## 1S. Hansen-Coppens formalism

In the Hansen-Coppens formalism (Hansen \& Coppens, 1978), the total atomic electron density (of the $k$-th atom) is the sum of three components:

$$
\varrho_{k}(\mathbf{r})=P_{\mathrm{ck}} \varrho_{\mathrm{ck}}(r)+P_{\mathrm{v} k} \kappa_{k}^{3} \varrho_{\mathrm{v} k}\left(\kappa_{k} r\right)+\sum_{l=0}^{l_{\max }} \sum_{m=-l}^{l} P_{l m k} \kappa_{l k}^{\prime 3} R_{l k}\left(\kappa_{l k}^{\prime} r\right) d_{l m k}(\theta, \varphi)
$$

where $\varrho_{c k}$ and $\varrho_{\mathrm{v} k}$ are the spherical 1-electron normalized core and valence densities, respectively. The third term contains the sum of the angular functions ( $d_{l m k}$ ) which model aspherical deformations. The angular functions $d_{l m k}$ consist of real spherical harmonic functions normalised to the electron density. The $P_{\mathrm{ck}}, P_{\mathrm{v} k}$ and $P_{l m k}$ coefficients stand for populations of the core, valence and deformation density multipoles, respectively. The radial functions ( $R_{l k}$ ) are defined as:

$$
R_{l k}(r)=\frac{\zeta_{l k}^{n_{l k}+3}}{\left(n_{l k}+2\right)!} r^{n_{l k}} \exp \left(-\zeta_{l k} r\right)
$$

where $\zeta_{l k}$ and $n_{l k}$ are parameters assigned to each element type separately. $\kappa$ and $\kappa^{\prime}$ are scaling parameters, which control the expansion and contraction of the valence spherical and deformation densities, respectively. For the purpose of this work, each atom was assigned with core and spherical-valence scattering factors derived from Su , Coppens \& Macchi wavefunctions (Macchi \& Coppens, 2001, Su \& Coppens, 1998). In the classical

Hansen-Coppens formalism, $P_{\mathrm{v} k}, P_{l m k}, \kappa$ and $\kappa^{\prime}$ constitute the refineable parameters together with the atomic coordinates and thermal motion coefficients.

## 2S. Structural refinement details

Refinements in the JANA program (Petříček et al., 2014) were done according to the transferred aspherical atom model (TAAM). Initial atomic coordinates $x, y$, and $z$, and anisotropic atomic displacement parameters ( $U_{i j}$ 's; anisotropic ADPs) for each atom were taken from the spherical refinement stage. Initial multipolar and contraction-expansion parameters were transferred from the University at Buffalo Data Bank (UBDB) (Dominiak et al., 2007, Jarzembska \& Dominiak, 2012) using the LSDB program (Jarzembska \& Dominiak, 2012, Volkov et al., 2004), which also assigns optimal local coordinate systems to each atom, scales fragment charges, and standardizes $\mathrm{X}-\mathrm{H}$ bond lengths ( $\mathrm{X}=$ nonhydrogen atom) to average neutron distances (Allen et al., 1987) (which were also recently summarised and updated by Allen \& Bruno (Allen \& Bruno, 2010)). For the purpose of current study, due to the lack of some atoms in the UBDB databank we either transferred the parameters from the atoms with the most similar environments already present in the database, or modelled extra atoms manually according to the original procedure (Jarzembska \& Dominiak, 2012). In the case of structures containing more than one independent fragment in ASU, the fragment charges were scaled separately, and all moieties were kept neutral. The multipole expansion was truncated at the hexadecapole $\left(l_{\max }=4\right)$ and quadrupole $\left(l_{\max }=2\right)$ levels for all non-hydrogen and hydrogen atoms, respectively. In all cases the statistical weights (i.e., $w_{i}=1 / \sigma_{i}^{2}$ for $i$-th reflection) were applied, the atomic coordinates, ADPs and scale factor were refined, whereas all multipolar parameters were kept fixed. The JANA program allows for the application of specific constraints and restraints during the refinement. Consequently, in all the refinements carried out, the hydrogen atom $U_{\text {iso }}$ parameters (i.e. isotropic thermal parameter) were constrained to the value of $y \cdot U_{\text {eq }}^{\mathrm{X}}(y=1.2$ and 1.5 for $\mathrm{X}=\mathrm{C}$ and $\mathrm{X}=0$ or N , respectively). The $\mathrm{X}-\mathrm{H}$ distances were restrained to the literature values with $\sigma=$ 0.001 (where an appropriate restraint weight is obviously equal to $1 / \sigma^{2}$ ). In case of disordered structures some extra restraints and constraints were also used. Such a procedure was found to reproduce very well the neutron-diffraction-quality geometries (Jarzembska et al., 2012). For details characterising all refinements see Table 1S.

Table 1S. Selected X-ray data collection, processing and refinement parameters for all presented crystal structures.\#
