MSnO_3 ($\text{M} = \text{Sr}, \text{Mg}$) nanoparticles were synthesized successfully using a facile microwave solvothermal route followed by further heat-treatment. Well-crystallized SrSnO_3 and MgSnO_3 nanoparticles were formed after heat-treatment at 800 °C for 3 h showing a fine and homogeneous morphology with particle sizes of 20–40 nm for SrSnO_3 and 50–200 nm for MgSnO_3 . The synthesized SrSnO_3 and MgSnO_3 nanoparticles were characterized by X-ray diffraction, Fourier transform infrared spectroscopy, scanning electron microscopy and transmission electron microscopy.

Key Words: SrSnO_3 , MgSnO_3 , Nanoparticles, Microwave irradiation, Solvothermal process.

INTRODUCTION

Metal metastannates, with structures closely related to the perovskite one, are of particular interest due to their unusual dielectric and semiconducting properties, leading to various applications such as thermally stable capacitors, ceramic dielectric bodies, gas and humidity sensors and battery electrode materials^{1,2}. Cubic perovskite type of metal stannates (MSnO_3) have attracted considerable attention for potential applications. It has been observed that a partial substitution of cations at M/Sn sites results in substantial modification in their physical properties so as to make them suitable for a wide variety of industrial applications^{3–5}. Metal metastannates have attracted considerable attention for potential applications in ceramic dielectric bodies, gas and humidity sensors, thermally stable capacitors and battery electrode materials^{1–5}.

Several processes have been developed over the past decade to enhance the applications of metal metastannates prepared by a range of processes, such as a solid-state reaction⁶, a co-precipitation method⁷, sol-gel⁸, a combustion method⁹, a precursor route^{10,11}, a microwave synthesis¹², a polymerized complex method¹³, a molten salt synthesis¹⁴, a pulsed laser deposition¹⁵, a self-heat-sustained method^{16,17}. The advantages of microwave synthesis are to bring a short reaction time, a small particle size and a narrow particle size distribution. Microwave energy is delivered to the surface of the material by radiant and/or convection heating, which is transferred to the bulk of the material *via* conduction to the material through molecular interactions with an electromagnetic field¹⁸. Hydro-

thermal process is an efficient low temperature method that allows the formation of particles with high degree of crystallinity and easy dispersion in an aqueous medium. The use of microwave energy in hydrothermal system promotes the development of a rapid heating to the required temperature with rapid rates of crystallization^{19,20}.

The microwave solvothermal process is adjusted to heat the metal stannates uniformly resulting in fine particles with a controlled morphology and to fabricate the product in a green manner without the generation of solvent waste. Recently, microwave solvothermal processes have been reported the use of a facile and fast method in preparing nanocrystalline particles of metal tungstates with unique and enhanced properties^{21,22}. When the solvent is ethylene glycol, the reactions proceed in a sealed pressure autoclave at temperatures above boiling point of the ethylene glycol. Microwave solvothermal process using a solvent of ethylene glycol is a facile process that provides a high-qualified yield with cost-effective method in short time periods.

In this study, SrSnO_3 and MgSnO_3 nanoparticles were synthesized using a facile solvothermal route assisted by the microwave irradiation. The characteristics of the synthesized SrSnO_3 and MgSnO_3 nanoparticles are discussed in detail based on the microwave solvothermal reaction in ethylene glycol under the high sealed pressure. The synthesized SrSnO_3 and MgSnO_3 nanoparticles were characterized by X-ray diffraction, Fourier transform infrared spectroscopy, scanning electron microscopy and transmission electron microscopy.

EXPERIMENTAL

Fig. 1 shows a flow chart for the synthesis of SrSnO_3 and MgSnO_3 nanoparticles by the microwave solvothermal process. $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$, $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$, $\text{Na}_2\text{SnO}_3 \cdot 3\text{H}_2\text{O}$ and ethylene glycol of analytical reagent grade (Aldrich) were used to prepare the of SrSnO_3 compound. Each of 0.01 mol $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$ and 0.01 mol $\text{Na}_2\text{SnO}_3 \cdot 3\text{H}_2\text{O}$ for SrSnO_3 was dissolved in 30 mL ethylene glycol. In the same way, each of 0.01 mol $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ and 0.01 mol $\text{Na}_2\text{SnO}_3 \cdot 3\text{H}_2\text{O}$ for MgSnO_3 was dissolved in 30 mL ethylene glycol. The solutions were mixed and adjusted at a pH 9.5 using NaOH. The aqueous solution was stirred at room temperature. In the sequence, the mixture was transferred into a Teflon-lined digestion vessel of 120 mL capacity. The Teflon vessel was placed into a microwave solvothermal autoclave (2.45 GHz, maximum power of 800 W). The microwave solvothermal conditions were kept at 200 °C for 0.5 h. After microwave solvothermal process, the microwave autoclave was cooled at room temperature. The resulting solutions were treated with ultrasonic radiation and washed many times with distilled hot water. The white precipitates were corrected and dried at 100 °C in a dry oven. The final products were heat-treated at 800 °C for 3 h.

Fig. 1. Flow chart for the synthesis of MSnO_3 ($\text{M} = \text{Sr}, \text{Mg}$) nanoparticles by the microwave solvothermal process

The existing phases of the SrSnO_3 and MgSnO_3 particles after the microwave solvothermal process were identified by powder XRD ($\text{CuK}\alpha$, Rigaku D/MAX 2200, Japan). FTIR (Nicolet IR 200, Thermo Electron Corporation, USA) was used to examine the absorption behaviour of the synthesized SrSnO_3 and MgSnO_3 particles over the frequency range, 400 to 4000 cm^{-1} . The microstructure, particle morphology and qualitative compositions of the SrSnO_3 and MgSnO_3 particles were observed by SEM (JSM-5600, JEOL, Japan) and TEM (JEM 2000-FX, 250 kV, Japan).

RESULTS AND DISCUSSION

Fig. 2 shows XRD patterns of the SrSnO_3 nanoparticles synthesized by the microwave solvothermal process after heat-treatment at 800 °C for 3 h. All XRD peaks could be assigned

to an orthorhombic structure of SrSnO_3 (JCPDS: 09-0086)¹². These suggest that microwave solvothermal synthesis is suitable for the growth of SrSnO_3 crystallites with the strongest major intensity peaks from the (210), (220) and (400) planes with some preferred orientation, respectively. Fig. 3 shows XRD patterns of the MgSnO_3 nanoparticles. All XRD peaks could be assigned to an orthorhombic structure of MgSnO_3 (JCPDS: 30-0798)⁷. These suggest that microwave solvothermal synthesis is suitable for the growth of MgSnO_3 crystallites with the strongest major intensity peaks from the (104), (110) and (024) planes with some preferred orientation, respectively.

Fig. 3. XRD patterns of the MgSnO_3 nanoparticles

Fig. 4 shows FT-IR spectra of the SrSnO_3 and MgSnO_3 nanoparticles in the wavenumber range, 4000–480 cm^{-1} . The very strong absorbable peak at 629 cm^{-1} in Fig. 4(a) reveals typical characteristics of a strong Sr-O stretching mode. The strong Sn-O stretching modes are contributed to the uniform regular SrO_6 octahedra of the metal stannates¹². The bands at 856 and 1050 cm^{-1} are due to the presence of carbonates. The bands at 2350, 1640 and 1450 cm^{-1} are assumed that the samples prepared contain a small amount of surface-adsorbed water and alcohol⁹. The very strong absorbable peak at 629 cm^{-1} in Fig. 4(b) reveals typical characteristics of a strong Mg-O stretching mode. The strong Mg-O stretching modes are contributed to the uniform regular MgO_6 octahedra of the metal stannates¹². The bands at 856 cm^{-1} due to the presence of carbonates.

Fig. 5 shows a SEM image (a) and a TEM image (b) of the SrSnO_3 nanoparticles. The SEM image of SrSnO_3 in Fig. 5(a) shows a well-defined and homogeneous morphology, while the TEM image of SrSnO_3 in Fig. 5(b) shows the particle sizes of 20–40 nm. Fig. 6 shows a SEM image (a) and a TEM image (b) of the MgSnO_3 nanoparticles. The SEM image of MgSnO_3 in Fig. 6(a) shows a well-defined and homogeneous morphology,

Fig. 4. FT-IR spectra of the (a) SrSnO_3 and (b) MgSnO_3 nanoparticles

while the TEM image of MgSnO_3 in Fig. 6(b) shows the particle sizes of 50–200 nm. The solvothermal synthesis proceeds the reactions between $\text{MCl}_2 \cdot 6\text{H}_2\text{O}$ and $\text{Na}_2\text{SnO}_3 \cdot 3\text{H}_2\text{O}$ in a hot ethylene glycol solution as a polar solvent above a boiling point of 197°C . The microwave solvothermal process of metal metastannates occurs in accordance with the reaction:

When the microwave radiation is supplied to the ethylene glycol under a sealed pressure above boiling point, the components dissolving in the ethylene glycol are charged and vibrated in electric field interdependently. The microwave solvothermal process is adjusted to heat the metal stannates uniformly resulting in fine particles with a controlled morphology and to fabricate the product in a green manner without the generation of solvent waste. The microwave-assisted solvothermal reaction involves the exchange of atomic/ionic species, where the driving force is the exothermic reaction in ethylene glycol accompanying the formation of NaCl with a high lattice energy. The microwave exothermic reaction occurs so rapidly that the temperature and the pressure of the ethylene glycol increases so quickly that the reaction products are essentially heated up. The microwave-assisted solvothermal reactions provide a facile and fast route for the synthesis of SrSnO_3 and MgSnO_3 nanoparticles at considerably lower temperatures with a high

pressure than those usually employed for their synthesis. The well-defined nanoparticles features synthesized by the microwave-assisted solvothermal process have a control over the morphology of the fine particles and can be used for technological applications.

Conclusion

SrSnO_3 and MgSnO_3 nanoparticles were synthesized successfully by the microwave solvothermal processes between $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$ and $\text{Na}_2\text{SnO}_3 \cdot 3\text{H}_2\text{O}$ for SrSnO_3 and $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ $\text{Na}_2\text{SnO}_3 \cdot 3\text{H}_2\text{O}$ for MgSnO_3 in a hot ethylene glycol solution as a polar solvent. The microwave solvothermal reactions occurred so rapidly that the exothermic reaction was essentially used to heat up the metal metastannates. Well-crystallized SrSnO_3 and MgSnO_3 and nanoparticles were formed after heat-treatment at 800°C for 3 h showing a fine and homogeneous morphology with particle sizes of 20–40 nm for SrSnO_3 and with particle sizes of 50–200 nm for MgSnO_3 . The very strong absorbable peak at 629 cm^{-1} was typical characteristics of a strong Sr-O and Mg-O stretching modes.
