Experimental Section

ab Initio Calculations All calculations were run on Pentium workstations using the B3LYP DFT method and a 6-31G** basis set, as contained in the Gaussian 98W suite of programs. ${ }^{1}$ The geometries of the PLY anion, radical and cation were fully optimized in $\mathrm{D}_{3 \mathrm{~h}}$ symmetry; frequency calculations confirmed that the geometries were true minima. Optimization of the PCPLY anion, radical and cation were performed within both $\mathrm{D}_{3 \mathrm{~h}}$ and $\mathrm{D}_{3}$ symmetry constraints. The puckering of the PCPLY framework away from $D_{3 h}$ symmetry is defined in terms of the pitch angle of the blades of the PCPLY propeller.
