The molecule oxygen (O_2) activated on cobalt tetraphenylporphyrin (CoTPP) to form the peroxide species $CoTPPO_2$, which is the key intermediate in the behavior of metalloporphyrin catalyzed hydrocarbon oxidation, was simulated by the quantum chemical calculations. The effect of the *meso*-phenyl ring on the formation of the peroxide species $CoTPPO_2$ was investigated for the first time. The molecular geometry studies indicated that the *meso*-phenyl ring rotated with the molecule oxygen coordinated with CoTPP. Further nature atomic charge and nature bond orbital analysis supported that the steric changing of the *meso*-phenyl has a positive effect on the electron transport between CoTPP and O_2 to form the peroxide intermediate.

Keywords: Cobalt porphyrin, Oxygen, Catalyst, Quantum chemical.

INTRODUCTION

As a model of cytochrome P-450 mono-oxygenase, metalloporphyrin catalyzed hydrocarbon oxidation under mild condition has been studied systematically by many groups in the last decades¹⁻⁷. Previous studies⁸⁻¹¹ showed that the molecular oxygen can be activated on metalloporphyrin surface to form the peroxide species $MP-O_2$. With the further O-O bond broken, the reactive intermediate $[MP=O]^+$ can be available to oxidate the C-H bond of the different kinds of hydrocarbon. It was observed that the intermediate $[PFe^{IV}=O]^+$ can be formed in the cytochrome P-450 catalyzed reaction by the EPR and the crystal studies¹. Some theoretical studies^{12,13} also supported the existence of the manganese oxo intermediate $Mn=O$. Since the importance of the peroxide species $MP-O_2$, a few papers have been published to describe the coordination of the metal ion and the molecular oxygen based on iron porphyrin and manganese porphyrin¹⁴⁻³⁴. For example, an end-on configuration complex $FeP-O_2$ was calculated by the density functional theory (DFT)²⁸ and the manganese oxo species $MnP-O_2$ was also simulated by DFT calculations²².

In contrast to the fruitful reports of the center metal ion and the oxygen ligand, there are few reports to clarify the structure information of the peripheral substitutes such as *meso*-phenyl groups. But a lot of evidences have supported that the peripheral substitutes have significant influences on the properties of the metal porphyrins²⁹⁻³¹. The catalytic activities

of porphyrins have been proved to be linear correlation with the electrical properties of different peripheral substitutes by our group³¹⁻³³. For better understanding the relevant law of the peripheral substitutes on porphyrin, the *meso*-phenyl groups on CoTPP was investigated on the distribution of the geometry structures and the electrons before and after the peroxide species $CoTPPO_2$ formed by the quantum chemical method.

EXPERIMENTAL

Calculation for structure of CoTPP: The initial geometry of CoTPP was built based on the crystal structure data with D_{4h} point group symmetry assumed³⁵. The total energy and the electronic energy of two kinds of spin multiplicities ($S = 1/2, 3/2$) were calculated by semi-empirical PM3 implemented in the soft package Hyperchem 7.0 (Hypercube Inc., USA) to confirm the ground state of CoTPP. The Polak-Ribiere conjugate gradient algorithm was applied during the calculation³⁶⁻³⁸. Further DFT optimizations for CoTPP were performed Lee. Yang and Parr correlation (B3LYP) with the 6-311G basis set employed³⁹⁻⁴¹. The optimized structure of CoTPP was show in Fig. 1.

Calculation for structure of peroxide species $CoTPPO_2$: At present, a few papers is reported to disclose the structure of the peroxide species $PM-O_2$ without the peripheral substitutes on the porphyrin ring such as $FeP-O_2$ and $MnP-O_2$. The substitutes such as the *meso*-phenyl rings were freezed or neglected to decrease the calculation consuming. The end-on and the

Fig. 1. Optimized structure of CoTPP

Fig. 2. Proposed intermediates for O₂ coordinate with metalloporphyrin

side-on configurations of the PM-O₂ shown in Fig. 2 can be available by these theoretical calculations^{22,25,39}.

In this paper, the original structure of the peroxide species CoTPPO₂ was built in both the end-on and the side-on configurations same as Fig. 2. The molecule oxygen was put above the center Co(II) ion at the distance about 3.0 Å with two different configurations. Cobalt(II) porphyrins commonly exist as the low spin electronic states differently and is insensitive to the ligand⁴⁰⁻⁴⁷. So CoTPPO₂ was considered as the low spin ($S=1/2$) statues. Further DFT geometry optimize calculations for CoTPPO₂ were performed at B3LYP/6-311G level without any geometry limits. The behavior of the *meso*-phenyl rings was also simulated. The natural atomic charges (NAC) and the natural bond orbital (NBO) parameters of CoTPP and CoTPPO₂ were also calculated accordingly. All of the DFT

studies were done on Dell 9150 PC (3.8GHz, 2GB) by using Gaussian03W soft package⁴⁴.

RESULTS AND DISCUSSION

The geometries of CoTPP in different spin multiplicities of S ($1/2$, $3/2$) optimized by PM3 method are illustrated in Fig. 1. The energies listed in Table-1 indicate that the total energy of $S = 1/2$ state is about 52.75 kcal/mol lower than $S = 3/2$ state. So the ground electronic state of CoTPP is the low spin $S = 1/2$ which is same as the ESR experimental results reported by Liao *et al.*^{40,45}.

TABLE-1 ENERGIES IN DIFFERENT SPIN MULTIPLICITIES OF CoTPP (kcal/mol)		
Energy	$S = 1/2$	$S = 3/2$
Relative total energy	0.0000	52.75
Binding energy	-9534.89	-9482.14
Isolated atomic energy	-153775.73	-153775.73
Electronic energy	-1812372.20	-1830058.27
Core-core interaction	1649061.57	1666800.40

The DFT optimized structure parameters were partially summarized in Table-2. The structural data indicated that the DFT optimized structure of CoTPP is very close to the crystal structure. And the vibration frequency analysis has also been done on the optimized CoTPP and CoTPPO₂ to confirm the stability of these structures. A final end-on configuration of CoTPPO₂ is available after the DFT geometry optimization whatever the initial position of O₂ is the side-on or the end-on. It is different from those theory calculation results reported previously^{22,25,39} which ignored the *meso*-phenyl rings during the analog computation.

As the optimized structures shown in Fig. 3, the macro cycle of CoTPP is almost a plane with the *meso*-phenyl rings perpendicular to it. With the axial O₂ ligand coordinated with

the central Co atom, two obvious geometrical changes were happened on CoTPP. First, the macro cycle of CoTPP turned to be slight bending to form a saddle type which has been proved to be a low energy configuration. The second, the *meso*-phenyl rings rotated and formed a 74.5° dihedral angle (ϕ) with the macro cycle of CoTPP. At the same time, the axial O₂ ligand draw close to the central Co atom as the end-on configuration. The Co29-O79 distance decreased from 3.000 Å to 2.053 Å and the O78-O79 distance increased from 1.256 to 1.287 Å. The Co-O-O angle $\angle$ Co29-O79-O78 of the final optimized CoTPPO₂ is about 122.2°. The geometrical data indicated that the O-O bond was weakened after the coordination, which means the O₂ was activated by CoTPP. The weakened O-O bond would be more easy to be broke and form the reactive intermediate TPPCo=O to oxidate the C-H bond of the hydrocarbons.

The optimized structures showed that the *meso*-phenyl rings of CoTPP were rotated when coordinated with the molecular O₂. There would be some steric effects for the active potential of cobalt porphyrin molecule. Further electrical analysis was performed to disclose the effects of these steric changes on CoTPP catalyzed activation of O₂. The nature atomic charges of the oxygen atoms were calculated while the dihedral angle (ϕ) was changed from 90° to 74.5°. It was obviously that the charges on the oxygen atoms were increased by -0.3792e with the rotation of the *meso*-phenyl rings. The π bond on the *meso*-phenyl ring would have some conjugative effect with the π -orbital on the macrocycle of CoTPP while the *meso*-phenyl ring rotated. There would be a part of electrons on the phenyl ring going through the porphyrin cycle and transferring to the centre Co atom while the Co atom combined with O₂ (Table-3).

The natural bond orbital (NBO) analysis results (Table-4) of CoTPP showed that the occupancies on $3d_{x^2-y^2}$ orbital of Co were increased from 0.5738e to 1.9765e after coordinated with the axial ligand O₂. Meanwhile, the occupancies on $3d_{xy}$ and $3d_{z^2}$ were decreased in some degree. The stabilizing energies of NBO analysis of CoTPPO₂ are listed in Table-5. It showed that the electron transfer from N atomic on porphyrin cycle to the central Co atom would be beneficial to the stability of the

coordination system and the electrons on the 3d-orbitals of Co also have the trend to transfer to the anti-bonding orbital of O₂. These theory calculations proved that the electron transfer direction can be described as phenyl $\rightarrow$ CoP $\rightarrow$ O₂. The steric changes of the *meso*-phenyl ring would enhanced the electron transfer from the phenyl ring to CoP cycle which will further be good to the activation of O₂. The *meso*-phenyl rotation

would be a positive action to promote CoTPP coordinate with the axial ligand O₂.

For the end-on configuration of the optimized CoTPPO₂, the molecular orbital theory put forward that the orbitals between the reactants should fit with symmetry. It is well known that the HOMO of O₂ is the π^* type orbital. It has the right symmetry to reacts with the d_{xy} orbital of the Co. The electron transfer from the d_{z²} of Co to the σ^* type orbital of O-O bond are also fit in the symmetry. These electron transfer directions are also well consistent with the NBO calculation results (Tables 4 and 5). Tracing back to the geometry changes of CoTPPO₂, the Co-O-O bended to form an angle about 122.2°. This geometry is favorable to the maximum overlap between the d_{z²} of Co and the σ^* type orbital of O₂, as well as more effective to the interaction between the d_{xy} of Co and the π^* type orbital of O₂. Furthermore, the electron transfer from the p_z of N to the d_{x²-y²} of Co is also allowed.

Conclusion

In summary, the quantum chemistry have been applied to investigate the molecular oxygen (O₂) activated on cobalt tetraphenylporphyrin (CoTPP). The stable end-on configuration of the complex CoTPPO₂ was available by the optimization. The geometrical structure of CoTPPO₂ showed that the *meso*-phenyl ring rotated when CoTPP coordinated with O₂ ligand. Further electrical analysis disclosed that this steric rotation would promote the electron transfer from the *meso*-phenyl ring to the CoP macro cycle, which would be beneficial to enhance the potential of CoTPP to activate the dioxygen. The molecular graphic studies also manifested that the weakened O-O bond was the portent of the final breakage of the O-O bond to form the TPPCo=O intermediate which is the key reactive species for the hydrocarbon oxidation. We believe all of these investigations will be useful for the future design of the novel high performance cobalt porphyrin catalyst.
