## Derivation considering Lognormal distribution:

Let the scattering intensity be I(q). In fact, from the standard definition of the intensity,

$$
I(q)=(\Delta \rho)^{2} \frac{\int_{0}^{\infty} P(q) D(r) V^{2}(r) d r}{\int_{0}^{\infty} D(r) V(r) d r}=(\Delta \rho)^{2} \frac{\int_{0}^{\infty} \frac{9(\sin (q r)-q r \cos (q r))^{2}}{(q r)^{6}} D(r) V^{2}(r) d r}{\int_{0}^{\infty} D(r) V(r) d r}
$$

Thus, $I(q)=(\Delta \rho)^{2}(12 \pi) \frac{\int \frac{(\sin (q r)-q r \cos (q r))^{2}}{\left(q^{6} r^{6}\right)} D(r) r^{6} d r}{\int D(r) r^{3} d r}$

The denominator of the above equation is a q independent term.
Thus, I(q) is proportional to $\int \frac{(\sin (q r)-q r \cos (q r))^{2}}{\left(q^{6}\right)} D(r) d r$
So, $I(q) \propto \int \frac{(\sin (q r)-q r \cos (q r))^{2}}{\left(q^{6}\right)} D(r) d r$
The integration in the above equation is on $r$ and hence by rearranging $q^{4}$ term,

$$
\begin{equation*}
I(q) q^{4} \propto \int \frac{(\sin (q r)-q r \cos (q r))^{2}}{\left(q^{2}\right)} D(r) d r \tag{1}
\end{equation*}
$$

At the peak ( $q=q_{\text {peak }}$ ) in the Porod plot

$$
\begin{equation*}
\frac{\partial}{\partial q}\left(I(q) q^{4}\right) \sim \frac{\partial}{\partial q}\left(\int \frac{(\sin (q r)-q r \cos (q r))^{2}}{\left(q^{2}\right)} D(r) d r\right)=0 \tag{2}
\end{equation*}
$$

$$
\left(\int_{0}^{\infty} \frac{q^{2}\left(2(\sin (q r)-q r \cos (q r))\left(r \cos (q r)+q r^{2} \sin (q r)-r \cos (q r)\right)\right)-2 q(\sin (q r)-q r \cos (q r))^{2}}{q^{4}} D(r) d r\right)=0
$$

$$
\left(\int_{0}^{\infty}\left(\frac{q^{3} r^{2} \sin (q r)(\sin (q r)-q r \cos (q r))-q(\sin (q r)-q r \cos (q r))^{2}}{q^{4}}\right) D(r) d r\right)=0
$$

$$
\left(\int_{0}^{\infty} q^{2} r^{2} \sin (q r)(\sin (q r)-q r \cos (q r))-(\sin (q r)-q r \cos (q r))^{2} D(r) d r\right)=0
$$

$$
\text { for } q=q_{p e a k}
$$

For a lognormal distribution

$$
D(r)=\left(\frac{1}{\sqrt{2 \pi} \sigma r}\right) \exp \left(-\frac{\left(\ln \left(r / R_{m}\right)\right)^{2}}{2 \sigma^{2}}\right) d r
$$

Let us consider $\mathrm{r} / \mathrm{R}_{\mathrm{m}}=\mathrm{x}$

$$
\left(\int_{0}^{\infty}\left(q_{p} R_{m} x\right)^{2} \sin \left(q_{p} R_{m} x\right)\left(\sin \left(q_{p} R_{m} x\right)-q_{p} R_{m} x \cos \left(q_{p} R_{m} x\right)\right)-\left(\sin \left(q_{p} R_{m} x\right)-q_{p} R_{m} x \cos \left(q_{p} R_{m} x\right)\right)^{2} R_{m} D(x) d x\right)=0
$$

Let us put $q_{\text {peak }} * R_{m}=K$
$\left(\int_{0}^{\infty} K^{2} x^{2} \sin (K x)(\sin (K x)-K x \cos (K x))-(\sin (K x)-K x \cos (K x))^{2} R_{m}\left(\frac{1}{\sqrt{2 \pi} x R_{m}}\right) \exp \left(-\frac{(\ln (x))^{2}}{2 \sigma^{2}}\right) d x\right)=0$

The integration is over $\mathbf{x}$ as dummy variable, so the resulting integral will depend on $K$ and $\sigma$ only.

Thus, the above Function $(K, \sigma)=0$, so $K$ is a function of $\sigma$ only and does not depend on $\mathrm{R}_{\mathrm{m}}$. So, $K=K(\sigma)$
 independent of $\boldsymbol{R}_{m}$ )

Thus, $q_{\text {peak }} * R_{m}=K(\sigma)$, i.e., $q_{\text {peak }} * R_{m}$ and depends on $\sigma$ only,

Now,

$$
\int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2} q^{4} \int_{0}^{\infty} \frac{(\sin (q r)-q r \cos (q r))^{2}}{(q r)^{6}} D(r) r^{6} d r
$$

$$
\begin{align*}
& \int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2} q^{4} \int_{0}^{\infty} \frac{(\sin (q r)-q r \cos (q r))^{2}}{(q)^{6}} D(r) d r \\
& \int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2}\left(K / R_{m}\right)^{4} \int_{0}^{\infty} \frac{(\sin (x K)-x \cos (x K))^{2}}{\left(K / R_{m}\right)^{6}} D\left(x R_{m}\right) R_{m} d x \\
& \int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2} \int_{0}^{\infty} \frac{(\sin (x K)-x \cos (x K))^{2}}{\left(K / R_{m}\right)^{2}}\left(\frac{1}{\sqrt{2 \pi} x R_{m}}\right) \exp \left(-\frac{(\ln (x))^{2}}{2 \sigma^{2}}\right) R_{m} d x \\
& \int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2}\left(R_{m}\right)^{2} \int_{0}^{\infty} \frac{(\sin (x K)-x \cos (x K))^{2}}{K^{2}}\left(\frac{1}{\sqrt{2 \pi} x}\right) \exp \left(-\frac{(\ln (x))^{2}}{2 \sigma^{2}}\right) d x \\
& \text { Let us assume } f(\sigma)=(12 \pi) \int_{0}^{\infty} \frac{(\sin (x K)-x \cos (x K))^{2}}{K^{2}}\left(\frac{1}{\sqrt{2 \pi} x}\right) \exp \left(-\frac{(\ln (x))^{2}}{2 \sigma^{2}}\right) d x \quad \ldots . . . . . . . .(3) \tag{3}
\end{align*}
$$

So $\int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(\Delta \rho)^{2}\left(R_{m}\right)^{2} f(\sigma)$ Thus, $\left(I(q) q^{4}\right)=(\Delta \rho)^{2}\left(R_{m}\right)^{2} f(\sigma) /\left(\int_{0}^{\infty} D(r) r^{3} d r\right)$ Now $\int_{0}^{\infty} D(r) r^{3} d r=R_{m}{ }^{3} \exp \left(9 \sigma^{2} / 2\right)$ So, $\left(I\left(q_{\text {peak }}\right) q_{\text {peak }}{ }^{4}\right)=\left(1 / R_{m}\right) f(\sigma) /\left(\exp \left(9 \sigma^{2} / 2\right)\right)$ Now $\Sigma_{P}=I\left(q_{\text {Porod }}\right) q_{\text {Porod }}{ }^{4}=(2 \pi)(\Delta \rho)^{2} \frac{S}{V}=(2 \pi)(\Delta \rho)^{2} c \frac{\left\langle r^{2}\right\rangle}{\left\langle r^{3}\right\rangle}=(2 \pi)(\Delta \rho)^{2} c \frac{R_{m}{ }^{2} \exp \left(4 \sigma^{2} / 2\right)}{R_{m}{ }^{3} \exp \left(9 \sigma^{2} / 2\right)}$
$I\left(q_{\text {Porod }}\right) q_{\text {Porod }}{ }^{4}=(2 \pi)(\Delta \rho)^{2} c \frac{R_{m}{ }^{2} \exp \left(4 \sigma^{2} / 2\right)}{R_{m}{ }^{3} \exp \left(9 \sigma^{2} / 2\right)}=(2 \pi)(\Delta \rho)^{2} c \frac{\exp \left(-2.5 \sigma^{2}\right)}{R_{m}}$
So, $\frac{I\left(q_{\text {Peak }}\right) q_{\text {Paak }}{ }^{4}}{I\left(q_{\text {Porod }}\right) q_{\text {Porod }}{ }^{4}}=\left(\left(R_{m}{ }^{-1}\right) f(\sigma) /\left(\exp \left(9 \sigma^{2} / 2\right)\right)\right)\left((2 \pi) c \frac{\exp \left(-2.5 \sigma^{2}\right)}{R_{m}}\right)^{-1}$
$\frac{I\left(q_{\text {Peak }}\right) q_{\text {Peak }}{ }^{4}}{I\left(q_{\text {Porod }}\right) q_{\text {Porod }}}=\left(f(\sigma) \times\left(\exp \left(9 \sigma^{2} / 2\right)\right)^{-1}\right)\left((2 \pi) c \exp \left(-2.5 \sigma^{2}\right)\right)^{-1}$

$$
\begin{equation*}
\frac{I\left(q_{\text {Peak }}\right) q_{\text {Peak }}{ }^{4}}{I\left(q_{\text {Porod }}\right) q_{\text {Porod }}}=\frac{I\left(q_{\text {Peak }}\right) q_{\text {Peak }}{ }^{4}}{\Sigma_{P}}=(c 2 \pi)^{-1} f(\sigma)\left(\exp \left(-2 \sigma^{2}\right)\right) \tag{4}
\end{equation*}
$$

This shows that the ratio is independent of $R_{m}$ and depends on $\sigma$ only.

Let us try to approximate how the quantity $\mathrm{q}_{\text {peak }} * \mathbf{R}_{\mathrm{m}}$ behaves:
$I(q) q^{4} \propto(12 \pi) \int(\Delta \rho)^{2} \frac{(\sin (q r)-q r \cos (q r))^{2}}{\left(q^{2}\right)} D(r) d r$

First we will see the behavior with a Guinier approximation,

$$
I(q) q^{4} \propto q^{4} \exp \left(-\mathrm{q}^{2} \frac{1}{3} \mathrm{rg}^{2}\right)
$$

$$
\frac{\partial}{\partial q}\left(I(q) q^{4}\right) \propto 4 q^{3} \exp \left(-\mathrm{q}^{2} \frac{1}{3} \mathrm{rg}^{2}\right)-2 \mathrm{q}^{5} \frac{1}{3} \mathrm{rg}^{2} \exp \left(-\mathrm{q}^{2} \frac{1}{3} \mathrm{rg}^{2}\right)
$$

At the maximum

$$
2 q^{3}-\mathrm{q}^{5} \frac{1}{3} \mathrm{rg}^{2}=0 \text {, i.e } \mathrm{q}^{2} \mathrm{rg}^{2}=6 \quad \text { Now } \mathrm{rg}^{2}=\frac{3}{5} \frac{\left\langle r^{8}\right\rangle}{\left\langle r^{6}\right\rangle}
$$

Now for Lognormal distribution, $\mathrm{n}^{\text {th }}$ moment is given by

$$
\left\langle r^{n}\right\rangle=R_{m}^{n} \exp \left(n^{2} \sigma^{2} / 2\right)
$$

$$
\begin{equation*}
\mathrm{q}_{\text {peak }}^{2} R_{m}^{2} \propto C \exp \left(-D \sigma^{2}\right) \tag{5}
\end{equation*}
$$

However, this is based on the approximation that the maximum occur at small enough $q$ value, which is not exactly true.

Thus, we assume a more general form that fits the variation of $q_{\text {peak }}{ }^{2} R_{m}{ }^{2}$ and we try to estimate these unknown coefficients from the fit of the variation of this quantity with $\sigma$.

$$
\begin{equation*}
K(\sigma)^{2}=q_{P e a k}^{2} R_{m}^{2}=C_{1}+C_{2} \exp \left(-D_{2} \sigma^{2}\right)+C_{3} \exp \left(-D_{3} \sigma^{2}\right)+\ldots \ldots \tag{6}
\end{equation*}
$$

where $C_{1}, C_{2}, \ldots . . . . D_{2}, \ldots$. are some constants that needs to be determined.
It is already shown that

$$
\frac{I\left(q_{\text {Peak }}\right) q_{\text {Peak }}^{4}}{I\left(q_{\text {Porod }}\right) q_{\text {Porod }}{ }^{4}}=(c 2 \pi)^{-1} f(\sigma)\left(\exp \left(-2 \sigma^{2}\right)\right)
$$

where
$f(\sigma)=(4 \pi / 3)^{3} \int_{0}^{\infty} \frac{(\sin (x K)-x \cos (x K))^{2}}{K^{2}}\left(\frac{1}{\sqrt{2 \pi} x}\right) \exp \left(-\frac{(\ln (x))^{2}}{2 \sigma^{2}}\right) d x$
Please note that equation $\mathbf{7}$ is also similar to equation $\mathbf{2}$ but here $q$ gets replaced by $K$. It should be also noted that $q_{\text {peak }} R_{m}=K(\sigma)$. This means that with $R_{m}=1$, one can approximate the functional form of $f(\sigma)$ as of $K$.

Thus, the ratio T can also be represented in the similar form .

Thus, in summary,

$$
\begin{equation*}
T=\frac{I\left(q_{\text {Peak }}\right) q_{\text {Peak }}{ }^{4}}{\Sigma_{P}} \approx F_{1}+F_{2} \exp \left(-G_{2} \sigma^{2}\right)+F_{3} \exp \left(-G_{3} \sigma^{2}\right)+\ldots \ldots \tag{8}
\end{equation*}
$$

$$
\begin{equation*}
q_{\text {Peak }}^{2} R_{m}^{2}=K(\sigma)^{2}=C_{1}+C_{2} \exp \left(-D_{2} \sigma^{2}\right)+C_{3} \exp \left(-D_{3} \sigma^{2}\right)+\ldots \ldots \tag{9}
\end{equation*}
$$

The values of the quantities $F_{1}, F_{2}, F_{3}, G_{2}, G_{3}$ and $C_{1}, C_{2}, C_{3}, D_{2}$ and $D_{3}$ have been determined from the fitting from the fitting of the variation of $T$ and $\mathrm{q}_{\text {peak }}{ }^{2} \mathrm{R}_{\mathrm{m}}{ }^{2}$ with $\sigma$, as obtained from the simulation.

## Derivation considering Weibull distribution:

For a Weibull distribution

$$
\begin{equation*}
\mathrm{D}_{\mathrm{WB}}(\mathrm{r})=\left(\frac{\kappa}{\lambda}\right)\left(\frac{\mathrm{r}}{\lambda}\right)^{(\mathrm{k}-1)} \exp \left[-\left(\frac{\mathrm{r}}{\lambda}\right)^{\mathrm{k}}\right] \tag{10}
\end{equation*}
$$

Let us consider $r / R_{m}=x$ and let $\lambda=R_{m}$
$\left(\int_{0}^{\infty}\left(q_{p} R_{m} x\right)^{2} \sin \left(q_{p} R_{m} x\right)\left(\sin \left(q_{p} R_{m} x\right)-q_{p} R_{m} x \cos \left(q_{p} R_{m} x\right)\right)-\left(\sin \left(q_{p} R_{m} x\right)-q_{p} R_{m} x \cos \left(q_{p} R_{m} x\right)\right)^{2} R_{m} D(x) d x\right)=0$

Let us put $\mathrm{q}_{\mathrm{p}}{ }^{*} \mathrm{R}_{\mathrm{m}}=\mathrm{K}$
$\left(\int_{0}^{\infty} K^{2} x^{2} \sin (K x)(\sin (K x)-K x \cos (K x))-(\sin (K x)-K x \cos (K x))^{2} R_{m}\left(\frac{\kappa}{R_{m}}\right)(x)^{(k-1)} \exp \left[-(x)^{k}\right] d x\right)=0$

The integration is over $x$, so the resulting integral will depend on $K$ and $\sigma$ only.

Thus, the above Function $(K, \sigma)=0$, so $K$ is a function of $\sigma$ only and does not depend on $R m$.
So, $K=K(\sigma)$ (This should also be verified from simulation that the product $q_{p} R_{m}$ depends only on $\sigma$ and is independent of $R_{m}$ )

Thus, $q_{\text {peak }} * R_{m}=K(\sigma)$, i.e., $q_{\text {peak }} * R_{m}$ and depends on $\sigma$ only,

$$
\int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2} q^{4} \int_{0}^{\infty} \frac{(\sin (q r)-q r \cos (q r))^{2}}{(q r)^{6}} D(r) r^{6} d r
$$

$$
\begin{align*}
& \int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2} q^{4} \int_{0}^{\infty} \frac{(\sin (q r)-q r \cos (q r))^{2}}{(q)^{6}} D(r) d r \\
& \int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2}\left(K / R_{m}\right)^{4} \int_{0}^{\infty} \frac{(\sin (x K)-x \cos (x K))^{2}}{\left(K / R_{m}\right)^{6}} D\left(x R_{m}\right) R_{m} d x \\
& \int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2} \int_{0}^{\infty} \frac{(\sin (x K)-x \cos (x K))^{2}}{\left(K / R_{m}\right)^{2}}\left(\frac{\kappa}{R_{m}}\right)(x)^{(k-1)} \exp \left[-(x)^{k}\right] R_{m} d x \\
& \int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(12 \pi)(\Delta \rho)^{2}\left(R_{m}\right)^{2} \int_{0}^{\infty} \frac{(\sin (x K)-x \cos (x K))^{2}}{K^{2}}(\kappa)(x)^{(k-1)} \exp \left[-(x)^{k}\right] d x \\
& \text { Let us assume } f(\kappa)=(12 \pi) \int_{0}^{\infty} \frac{(\sin (x K)-x \cos (x K))^{2}}{K^{2}}(\kappa)(x)^{(k-1)} \exp \left[-(x)^{k}\right] d x \\
& \text { So } \int_{0}^{\infty} D(r) r^{3} d r \times\left(I(q) q^{4}\right)=(\Delta \rho)^{2}\left(R_{m}\right)^{2} f(\kappa) \text { Thus, }\left(I(q) q^{4}\right)=(\Delta \rho)^{2}\left(R_{m}\right)^{2} f(\kappa) /\left(\int_{0}^{\infty} D(r) r^{3} d r\right) \\
& \text { Now } \int_{0}^{\infty} D(r) r^{3} d r=R_{m}{ }^{3} \Gamma\left(1+\frac{3}{\kappa}\right) \text { So, }\left(I\left(q_{\text {peak }}\right) q_{\text {peak }}{ }^{4}\right)=\left(1 / R_{m}\right) f(\kappa) / \Gamma\left(1+\frac{3}{\kappa}\right) \\
& \text { Now } I\left(q_{\text {Porod }}\right) q_{\text {Porod }}{ }^{4}=(2 \pi)(\Delta \rho)^{2} \frac{S}{V}=(2 \pi)(\Delta \rho)^{2} c \frac{\left\langle r^{2}\right\rangle}{\left\langle r^{3}\right\rangle}=(2 \pi)(\Delta \rho)^{2} c \frac{R_{m}{ }^{2} \Gamma\left(1+\frac{2}{\kappa}\right)}{R_{m}{ }^{3} \Gamma\left(1+\frac{3}{\kappa}\right)} \\
& I\left(q_{\text {Porod }}\right) q_{\text {Porod }}{ }^{4}=(2 \pi)(\Delta \rho)^{2} c \frac{R_{m}{ }^{2} \Gamma\left(1+\frac{2}{\kappa}\right)}{R_{m}{ }^{3} \Gamma\left(1+\frac{3}{\kappa}\right)}=(2 \pi)(\Delta \rho)^{2} c \frac{\Gamma\left(1+\frac{2}{\kappa}\right)}{\Gamma\left(1+\frac{3}{\kappa}\right) R_{m}}  \tag{11}\\
& \text { So, } \frac{I\left(q_{\text {Peak }}\right) q_{\text {Peak }}{ }^{4}}{I\left(q_{\text {Porod }}\right) q_{\text {Porod }}{ }^{4}}=(2 \pi c)^{-1}\left(\frac{f(\kappa)}{\Gamma\left(1+\frac{2}{\kappa}\right)}\right)
\end{align*}
$$

$$
\begin{equation*}
\frac{I\left(q_{\text {Peak }}\right) q_{\text {Peak }}{ }^{4}}{I\left(q_{\text {Porod }}\right) q_{\text {Porod }}{ }^{4}}=(c 2 \pi)^{-1} f(\kappa)\left(\Gamma\left(1+\frac{2}{\kappa}\right)\right)^{-1} \tag{12}
\end{equation*}
$$

This shows that the ratio is independent of $\lambda$ and depends on $\kappa$ only.
Similar to the Lognormal case, here the two quantities can be represented in the form
$T=\alpha_{0}-\left(\alpha_{0}-\alpha_{1}\right) \exp \left(-\left(\alpha_{2} \kappa\right)^{\alpha_{3}}\right)$
$q_{\text {peak }} \lambda^{2}=\beta_{0}-\left(\beta_{0}-\beta_{1}\right) \exp \left(-\left(\beta_{2} \kappa\right)^{\beta_{3}}\right)$
The values of the quantities $\alpha_{0}, \alpha_{0}, \alpha_{1}, \alpha_{2}, \alpha_{3}$, and $\beta_{0}, \beta_{1}, \beta_{2}, \beta_{3}$, have been determined from the fitting of the variation of $T$ and $\mathrm{q}_{\text {peak }} \lambda^{2}$ with $\kappa$, as obtained from the simulation.
