Introduction

The tables presented here were assembled for combinations of a Si- or Diamond high-heat-load monochromator followed by one or two pairs of high-resolution Si channel-cut crystals, as indicated under [Monochromator Geometry]. The rationale for this crystal arrangement is inspired by the fact that the angular acceptance of the high-resolution portion is proportional to $1/\sin(2\Theta_B)$. This term becomes large for near-backscattering conditions and thus guarantees an optimal throughput, while many choices of reflections arise to closely match the band pass to the analyzer resolution. The band pass and throughput data were calculated by multiplying a Gaussian x-ray source distribution with all pertinent dynamical crystal reflectivities as shown under [Tables] and numerically integrating over angle and energy.

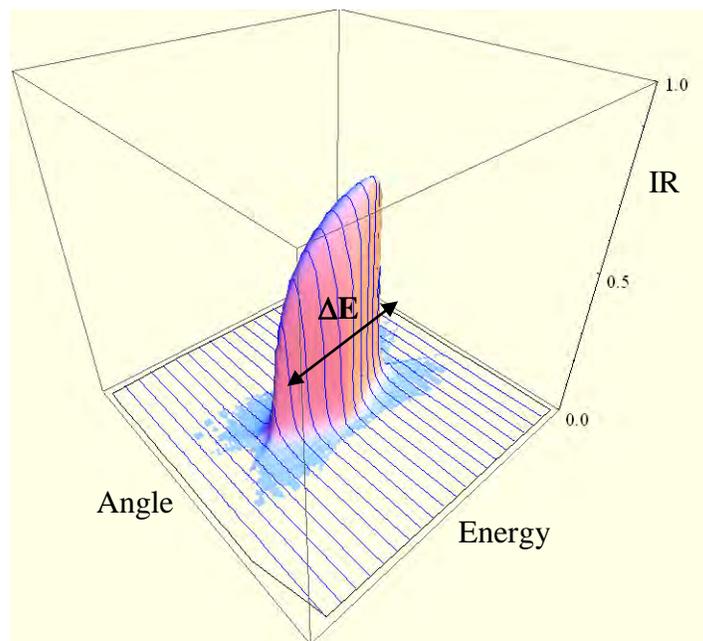

The monochromator tables involve source parameters specific to the APS. Nevertheless, they still provide useful guidance generally in as much as source characteristics of 3rd generation synchrotron sources are rather similar.

Tables

The bandpass- and throughput data in the monochromator tables were compiled by superposing a Gaussian source distribution (see below) and all pertinent dynamical crystal reflectivities. The resulting intensity profile is then numerically integrated over angle and energy.

Source distribution and crystal reflectivities as functions of angle and energy

Intensity profile as a function of angle and energy, resulting from superposition of source distribution and crystal reflectivities

Source Parameters

Monochromator tables are based on a typical vertical source distribution for an undulator beamline at the Advanced Photon Source of Argonne Nat'l Laboratory.

Pertinent parameters are

Undulator Length:

$$L_u = 4.8m$$

Electron beam divergence, vertical:

$$\sigma'_y = 3.3\mu rad$$

Photon beam divergence, vertical, incident energy E_i :

$$\sigma'_r = \sqrt{hc / E_i L_u}$$

Combined beam divergence, vertical:

$$\Sigma'_y = \sqrt{\sigma_y'^2 + \sigma_r'^2}$$

Gaussian angular source distribution:

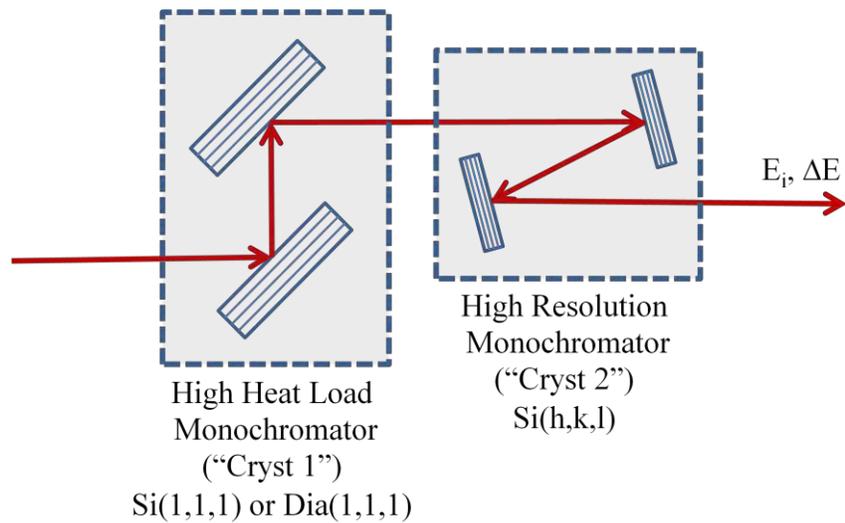

$$G(\theta) = e^{-\theta^2 / 2\Sigma_y'^2}$$

Monochromator Geometry

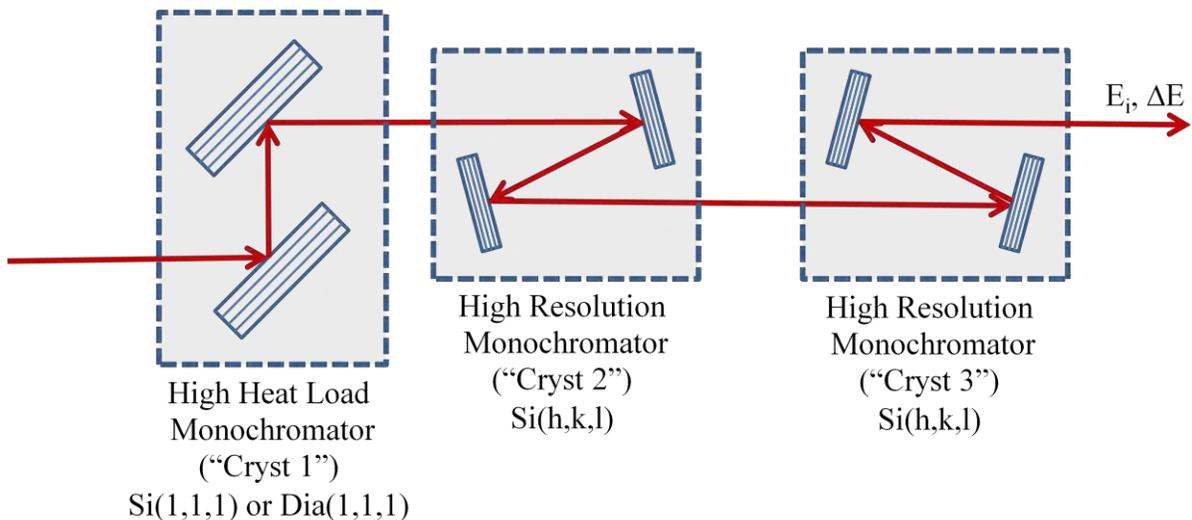

Monochromator assemblies consisting of two combinations of channel-cut crystals are considered:

1. One pair of Si(1,1,1) or Diamond(1,1,1) crystals followed by one pair of Si(h,k,l) crystals in dispersive configuration
2. One pair of Si(1,1,1) or Diamond(1,1,1) crystals followed by two pairs of Si(h,k,l) in dispersive configuration

Crystals can be realized as monolithic or virtual channel-cuts.

Monochromator assembly consisting of two pairs of crystals

Monochromator assembly consisting of three pairs of crystals

Quantities Listed in the Tables

Cryst 1

Type of first crystal pair, corresponding to the high-heat-load portion of the monochromator assembly. Types considered are Si(1,1,1) and Diamond(1,1,1)

Cryst 2, 3

Type of second and third crystal pair, corresponding to the high-resolution portion of the monochromator assembly.

BraggAngle Θ_B 2

Bragg angle of the second and third pair of crystals

Bandpass ΔE

Energy bandpass of the monochromator assembly, as determined by numerically integrating the superposition of source distribution and dynamical reflectivities in angle, yielding an overall energy profile.

Integrated Reflectivity, $\int I_R d\Theta dE$

As a measure of photon throughput the superposition of source distribution and dynamical reflectivities is numerically integrated over angle and energy.

FOM

Figure-of-merit defined as ratio of Integrated Reflectivity / Bandpass
