Supporting information for article:

Ab initio structure determination of nanocrystals of organic pharmaceutical compounds by electron diffraction at room temperature using a Timepix quantum area direct electron detector. Corrigendum
E. van Genderen, M. T. B. Clabbers, P. P. Das, A. Stewart, I. Nederlof, K. C. Barentsen, Q. Portillo, N. S. Pannu, S. Nicolopoulos, T. Gruene and J. P. Abrahams

Figure S1: A short wavelength leads to greater errors in the unit cell parameters. At short wavelengths typical to electron diffraction, $\lambda=0.0251 \AA$, the maximum diffraction angle $2 \theta$ is very small. See text for details.

## S1 Camera Length and Cell Parameters

The wavelength used for electron diffraction is typically about $\lambda \approx 0.025 \AA$, whereas in X-ray diffraction, it is about $\lambda \approx 0.5-1.5 \AA$. With a maximum resolution of $1 \AA$, common for crystals from organic, the short wavelength leads to a small maximum diffraction angle, $2 \theta_{\max } \approx 1-2^{\circ}$, as opposed to $2 \theta_{\max } \approx 40-170^{\circ}$ in X-ray diffraction. In order to calculate the reciprocal lattice, the recorded diffractions are projected onto the Ewald sphere. At short wavelength, even a threefold greater camera lengths leads to only small distortions of the lattice. Therefore, uncertainties in the detector distance have much greater effect on the accuracy of the unit cell parameters. This is illustrated in Fig. S1.

## S2 Structure Solution

Data processed with XDS were solved with SHELXT. As we could not use the default options, we list the options for each data set here together with a summary of the results:

## Carbamazepine, Single Crystal (Table 1)

## S3 Merging Data

The main article shows data statistics for single data sets from carbamazepine and from nicotinic acid. We collected additional data sets from five different crystals for carbamazepine and two different crystals for nicotinic acid in order to see how merging affects the data. The data are shown in Table S1 and Table S2 respectively. The merging statistics in both cases are worse than for the single data sets, and structure solution with SHELXT required more options (see Sec. S2. It is not clear whether this is due to the effect of dynamic scattering. The amide group of carbamazepine can be oriented in two ways. During structure refinement against a data set of a single crystal we could observe a difference in $R 1$ between both possibilities, so that one crystal appears to crystallize with a preferred orientation. Several crystals may be a mixture of either orientation which could be a reason for the poor statistics. However, this is only a hypothesis. As this question is not the central question of this work, we did not investigate the effect at this stage.

Data were merged using POINTLESS/AIMLESS [1] as merging with XSCALE produced worse results. We are currently investigating the reasons. Note that AIMLESS has more strict rejection criteria than XSCALE, hence the sum of reflections in Table S4 from each crystal is greater than the total number of reflections for the merged data set. POINTLESS calculates a weighted averaged cell from the unit cell parameters.

Table S1: Data processing statistics of XDS from five different carbamazepine crystals and $R-$ values from refinement with SHELXL. Res: resolution range, high resolution shell in brackets where applicable. Compl: \% Completeness. Refl: Total number of reflections.

## S4 Model Quality

In order to assess the data quality beyond the statistical descriptors in Tables 1 and 2, a comparison of the bond lengths and angles for carbamazepine with the values published by [2] is shown in Tables S3 and S4. All structures were refined without restraints. Standard uncertainties as provided by SHELXL.

Table S3: Bond lengths for carbamazepine in comparison with the high resolution structure by [2]. single: single crystal data set. Table $1 ; 5 x$ merged: merged data from five crystals, Table S1. Lengths listed in $[\AA]$.

## S5 Data Processing and Structure Solution with ADT3D / PETS and SIR2014

For analysis with $A D T 3 D$ [4]/PETS [5], adjacent frames were summed to ensure a rotation range of $\approx 1.0^{\circ}$ per frame. Background correction and centering of the diffraction pattern with respect to the direct beam was performed. First, the rotation axis was determined using ADT3D/PETS, then the 3D reciprocal lattice vector space was reconstructed using ADT3D/PETS, allowing unit cell determination. Using the unit cell parameters, reflections were automatically indexed and

intensities extracted. For intensity extraction, no further corrections (like Lorentz polarization) were performed. The extracted intensities allowed ab initio structure solution using direct methods implemented in SIR2014 for the case of carbamazepine and simulated annealing technique for nicotinic acid compound. For structure solution, the kinematical approximation was used, where $I \propto F^{2}(h k l)$, which proved to be sufficient.
$A D T 3 D$ integrates reflections from the entire frames. The resolution cut-off was subsequently chosen by SIR2014 based on the useful data.

## S5.1 Carbamazepine

Using ADT3D / PETS we analyzed the same rotation diffraction data of carbamazepine processed with $X D S$ having a tilt range of $-25^{\circ}-26^{\circ}$, see Table 1 . For data processing, blocks of 55 adjacent frames were summed to create a data set with an angular increment of $\approx 1.0^{\circ}$ per frame, which was required for $A D T 3 D$. The obtained unit cell parameters ( $a=7.68 \AA, b=11.44$ $\AA, c=13.92 \AA, \alpha=89.39, \beta=91.22^{\circ}$, and $\gamma=89.43$ ) are consistent with the literature values [2]. A total number of 3868 reflections were extracted from the collected data, after applying the $(2 / \mathrm{m})$ monoclinic Laue symmetry 1940 reflections were left over.

The space group $P 2_{1} / n$ was automatically recognized by SIR2014 (figure of merit 0.88 ). Structure solution for carbamazepine was possible in one step using direct methods (SIR2014) with an initial residual value of $34.91 \%$ with 4 ghost atoms, 2 C atoms were assigned as N ,
$\mathrm{O} / \mathrm{N}$ atoms were not assigned and after the refinement the $R 1$ value reaches to $38.9 \%$. During refinement rigid body restraint was used for one of the benzene rings and all the atoms were refined isotopically.

A comparison of bond lenghts and selected 1,3-angles with literature values is presented in Tables S8 and S9 respectively.

Table S8: Bond lengths for carbamazepine refined with SIR2014 against data processed with ADT3D / PETS in comparison with the high resolution structure by [2]. See also Table S7. Lengths listed in [ $\AA$ ].

## S5.2 Data Processing for Nicotinic Acid

Continuous rotation data was collected using a 200 nm thin nicotinic acid nanocrystal. The whole tilt range spanned $36^{\circ}$ in total, with the tilt range from $-26^{\circ}-10^{\circ}$ with an angular increment of $0.05^{\circ}$ (see Table 1). Data processing with $A D T 3 D$ required summing 21 adjacent frames for $1^{\circ}$ tilt. The unit cell parameters $(a=7.19 \AA, b=11.74 \AA, c=7.28 \AA, \alpha=89.62$, $\beta=112.45^{\circ}$, and $\gamma=90.35$ ) are consistent with the literature values [3]. After intensity extraction based on the obtained unit cell, the total number of reflections was 1032 with a resolution of up to $0.78^{\circ} \AA$. The space group $P 2_{1} / c$ was suggested by SIR2014 with a figure of merit 0.137 . However, ab initio structure solution using SIR2014 was not successful as the data completeness
