ABSTRACT

The Valles-San Luis Potosí Platform is part of an extensive carbonate platform system that rimmed the ancestral Gulf of Mexico during the middle (Albian) through Upper Cretaceous. The El Abra Formation consists of a shallow-water deposit; it contains a benthic foraminiferal assemblage that includes 18 species, which are described and illustrated in this paper. The studied successions from the upper part of the El Abra Formation were dated as mid-late Cenomanian. On the basis of these findings, two zones are proposed *Pseudolituonella reicheli* Assemblage Zone and *Nezzazatinella picardi* Interval Zone. The first Assemblage Zone is characterized by an abundant benthic foraminiferal association. It is overlain by the *Nezzazatinella picardi* Interval Zone where the species richness of the foraminiferal assemblage is reduced and later disappears. The benthic foraminiferal demise is coincident with major sea-level changes and an increase in siliciclastic input from the hemipelagic deposit of the Soyatal Formation, which contains abundant pithonellids and *r* and *r-k* strategist planktic foraminifera (*Whiteinella archaeocretacea* Partial Range Zone). Two stratigraphically correlative facies have been recognized in the El Abra Formation: the Taninul and the El Abra Facies. A warm, shallow-water, open marine platform deposit (Taninul Facies) is inferred. It includes peloidal-foraminiferal packstone, packstone-grainstone, and packstone-wackestone. A restricted environment (El Abra Facies) can be deduced from the abundant miliolids and ostreids. The texture is a wackestone-packstone. Another microfacies (Soyatal Formation) consists of wackestone-packstone with an acme of pithonellids and the occurrence of *r* and *r-k* strategist planktic foraminifera deposited during the platform drowning.

Keywords: Cenomanian, benthic foraminifers, El Abra Formation, San Luis Potosí, Mexico.

RESUMEN

La Plataforma Valles-San Luis Potosí es parte de un sistema de plataformas extenso que se encontraba bordeando el antiguo Golfo de México en el Albiano hasta el Cretácico Superior. La caliza El Abra es un depósito de aguas poco profundas; ésta contiene un conjunto de foraminíferos bentónicos que incluye 18 especies, que se describen e ilustran en este documento. Las sucesiones estudiadas de la parte superior de la Formación de El Abra fueron datadas como del Cenomaniano medio-tardío; se proponen dos zonas (*Zona de Conjunto Pseudolituonella reicheli* y *Zona de Intervalo Nezzazatinella picardi*). La primera *Zona de Conjunto* se caracteriza por una asociación abundante de foraminíferos bentónicos. Está sobrepasada por la *Zona de Intervalo Nezzazatinella picardi* donde se reduce la riqueza de especies de las asociaciones de foraminíferos y luego desaparece. La desaparición de foraminíferos bentónicos es coincidente con grandes cambios de nivel del mar y un aumento en el aporte de sedimentos desde el depósito hemipelágico de la Formación Soyatal que contiene abundantes pithonélidos y foraminíferos planctónicos de estrategia *r* y *r-k* (*Zona de Alcance Parcial Whiteinella archaeocretacea*). Dos facies estratigráficamente correlacionables han sido reconocidas en la Formación El Abra: la *Facies Taninul* y la *Facies El Abra*. Se infiere un depósito de plataforma marina abierta de aguas cálidas someras (*Facies Taninul*). Ésta incluye un *packstone peloidal* con foraminíferos, *packstone* y *packstone-wackestone*. Un ambiente restringido (*Facies El Abra*) puede deducirse por los abundantes miliólidos y ostreídos. La textura de la roca es un *wackestone-packstone*. Otra microfacies consiste de un *wackestone-packstone* con un auge de pithonélidos y la presencia de foraminíferos de estrategia *r* y *r-k* depositados durante la inundación de la plataforma (Formación Soyatal).

1. Introduction

During the mid-Cretaceous, particularly in the Albian through Cenomanian, widespread carbonate platform development took place throughout the tropical-subtropical shallow-water environments of the Tethys (Schroeder and Neumann, 1985, p. 5). Benthic foraminifers and algae are the most important groups that inhabited this milieu. In Mexico, during the Albian/Cenomanian, the Valles-San Luis Potosí Platform (VSLPP) was part of a wide carbonate platform system that bordered the ancestral Gulf of Mexico (Salvador, 1991). This platform experienced the evolution of a rich and diverse benthic foraminiferal assemblage now contained in the El Abra Limestone.

In this study, we analyzed calcareous samples derived from the Cenomanian El Abra Formation containing an abundant and well-preserved benthic foraminiferal assemblage that also includes algae, corals, echinoderms, and annelids.

The El Abra Formation is renowned for its invertebrate fossils, primarily Albian rudists, which have been analyzed by numerous authors (*e.g.* Adkins, 1930; Coogan, 1973; Alencáster, 1998; Alencáster and García-Barrera, 2008).

The Albian benthic foraminifers from the El Abra Formation were documented by Bonet (1956), and Tavitás and Solano (1984) from the eastern part VSLPP. They reported an assemblage composed of *Orbitolina* (*Mesorbitolina*) *texana*, *Dictyoconus walnutensis* (Carsey), *Coskinolina sunnilandensis* (Maync), *Pseudonummoloculina heimi* (Bonet), and *Dicyclina schlumbergeri* (Munier-Chalmas).

We studied the benthic foraminiferal community from the western part of the VSLPP. This association has been dated as middle-late Cenomanian and is very different from the well-known foraminiferal association of the eastern part composed mostly of orbitolinids (Omaña *et al.*, 2016).

The upper part of the El Abra Formation in the area of study represents the last shallow-water deposit preceding the VSLPP, which was drowning at the Cenomanian/Turonian boundary interval (Basañez *et al.*, 1993; Omaña *et al.*, 2012). It is overlain by a succession of bioclastic packstone

and pelagic wackestone bearing planktic foraminifers and pithonellids (Soyatal Formation).

The drowned episode in the Cenomanian/Turonian (C/T) interval at the global level is linked with rising sea level (Haq *et al.*, 1987; Haq, 2014; Hallam, 1992; Miller *et al.*, 2005; Gale *et al.*, 2008), and widespread flooding of Mediterranean platforms (Drzewiecki and Simó, 1977; Caus *et al.*, 1997; Hart *et al.*, 2005; El-Sabbagh *et al.*, 2011; Korbar *et al.*, 2012).

The start of the demise of the carbonate platforms occurred during the latest Cenomanian (*Whiteinella archaeocretacea* Zone), with a major biological change that affected benthic organisms such as rudists and larger benthic foraminifera.

Philip and Airaud-Crumière (1991, p. 117) documented that the benthic foraminifera were affected in two steps; the genera *Praealveolina*, *Chrysalidina*, *Pseudocyclammina*, and *Pseudolituonella* disappeared at the top of *Geslinianum* Zone. During the late Cenomanian (*Juddii* Zone) the benthic foraminifera were scarce and poorly diversified miliolids, textularids, and trochamminids. At second step occurs when a major extinction affected the benthic foraminifera at the C/T boundary.

Parente *et al.* (2008) also reported a two-step pattern of extinction of larger foraminifers in the upper Cenomanian in shallow-water carbonates of the southern Apennines (Italy). They stated that “the first step eliminated the alveolinids, the most extreme *k* strategists, reducing the diversity of the larger foraminifera to less complex forms such as *Chrysalidina*, *Pseudolituonella* and *Pseudoraphydionina*; when the high productivity persisted only *r*-opportunistic planktic foraminifers predominated while the rise of the mesotrophic threshold triggered the second step extinction of larger foraminifera.”

However, in the present study, the C/T boundary interval is characterized by the disappearance first of larger forms such as *Pseudolituonella*, *Daxia*, *Merlingina*, *Hemicyclammina*, *Dicyclina*, and *Cuneolina*. Later, only forms such as *Nezzazatinella picardi*, *Praechrysalidina*, rotalids, miliolids, and algae remained, this interval is overlain by a deposit with abundant pithonellids, and *r* and *r-k* strategist planktic foraminifers.

minifers with simple morphologies, such as *Hedbergella*, *Heterohelix*, *Globigerinelloides*, and *Whiteinella* as a result of flooding of the platform.

The objectives of the work are a) to describe and illustrate the benthic foraminifers identified from the upper part of the El Abra Formation as a contribution to the knowledge of the faunal assemblage of this unit in Mexico and of the western part of the Tethys Realm; b) to provide information about the distribution of the larger foraminifers before their demise, caused by the flooding of the VSLPP; c) to constrain the age of the El Abra Formation using the stratigraphic value of the benthic foraminifers, comparing the biostratigraphic standards based on them in the

peri-Tethyan area; moreover, supporting it from the planktic age of the overlying unit; and d) to integrate the paleoecological data of the larger foraminifers and the microfacies study to infer information about the paleoenvironment.

2. Geological setting

The samples were collected east of the city of San Luis Potosí (Figure 1). This area belongs to the western part of the VSLPP, which formed in association with the opening of the Gulf of Mexico. According to Salvador (1991), the Early Cretaceous was a time of significant tectonic stability in the Gulf of Mexico Basin. During this period,

the influx of terrigenous sediment decreased and the stable shelves, ramps, and platforms bordering the deep central part of the basin became the site of widespread carbonate deposition, particularly during the Albian, when carbonate deposition extended from the Bahamas along the northern rim of the Gulf, across Mexico to the Yucatan Peninsula, and to various Caribbean localities (Scott, 1990). Along the western flank of the basin in east-central Mexico, carbonate platforms were more locally restricted, such as the VSLPP (Figure 2), which remained active until the Cenomanian. Wilson and Ward (1993, p. 42) stated that the VSLPP is one of “the largest isolated carbonate platforms (200 by 300 km) located on the western side of the Gulf of Mexico. It initiated in the Early Cretaceous, but reached its maximum area in the Albian, when it evolved a rimmed shelf margin. The platform apparently formed along the southwestern flank of a north-northwest-trending tectonic ridge of Precambrian gneiss and Upper Paleozoic schist that is exposed at Miquihuana, 70 km southwest of Ciudad Victoria on the state line between Nuevo León and Tamaulipas”.

Recently, Venegas-Rodríguez *et al.* (2009) stated that the VSLPP overlies Toarcian rocks dated by detrital zircon from the El Alamito locality at W Río Verde, San Luis Potosí. It is interpreted by these authors as a deposit from the paleo-Pacific margin occurring at same time as the opening of the Gulf of Mexico.

The VSLPP now lies within the Sierra Madre Oriental fold-thrust belt (Suter, 1984; 1987). Its eastern shelf margin is exposed in quarries along the Cuesta de El Abra near Valles and Antiguo Morelos (km 541–546 of the San Luis Potosí–Tampico railway). Part of its western side can be seen along road cuts 30 km east of the city of San Luis Potosí. The stratigraphic framework for the VSLPP has been described by Cserna and Bello-Barradas (1963), Carrillo-Bravo (1971), Suter (1990), Basañez (1993), Wilson and Ward (1993), and Torres-Hernández (1994). The depositional process has been recorded by Enos and Stephens (1993), Aguayo (1998), and López-Doncel (2003).

3. Materials and Methods

The studied material comes from the upper part of the El Abra Limestone (Figure 2). It was collected from four sections that ranged from 40 to 100 m thick located at the western part of the VSLPP: Llano del Carmen (LLC), Guadalcázar (G), Cerritos (C), El Temazcal (ET), as well as in the La Minita outcrop (LM).

The samples were collected at an average interval of 5 to 10 m. The 150 thin sections were prepared both parallel and perpendicular to the stratification for foraminiferal and microfacies examination. The faunal preservation is good, which permitted precise identification; the biostratigraphic scheme is based on the benthic and planktic foraminiferal stratigraphic ranges. In addition, a microfacies study was carried out to reconstruct the paleoenvironment.

4. Results and Discussion

4.1. LITHOFACIES AND MICROFACIES

The El Abra Formation displays two facies, the Taninul and El Abra, which are stratigraphically correlated (Aguayo, 1998). The Taninul facies is a thick to massive skeletal bioclastic limestone mostly composed of rudists, foraminifers and algae (Figure 3a to 3c). The El Abra facies is a light gray limestone rich in miliolids and ostreids (Figure 3e and 3f).

4.1.2. THE TANINUL FACIES

The following sections were measured, sampled, and described from the Taninul facies.

4.1.2.1. LLANO DEL CARMEN SECTION (LLC)

The Llano del Carmen section (LLC) currently crops out north of the city of San Luis Potosí (coordinates 22°45'N, 100°40'W). It consists of massive dark-gray limestone of the El Abra Formation and is ~100 m thick (Figure 4).

Figure 2 Geological map showing the El Abra and Soyatal Formations (modified from Labarthe *et al.*, 1982; López-Doncel, 2003).

The petrographic analysis indicates a peloidal packstone-grainstone with high foraminiferal species richness that includes *Pseudolituonella reicheli*, *Daxia cenomana*, *Hemicyclammina sigali*, *Merlingina cretacea*, *Pseudocyclammina* sp., *Dicyclina schlumbergeri*, *Cuneolina pavonia*, *Cuneolina parva*, *Nezzazata gyra*, *N. simplex*, *Nezzazatinella picardi*, *Spiroloculina cenomana*, *Peneroplis parvus*, and *Minouxia inflata*. The algae *Bouenia* sp. and encrusting *Lithocodium aggregatum* are present. The components of more than 60% of the content can be recognized. They are embedded in microsparitic cement, densely

packed in a matrix-supported fabric. Most of the components are coated with micrite, suggesting moderate transport into a relatively high-energy environment. The lithology and faunal-algal assemblage indicates a deposit in a normal-marine open platform not subjected to significant restriction in water circulation. It is important to note that rudist *Hippurites resectus* is also found in this association.

Other microfacies consist of a coated, poorly sorted foraminiferal grainstone consisting of miliolids and other forms such as *Peneroplis parvus*,

Figure 3 Microfacies of the upper part of the El Abra Formation. Scale bars 100 μm . a: Packstone-grainstone (Sample ET-2); b: Grainstone poorly classified with miliolids (Sample LLC-4); c: Worn algal packstone (Sample C-9); d: Calcsphere-rich packstone-wackestone (Sample C-10); e: Wackestone-packstone with a great abundance of miliolids and thin-shelled ostreids oriented in a parallel arrangement (Sample LM-1); f: Benthic foraminiferal wackestone-packstone (Sample LM-5).

and algae; the grains and microfossils are strongly micritized (Figure 3b).

4.1.2.2. THE GUADALCÁZAR SECTION (G)

The Guadalcázar section (G) is located NE of the city of San Luis Potosí (22°64'N, 100°38'W). The

studied succession belongs to the upper part of the El Abra Formation that crops out in the Aguaje de los García stream. It consists of a gray calcareous deposit ~50 m thick of the Taninul Facies (Figure 5). The lithofacies is dominated by packstone and subordinate grainstone with the same foramin-

Figure 4 Llano del Carmen section.

iferal assemblage as the Llano del Carmen site but containing algae, such as *Salpingoporella hasi* and *Clypeina* sp.

The presence of sparitic cement represents an increase in energy in practically the same microfacies as at the Llano del Carmen site. This microfacies is interpreted as Standard Microfacies Type (SMF) 18 (Flügel, 2004) of Facies Zone 7 to 8 (Wilson, 1975) in the platform (open marine). The El Abra limestone is unconformably overlain by the Soyatal Formation, which here is 15 m thick.

4.1.2.3. THE CERRITOS SECTION (C)

The Cerritos section (C) was measured on the San Luis Potosí–Cerritos road (22°43'N, 100°28'W). It

consists of 45 m of massive gray limestone from the upper part of the El Abra Formation of the Taninul Facies, and it is conformably overlain by the Soyatal Formation (Figure 6).

In the El Abra Formation we recognized the following 2 microfacies:

Microfacies 1–Benthic foraminiferal packstone–grainstone rich in pellets and pseudopellets. The percentage of components locally exceeds 50%, forming a grain-supported fabric. The ground-mass, mostly sparry cement, shows small remains of an original micritic matrix. The microfacies type could be comparable to SMF 18 “bioclastic grainstones and packstones with abundant benthic foraminifera or calcareous green algae” (Flügel, 2004).

Figure 5 Guadalcazar section.

The depositional environment of this microfacies suggests a shallow marine environment above the normal wave base, within the euphotic zone in the open marine interior platform, corresponding to Facies Zone 7 of Wilson (1975). The fossil assemblage indicates precipitation in shallow subtidal zones with normal salinity, stable temperature conditions, and good oxygenation of the seawater. Microfacies 2—Worn algal packstone, within a fine-grained matrix containing a larger embedded amount of algae (Figure 3c). The foraminiferal community is reduced to small forms of *Nezazatinella picardi*, miliolids, and rotalids. This change could be related to an increase in nutrient supply. This microfacies is similar to SMF 10, suggesting an open sea shelf environment of Facies Zone 7 of (Wilson 1975). The main components have been transported from high-energy to low-energy environments, and a variation in the water energy can

be inferred from the increase in size of the bioclasts and groundmass grains (microsparite). This microfacies corresponds to Facies Zone 7 (interior platform, open marine environment).

Up-section, the lithology changes to marly limestone of the hemipelagic–pelagic Soyatal Formation represented by the next microfacies:

Microfacies 3—Pithonellid-rich packstone–wackestone, this microfacies contains a bloom of pithonellids embedded in a micritic matrix that varies locally in microsparitic cement (Figure 3d). The population of pithonellids can be up to more than 50% of the components in a mud to grain-supported fabric. In addition to the pithonellids, *r* and *r-k* strategist planktic foraminifera are also present, including *Muricohedbergella delrioensis*, *M. planispira*, *Heterohelix moremani*, *Heterohelix reussi*, *Macroglobigerinelloides caseyi*, *Whiteinella archaeocretacea*, *W. cf. W. aprica*, *W. baltica*, *W. brittonensis*, and *W. paradubia*. The *r*-strategists are small to medium-sized species with unornamented tests and simple morphologies that have high reproductive potential and are adapted to eutrophic or unstable environments, and morphotypes as *Whiteinella* that connect the *r* and *k* morphogroups and are called *r/k*-intermediate species (Gebhardt *et al.*, 2010). Small benthic foraminifera *Dorothia* sp., *Gavelinella* sp., *Lingulogavelinella* sp., and roveacrinids were identified. No microlamination or orientation of the components is recognizable; rather, it resembles an unsorted accumulation of microfauna in the micritic groundmass. This microfacies could be similar to types SMF 2 and 3 Flügel (2004) (wackestone to packstone with pithonellids and foraminifers) and a Facies Zone 2 to 3 of Wilson (1975) (deep shelf), but its depositional environment is certainly evidence of an initial drowning event.

4.1.2.4. THE EL TEMAȚCAL SECTION (ET)

The analyzed section was measured in the Cerro Quemado locality (22°38'N, 100°50'W). It is composed of 40m of gray, massive limestone corresponding to the El Abra Formation, and is unconformably capped by a reddish calcareous shale unit.

Figure 6 Cerritos section.

The limestone in this locality has packstone–grainstone texture and locally the component exceeds 60%, forming a typical grain-supported fabric. The foraminiferal association is like that of the other sections, but the algae *Neomeris cretacea* is present. The standard microfacies type and the facies zone are similar to those at the other localities, which include SMF 8 to 10 in the Facies Zone 7 (Flügel, 2004; Wilson,1975).

4.1.3. THE EL ABRA FACIES

4.1.3.1. THE LA MINITA OUTCROP (LM)

At this locality (22°78 5'N, 100°85'W), we collected 8 samples of cream to light-gray limestone of the El Abra facies (Figure 7).

The La Minita outcrop displays several examples of cream limestone of the El Abra facies (40 m thick). Two microfacies are defined: 1) a wackestone–packstone with reduced diversity but a great abundance of miliolids and thin-shelled ostreids, which are well-oriented in a parallel arrangement (Figure 3e). The presence of benthic foraminifera suggests shallow-water settings and the arrangement points to some control by the current. The components are embedded in a micritic matrix with a mud-supported fabric. These characteristics are comparable to SMF 8 (Flügel, 2004) of Facies Zone 7 in the interior platform; and 2) another that shows a benthic foraminifer-rich wackstone–packstone with a higher diversity of

Figure 7 Temazcal section.

species including *Pseudonummoloculina heimi*, *Ovalveolina maccagnoae*, *Dicyclina schlumbergeri*, and *Cuneolina pavonia* (Figure 3f). The ground mass varies from micritic up to microsparitic and the fabric is much denser (grain-supported) in comparison with the first microfacies. This microfacies can be classified as SMF 10 to 11 of Facies Zone 7 in the interior platform with moderate energy.

4.2. AGE

Cretaceous larger benthic foraminifera are stratigraphically significant in shallow-water environments, where they are the most prominent marker fossils when other fossils such as the ammonites and planktic foraminifera are absent (Schroeder and Neumann, 1985).

Their stratigraphic value is based on their abundance, diversity, and evolutionary rates, which make these fossils a useful biostratigraphic tool for dating these deposits.

Few datings have been based on benthic foraminiferal studies from the western part of the VSLPP; consequently, this study provides a support for an accurate dating of this unit, which is determined as mid-late Cenomanian, comparable with those defined in other localities from the peri-Mediterranean area and southern Mexico. Moreover, it is an important contribution to the knowledge of the geographic distribution of these benthic foraminifera in the western part of the Tethys Realm.

In the interval studied we recognized two zones: *Pseudolituonella reicheli* Assemblage Zone and the overlain *Nezzazatinella picardi* Interval Zone.

4.2.1 PSEUDOLITUONELLA REICHELI

Assemblage Zone contains a foraminiferal assemblage composed of *Pseudolituonella reicheli*, *Hemicyclammina sigali*, *Daxia cenomana*, *Merlingina cretacea*, *Cuneolina pavonia*, *Cuneolina parva*, *Nezzazata gyra*, *N. simplex*, *Peneroplis parvus*, *Dicyclina schlumbergeri*, *Minouxia inflata*, *Nezzazatinella picardi*, *Spiroloculina cenomana*, *Pseudocyclammina* sp., and *Charentia* sp.

4.2.2. NEZZAZATINELLA PICARDI

Interval Zone, which overlies the *Pseudolituonella reicheli* Assemblage Zone which, is characterized by a change in the benthic foraminiferal assemblage in which the larger foraminifera *Pseudolituonella*, *Pseudocyclammina*, *Hemicyclammina*, *Daxia*, and *Merlingina* disappear, reducing the foraminiferal community to forms of *Nezzazatinella picardi*, *Rotorbinella mesogeensis*, *Praechrysalidina* sp., and miliolids. A proliferation of gymnocodaceans, such as *Permocalculus*, is observed. This association later also disappeared when the platform was drowned.

The most important foraminifer in the studied material is *Pseudolituonella reicheli*, which has a short range and is considered to be of mid-late Cenomanian age.

Schroeder and Neumann (1985) indicated that *P. reicheli* is a species mainly of Cenomanian and possibly Turonian age; however Saint-Marc (1974)

assigned the taxon a long stratigraphic range spanning from the mid-Albian to Turonian in Lebanon. In Italy, Luperto-Sinni (1966) assigned a late Cenomanian age to *P. reicheli*; Sartoni and Crescenti (1962) also found the species at the top of the Cenomanian (*Cisalveolina fraasi* Zone). Chiocchini *et al.* (1979, 1984) stated that this foraminifer is limited to the upper Cenomanian rocks; this author used *P. reicheli* as a zonal marker. In France, *P. reicheli* is reported from the Cenomanian in W Aquitaine (Neumann 1962, 1965; Saint-Marc, 1966). Bilotte (1984) considered this species typical of the Cenomanian. Husinec *et al.* (2000) in Croatia and Decrouez (1977) in Greece reported *P. reicheli* from the mid-late Cenomanian. In Israel, it is recorded in the late Cenomanian and Turonian (Reiss, 1957). In Iran, Bozorgnia and Banafti (1964), and Sompó (1969) recorded this species in the Cenomanian. Schulze *et al.* (2004) indicated that *P. reicheli* only occurs in the Cenomanian in west central Jordan. In Turkey, Sari *et al.* (2009) used this microfossil as a late Cenomanian zonal marker. Recently, Frijia *et al.* (2015, p. 129) indicated that this species disappears at levels that can be correlated by carbon isotope stratigraphy to latest Cenomanian (*Neocardioceras juddi* ammonite zone); however, in the studied material we recorded the complete flooding of the platform in this time with deposits of opportunist planktic foraminifers and pithonellids (*Whiteinella archaeocretacea* Zone). In Mexico, Aguilera-Franco (2003) situated *Pseudolituonella reicheli* in the *Pseudorhapydionina dubia* Zone in the Guerrero–Morelos Platform in upper middle-upper Cenomanian. In the Chiapas region, Michaud (1987) regarded this species as middle-late Cenomanian.

Another important species found in the material examined is *Daxia cenomana*, which determines a mid-late Cenomanian age. This species was described by Cuvillier and Szakall (1949) from Audignon in France; they indicated that this genus appears to be restricted to the Cenomanian. It is considered a mid-Cenomanian species by Neumann (1965) and Moreau (1996) in the Charente Maritime region. In Spain, Barroso (2004) found

Daxia cenomana from the Burgos Province, dating it as mid-Cenomanian. Gräfe (2005) recorded *D. cenomana* in the Cenomanian and Turonian from the Basque–Cantabrian Basin. Caus *et al.* (2009) regarded this species as early–mid Cenomanian age in the Iberian Range. Ismail *et al.* (2009) document the occurrence of *D. cenomana* from the Cenomanian in Egypt.

Another form identified in the examined samples is *Merlingina cretacea*, which confirms the mid-late Cenomanian age. It was described from Negev, Israel by Hamaoui and Saint-Marc (1970) as from the Cenomanian. Schroeder and Neumann (1985) regarded the species as restricted to the middle part of the Cenomanian and the base of the Turonian. Caus *et al.* (2009) found this species in mid-upper Cenomanian rocks in the Iberian Peninsula.

Other conspicuous form in the studied samples is *Hemicyclammina sigali*, which is also considered mid-late Cenomanian, taking into account that it is associated with *Pseudolituonella reicheli*.

Hemicyclammina sigali was described for the first time by Maync (1953). He assigned it to the middle Cenomanian age. Berthou (1984a) recorded the occurrence of *H. sigali* restricted to the Cenomanian in the western Portuguese Basin. Later, Hart *et al.* (2005) studied a carbonate succession to outcrops along the valley of the Rio Mondego in the Lusitanian Basin, they stated that *H. sigali* is a particularly useful Cenomanian marker in many Tethyan areas. Bignot and Poisson (1974) recorded this species in the Cenomanian in the Katran, Dağ area, Turkey. Shirazi (2009) documented the presence of *H. sigali* in Iran in the mid-late Cenomanian. It has also been recorded in Syria (Mouty *et al.*, 2003). Berthou and Bengtson (2007) considered *H. sigali* to be a reliable Cenomanian marker from the Sergipe Basin in Brazil.

An abundant form in the studied samples is *Dicyclina schlumbergeri* Munier-Chalmas (1887), associated with the mid-late Cenomanian species.

In Mexico, *D. schlumbergeri* is very common in Albian and Cenomanian strata; it has been reported from east of the VSLPP (Bonet, 1956; Tavitás *et al.*, 1984) as well as in the Morelos Formation in the

Guerrero–Morelos Platform (Aguilera-Franco and Allison, 2005), and in the Sierra Madre Formation in the Chiapas Range (Michaud, 1987). This species has been found in the Orizaba Formation in the Veracruz Basin (Sohl *et al.*, 1991) and the Tepalcatepec Formation in Jalisco and Colima (Ponce de León, 1983; Ornelas, 1984).

The usual occurrence of *Pseudonummoloculina heimi* was recorded in the material examined. The species was described by Bonet (1956) for the first time from the El Abra Canyon in the VSLPP. He assigned it an Albion/Cenomanian age. In Mexico, this species has a similar geographical and stratigraphical distribution to that of *Dicyclina schlumbergeri*. The species is recorded in Texas, Florida, and Louisiana in USA (Conkin and Conkin, 1958). It has also been recorded in Italy (Luperto-Sinni 1966 and Spalluto, 2012), in Slovenia by Koch *et al.* (1998), and in Croatia by Husinec *et al.* (2000); it is also registered in Turkey (Sari *et al.*, 2009) and Syria (Ghanem *et al.*, 2012) in middle–upper Cenomanian strata.

A common species found in the analyzed samples is *Cuneolina pavonia* d'Orbigny. This species is known from Albion to Cenomanian in Tethys strata (Arnaud-Vanneau and Premoli-Silva, 1995). *Peneroplis parvus* is a common species in the samples analyzed. According to Schroeder and Neumann (1985), this form ranges from the latest Albion to mid–Cenomanian. According to Fleury (1980) this species is late Albion to early Cenomanian age from the Varassova Mountains in Greece. In Croatia, *P. parvus* was determined to be in the late Cenomanian (Velić and Vlahović, 1994).

We assigned a mid–late Cenomanian age to *Peneroplis parvus* in the material studied and thus its stratigraphic distribution could be extended from that given in other publications, in which the species is considered as mid–Cenomanian age (De Castro, 1965; Schroeder and Neumann, 1985).

The extinction of all the benthic foraminifera occurred in the Cenomanian/Turonian boundary interval by eutrophication of shallow marine environments and the terrigenous supply, as has been recognized in our material.

The El Abra Cenomanian shallow-water carbonates are overlain by the hemipelagic Soyatal Formation with a *Pithonella* acme and the *r* and *r-k* strategist planktic foraminifera *Muricohedbergella delrioensis*, *M. planispira*, *Heterohelix moremani*, *H. reussi*, *Whiteinella archaeocretacea*, *W. aprica*, *W. brittonensis*, *W. baltica*, *W. paradubia*, *W. prae-helvetica*, and other small benthic foraminifera; for example, *Lingulogavellinella*, *Gavellinella* and textularids. This interval is recognized as the *Whiteinella archaeocretacea* Partial Range Zone, which has been regarded as latest Cenomanian/earliest Turonian, which is important because it constrains the age assigned to the El Abra Limestone.

4.3. PALEOECOLOGY AND PALEOENVIRONMENT

In modern environments, benthic foraminiferal distribution patterns are controlled by temperature, light intensity, nutrient content, substrate, and hydrodynamic energy. It is inferred that they had a similar distribution in the Mesozoic and Cenozoic (Hohenegger, 2000, 2004; BouDagher-Fadel, 2008).

The larger symbiotic-bearing foraminifera are indicative of warm waters (Murray, 1991). Their depth distribution is related to light, which is the main factor because it is required by the symbionts. The influence of the symbionts on the shape of the foraminiferal test as well as the hydrodynamic factor provides an important tool for paleoenvironmental interpretation. Thus, detached life forms with robust spherical tests indicate current-swept reef environments while thin fragile tests with maximum surface-to-volume ratios will be found in quiet low-light environments (Haynes, 1965). This is supported by the modern assemblage study. Recent larger foraminifera may occur as encrusters, periphyton (free-living on seagrass and calcareous algae), or living on or in the sediment (epifaunal, infaunal). In higher energy environments, encrusters and periphyton are the most common, while algal-film and sediment dwellers predominate under lower energy conditions (Hallock and Glenn, 1986; Murray, 2006).

Recent *Peneroplis* and *Spiroloculina* are known as epiphytic forms (Langer, 1993) or living in sea grass (Hallock and Glenn, 1986).

In this study, benthic foraminifera, together with other biogenic components such as algae, as well as lithologic characteristics were used to reconstruct the paleoenvironmental conditions that existed during the El Abra deposit.

The El Abra Formation (Taninul Facies) in the studied successions, Llanos del Carmen, Cerritos and El Temazcal sections, is characterized by an abundant and diversified benthic foraminiferal assemblage, composed of *Pseudolituonella reicheli*, *Hemicyclammina sigali*, *Daxia cenomana*, *Merlingina cretacea*, *Cuneolina pavonia*, *Cuneolina pavonia parva*, *Pseudocyclammina sp.*, *Dicyclina schlumbergeri*, *Nezzazatina gyra*, *N. simplex*, *Nezzazatinella picardi*, and *Peneroplis parvus*. The algae recorded are *Bouenia pygmaea* and *Neomeris cretacea*, as well as the encrusters *Lithocodium aggregatum* and *Thaumatoporella parvovesiculifera*.

The great variety and diversity of the benthic foraminifers, together with algae and invertebrates such as rudists, gastropods, echinoderms, and calcareous worm tubes, as well as the peloidal bioclastic packstone–grainstone texture of the rock, suggest a shallow-water environment within the euphotic zone on the open marine platform during stable salinity and temperature conditions, permitting this oligotrophic association to develop and flourish. The occurrence of large-sized discoidal and conical benthic foraminifers such as *Dicyclina*, *Cuneolina*, and the encrusting habit of *Thaumatoporella parvovesiculifera* and *Lithocodium*, indicate medium hydrodynamic energy.

There is a conspicuous change in the top of the El Abra Formation. The foraminiferal community is reduced to a few benthic foraminifers such as *Nezzazatinella picardi*, miliolids, and rotalids, and the algae *Permocalculus irenae* and *P. budaensis*. The abundance of algae as well as decreased diversity of benthic foraminifera indicates a marine deposit associated with changes in the nutrient supply to the platform that caused the larger sized foraminifers adapted to oligotrophic conditions to disappear, reducing the assemblage to small forms, indicating a decrease of benthic-factory carbonate

production (Schlager, 1981), which preceded the drowning of the platform. The Soyatal Formation overlies the El Abra limestone, which consists of a foraminiferal packstone–wackestone with an overabundance of pithonellids, *r* and *r-k* strategist planktic, and different benthic foraminifers such as gavellinelids, which indicate a deeper and eutrophic environment. These significant faunal and lithological changes are related to an early phase of the transgression that flooded the VSLPP in the latest Cenomanian (*Whiteinella archaeocretacea* Partial Range Zone).

A lateral change of facies of the El Abra Formation, termed the El Abra facies, is recorded in the La Minita outcrop, which is characterized by a cream limestone represented by a wackestone with abundant miliolids and ostreids adapted to survive within environments with varying salinities, these characteristics suggest a restricted shallow environment. Other microfacies is identified showing a larger diversity of species including *Pseudonummoloculina heimi* and *Ovalveolina maccagnoae*, other alveolinids, *Dicyclina schlumbergeri* and *Cuneolina pavonia* allow us to infer an intermediate semi-restricted shallow-water environment.

4.4. SYSTEMATIC PALEONTOLOGY

The benthic foraminifers contained in the limestone samples of the El Abra Formation are abundant and well preserved. The new suprageneric agglutinated foraminiferal assignment is based on the classification proposed by Kaminski (2014) for the agglutinated foraminifera, and Pawlowski *et al.* (2013 partim).

The thin sections are housed in the Paleontology Collection of the Institute of Geology (Universidad Nacional Autónoma de México).

Class FORAMINIFERA d'Orbigny, 1826
Subclass Globothalamea Pawlowski Holzmann
and Tyszk, 2013
Order Lituolida Lankester, 1885
Suborder Nezzazatina Kaminski, 2004
Superfamily Nezzazatoidea Hamaoui and Saint-Marc, 1970

Figure 8 Mid-late Cenomanian foraminifera from the El Abra Formation (scale bar 200 μ m). a: *Biconcava bentori* tangential section; b: *Charentia* sp. equatorial section (Sample G-2) (Sample LLC-1); c: *Daxia cenomana* equatorial section (Sample LLC-1); d: *Pseudocyclammina* sp. subaxial section (Sample LLC-2).

Family Nautiloculinidae Loeblich and Tappan,
1985

Genus *Biconcava* Hamaoui, 1965

Type species. *Biconcava bentori* Hamaoui, 1965

Biconcava bentori Hamaoui, 1965

(Figure 8a)

Biconcava bentori Hamaoui 1965, p. 14; Hamaoui and Saint-Marc, 1970, p. 304, pl. 18–21; Loeblich and Tappan, 1988, p. 71, pl. 55, figs. 1–4.

Description: Test planispirally coiled with three whorls, showing a rounded proloculus, the cham-

bers growing slowly; curved sutures, but slightly curved in. The last whorl has 18 chambers.

Remarks: Loeblich and Tappan (1988) transferred *Biconcava* to Maycinidae due the absence of a rudimentary internal tooth plate described by Hamaoui and Saint-Marc (1970, p. 301). The former authors stated, “this genus is closest in appearance to *Daxia* but differs in being more evolute and in the aperture located in a vertical groove in the apertural face.”

Genus *Daxia* Cuvillier and Szakall, 1949

Type species: *Daxia cenomana* Cuvillier and Szakall, 1949

Daxia cenomana Cuvillier and Szakall, 1949

(Figure 8c, 9a)

Daxia cenomana Cuvillier and Szakall, 1949, p. 8, pl. 2, figs. 4–6; Maync, 1952, p. 55, pl. 11, fig. 3; Schroeder and Neumann, 1985, p. 15, pl. 1, figs. 1–8.1.

Description: Test planispirally coiled; with a rounded proloculus followed by rhomboid-shaped chambers; the latest chambers are low and elongated with curved sutures. Some specimens in our material possess 12–16 chambers in the last whorl. The measured height varies from 500 to 700 µm; the diameter of the proloculus is 30 µm.

Remarks: *Daxia cenomana* differs from *Daxia minima* Laug and Peybernès (1979) of the Aptian (Pyrénées Basco-Béarnaises), in its larger size, thinner septa and sutures less depressed in equatorial section.

Occurrence: *Daxia cenomana* is considered a typical Tethysian species (Schroeder and Neumann, 1985), and has been recorded in France (Cuvillier and Szakall, 1949; Neumann, 1965; Bilotte, 1984), Spain (Calonge and Caus, 1996; Gräfe, 2005; Barroso, 2004; Caus *et al.*, 2009), Portugal (Berthou, 1984b; Berthou and Lauverjat, 1979), and Egypt (Ismail *et al.*, 2009; Anan *et al.*, 2013).

VSLPP, it was recorded in the Llanos del Carmen, Cerritos, and Temazcal sections.

Family Nezzazatidae Hamaoui and Saint-Marc, 1970

Subfamily Nezzazatinae Hamaoui and Saint-Marc, 1970

Genus *Merlingina* Hamaoui, 1965

Type species: *Merlingina cretacea* Hamaoui, 1965

Merlingina cretacea Hamaoui, 1965

(Figure 9c)

Merlingina cretacea Hamaoui, 1965, p. 7, pl. 9, fig. 6; pl. 14, fig. 14; Hamaoui and Saint-Marc, 1970, p. 315, pl. 22–27; Schroeder and Neumann, 1985, pl. 1, figs. 1–8, p. 37, pl. 15, figs. 1–9; Michaud, 1987, pl. 12, figs. 1–12.

Description: The specimen illustrated is a triangular section with initial part planispiral, later uncoiled and finally flaring; broad and low cham-

bers, subdivided by tooth plate slightly curved inward from the lateral borders of the apertural face, having two or three basal digitations attaching to the septum of the preceding chamber; sutures sinuous.

Remarks: *Merlingina* differs from *Nezzazata* and *Biconcava* by having an uncoiled stage in adult specimens, with rapid enlarging of spire, and sutures more complex as well as the aperture with a more complex tooth plate (Hamaoui and Saint-Marc, 1970).

Occurrence: *Merlingina cretacea* was described from a subsurface sample from Negev, Israel (Hamaoui and Saint-Marc, 1970). It has been recorded in Italy (Chiochini *et al.*, 1984), Spain (Caus *et al.*, 2009), Turkey (Sari *et al.*, 2009), Oman (Philip *et al.*, 1995), and Syria (Ghanem *et al.*, 2012). In the Americas, this species was identified in Mexico from the Chiapas Platform (Michaud, 1987) and the Morelos Guerrero Platform (Aguilera-Franco, 2003), and in Peru (Jaillard and Arnaud-Vanneau, 1993).

VSLPP in the Llanos del Carmen section.

Genus *Nezzazata* Omara, 1956

Type species: *Nezzazata simplex* Omara, 1956

Nezzazata simplex Omara, 1956

(Figure 9f and 9g)

Nezzazata simplex Omara, 1956, p. 887, pl. 102, figs. 7–13; Hamaoui and Saint-Marc, 1970, p. 348, pl. 40 fig. 13; Schroeder and Neumann, 1985, p. 33, pl. 11, figs. 1–11; Ettachfini and Andreu, 2004, p. 286, figs 8 b, c.

Description: Test sub-circular, trochospiral, ventral side convex, dorsal area moderately convex; the chambers increasing slightly in size as added; ventral sutures radial, slightly depressed with a small indentation in the septal suture, which points backwards away from the apertural face, umbilical area closed. The aperture extending from near the umbilical region at the base of the apertural face bending below the dorsal wall parallel to the periphery; the bend nearly forms an L-shaped orifice, with a flattened tooth-like outgrowth (Loeblich and Tappan, 1988, p. 83).

Figure 9 Mid-late Cenomanian foraminifera from the El Abra Formation (All scale bars 200 µm except f, g scale bar 500 µm. a: *Daxia cenomana* equatorial section (Sample ET-4); b: *Nezzazatinella picardi* equatorial section on the spiral and the umbilical side (Sample ET-4); c: *Merlingina cretacea* oblique section (Sample LLC-5); d: *Nezzazata gyra* oblique subequatorial section (Sample ET-4); e: *Hemicyclammina sigali* equatorial section (Sample LLC-1); f, g: *Nezzazata simplex* equatorial section on spiral and umbilical side (Sample LLC-1).

Remarks: *Nezzazata conica* (Smout, 1956) differs from *N. simplex* by possessing a very convex umbilical side and a smaller umbilicus. *N. simplex* differs from *N. convexa* (Smout, 1956) by possessing a flat to slightly convex spiral side rather than a strongly convex planispiral side; and is distinct from *N. concava* (Smout, 1956) because it has a strongly concave spiral view. Hauterivian *Nezzazata germanica* Omara and Strauch (1965) is poorly described and could be incorrectly assigned to *Nezzazata* because it does not have the tooth plate (Arnaud-Vanneau and Sliter, 1995).

Occurrence: *Nezzazata simplex* was recorded in the lower part of the Cenomanian of Gebel Nezzazat, west central Sinai by Omara (1956). Omara and Strauch (1965) extended the stratigraphic range to the early Turonian. Ismail *et al.* (2009) recorded it in the late Cenomanian. This species has been recorded from the Cenomanian in Italy (Simone *et al.*, 2012), Croatia (Husinec *et al.*, 2000), and Turkey (Sari *et al.*, 2009); Syria (Ghanem *et al.*, 2012). In Mexico, it has been found in the Chiapas Platform (Michaud, 1987) and the Guerrero Platform (Aguilera-Franco, 2003). It has also been found in Honduras by Scott and Finch (1999). VSLPP in the Llano del Carmen and Guadalcázar sections.

Nezzazata gyra (Smout, 1956)

(Figure 9d)

Beggia gr. *gyra* Smout, 1956, p. 340, pl. 1, figs. 1–9; *Nezzazata gyra* (Smout) Schroeder and Neumann, 1985, p. 34, pl. 12, fig. 9.

Description: Test plano-convex with three whorls on the spiral side; umbilicus closed, chambers with a narrow internal plate extending back from one septum to the previous septum resulting in a kink or indentation in the septal suture, typical aperture with an apertural tooth.

Remarks: *Nezzazata gyra* differs from *N. simplex* by possessing a false umbilicus and from the Aptian–early Albian *N. isabellae* (Arnaud-Vanneau and Sliter, 1995) by having larger size and a well-developed tooth plate which extends to the previous aperture.

Occurrence: *Nezzazata gyra* has been reported from the Cenomanian in Italy (Luperto-Sinni, 1966), southern Croatia (Husinec *et al.*, 2009), Syria (Ghanem *et al.*, 2012), Egypt (Ismail *et al.*, 2009), the subsurface of Iraq (Bernaus and Masse, 2006), and Turkey (Farinacci and Yeniay, 1986). VSLPP in the Llano del Carmen, Guadalcázar and Cerritos sections.

Genus *Nezzatinella* Darmoian, 1976

Type species: *Nezzazinella adhami* Darmoian, 1976, p. 492

Nezzazinella picardi (Henson, 1948a)

(Figure 9b)

Valvulamina picardi Henson, 1948a, p. 613, pl. 15, figs. 1, 3, pl. 18, figs. 3–6; *Nezzazinella picardi* (Henson) Aguilera-Franco *et al.*, 2001, p. 248, fig. 9 i; Sari *et al.*, 2009, p. 60, pl. 2, figs. 12, 13; Rahimpour-Bonab *et al.*, 2012, p. 28, fig. 8 p.

Description: Test trochospiral, dorsal side flat or slightly convex; with chambers arranged in 1–2 whorls; they are narrow, elongated, with the last chamber flaring backwards, 11 chambers in the last whorl, sutures radial, depressed; the apertural area is wide with a large curved slit, may have secondary apertures in a curved row or scattered over the umbilicus region (Henson, 1948a; Loeblich and Tappan, 1988).

Remarks: *Nezzazinella picardi* differs from pre-Coniacian *N. adhami* Darmoian (1976) by having fewer and differently shaped chambers and a larger aperture with secondary apertures in a curved row or scattered over the apertural face. This species differs from Turonian *N. aegyptiaca* (Said and Kenawy, 1957) by having more chambers in the last whorl, and more depressed sutures in the umbilical side.

Nezzazinella picardi is distinguished from Barremian/Aptian *N. macovei* Neagu (1979) by possessing a smaller test, a rounded periphery, chambers less elongated, and radial sutures in the umbilical side in place of a test in later species that measures more than 1 mm, with a lobate and angled margin, and strongly curved sutures in the umbilical view.

Occurrence: *N. picardi* occurs widely in Upper Cretaceous rocks. This species was described for the first time as *Valvulammina picardi* from the Santonian beds of Egypt (Henson, 1948a). Forms comparable to it were later described and drawn from the Albian and Cenomanian of Israel, Lebanon, Iran, Slovenia, Croatia, Turkey, and Portugal (Reiss, 1961; Bozorgnia and Banafti, 1964; Dozet and Šribar, 1998; Hamaoui, 1966; Hamaoui and Saint-Marc, 1970; Moro and Jelaska, 1994; Koch *et al.*, 1998; Sari *et al.*, 2009; Berthou and Lauvejat, 1979).

VSLPP in the Llanos del Carmen, Cerritos, and Temazcal sections.

Order Loftusiida Kaminski and Mikhalevich, in Kaminski, 2004

Suborder Loftusiina Kaminski and Mikhalevich, in Kaminski, 2004

Family Cyclamminidae Marie, 1941

Subfamily Hemicyclammininae Banner, 1966

Genus *Hemicyclammina* Maync, 1953

Type species: *Hemicyclammina sigali* Maync, 1953

Hemicyclammina sigali Maync, 1953

(Figure 9e)

Hemicyclammina sigali Maync, 1953, p. 148, figs. 1–5; Saint-Marc, 1970, p. 232, pl. 3, figs. 4, 5; Shirazi *et al.*, 2011, p. 783, pl. 2, fig. 11.

Description: Test planispiral, shows a rounded to subacute periphery, with a small proloculus, and a last chamber incompletely subdivided by a discontinuous straight or slightly curved septum; wall agglutinated, outer layer imperforate, and sub-epidermal layer uniformly alveolar; the lower part of the septa coalesces as an imperforate basal layer against the previous whorl, in equatorial section appearing very short and originally termed semi-septa (Maync, 1953; Loeblich and Tappan, 1988).

Remarks: *Hemicyclammina sigali* differs from Albian *H. whitei* (Henson, 1948b) because the latter species possesses the septa in contact with the test periphery at right angles to form chambers that are almost quadrangular (in equatorial section). In axial section *H. sigali* is more compressed.

The Coniacian/Santonian *Hemicyclammina chalmasi* (Schlumberger, 1899) differs from *H. sigali* by having a thick and coarsely agglutinated wall and large test with chambers increasing in height, producing a peneropliform test.

Occurrence: *Hemicyclammina sigali* was described by Maync (1953) from the middle Cenomanian of the Constantine Province in Algeria. This species is recorded in Portugal by Hart *et al.* (2005), Italy (Simone *et al.*, 2012), Turkey (Bignot and Poisson, 1974), Iran (Shirazi, 2009), Syria (Mouty *et al.*, 2003), Jordan (Weidich and Al-Harithi, 1990), and Brazil (Berthou and Bengtson, 2007).

VSLPP in the Llanos del Carmen

Subfamily Choffatellinae Maync, 1958

Genus *Pseudocyclammina* Yabe and Hanzawa, 1926

Type species: *Cyclammina lituus* Yokohama, 1890

Pseudocyclammina sp.

(Figure 8d)

Description: Test planispiral with a rounded periphery; composed of three whorled chambers growing rapidly; sutures oblique, wall coarsely agglutinated with a thick subepidermal network with numerous alveoles closely spaced in the agglutinated wall and septa (Loeblich and Tappan, 1988).

Occurrence: VSLPP in the Llanos del Carmen, Cerritos, El Temazcal sections.

Suborder Biokovinina Kaminski, 2004

Superfamily Biokovinacea Gusić, 1977

Family Charentididae Loeblich and Tappan, 1985

Genus *Charentia* Neumann, 1965

Type species: *Charentia cuwillieri* Neumann, 1965

Charentia sp.

(Figure 8b)

Description: Test planispiral later partly uncoiled with ten chambers in last whorl; the periphery is rounded; imperforate wall pierced by cylindrical canaliculi resembling keriotheca or pseudoalveolar structure; wall of the early chambers and apertural surface solid, noncanaliculate;

the portion of the apertural surface beneath the aperture distinctly thickened to form a triangular chomata-like projection.

Remarks: *Charentia* sp. differs from *Charentia cuvillieri* Neumann (1965) by having fewer whorls and chambers.

Occurrence: VSLPP in the El Temazcal section.

Suborder Ataxophragmioidea Schwager, 1877

Superfamily Ataxophragmiacea Schwager, 1877

Family Cuneolinidae Saidova, 1981

Subfamily Cuneolininae Saidova, 1981

Genus *Cuneolina* d'Orbigny, 1839

Type species: *Cuneolina pavonia* d'Orbigny, 1846

Cuneolina pavonia d'Orbigny, 1846

(Figure 10a and 10b)

Cuneolina pavonia d'Orbigny, 1846, p. 253, pl. 21, figs. 50–52; Chiocchini *et al.*, 1984 p. 181, pl. 5, fig. 1; Tasli *et al.*, 2006, p. 529, fig. 6 L; Sari *et al.*, 2009, p. 423, pl. 3–7.

Description: Test compressed conical to flabelliform, early trochospire followed by very broad, low biserially arranged chambers, commonly compressed parallel to the plane of biseriality; interior subdivided into nearly rectangular chamberlets by radial partitions positioned perpendicular to the outer wall and projecting inward toward the plane of biseriality, and by horizontal partitions paralleling the septa; wall agglutinated, imperforate, with reticulate subepidermal layer (cf. Loeblich and Tappan, 1988, p. 48).

Remarks: The two species reported most often are *Cuneolina pavonia* d'Orbigny and *C. parva* Henson. *C. pavonia* is flabelliform and tends to be slightly larger and have a greater apical angle than *C. parva*, which is conical and elongate (Arnaud-Vanneau and Sliter, 1995; Arnaud-Vanneau and Premoli-Silva, 1995).

Cuneolina pavonia d'Orbigny (1846) differs from Santonian *Cuneolina conica* d'Orbigny (1850) by having a broader test. *C. pavonia* differs from Aptian/Albian *Cuneolina sliteri* Arnaud-Vanneau and Sliter (1995) by having a larger size and flabel-

liform test instead of a triangular test with a short biserial stage with 6 or 7 chambers in later species.

Occurrence: VSLPP in the Llanos del Carmen, Cerritos, Temazcal sections.

Cuneolina parva Henson, 1948a

(Figure 10c to 10f)

Cuneolina pavonia parva Henson, 1948a, p. 624–627, pl. 14, figs. 1–6, pl. 17, figs. 7–12, pl. 18 figs. 12–14; *Cuneolina parva* Arnaud-Vanneau and Sliter, 1995, pl. 4, figs. 6–9; Filkorn and Scott, 2011, p. 184, figs. 4, 11–12.

Description: Test compressed, conical. Embryonic apparatus composed of a large, oval protoconch covered by a deuteroconch followed by a broad, low biserial stage. Chambers compressed parallel to the plane of biseriality and subdivided by radial beams, and one or two transverse rafters that produce a subepidermal rectangular network.

Remarks: *Cuneolina parva* was described by Henson (1948a) from the Santonian of Egypt. This species differs from *C. pavonia* d'Orbigny (1846) by possessing a smaller test with a large megasphere and smaller biserial stage as well as having a smaller apical angle than *C. pavonia* has two to three transverse rafters in the chambers compared to one to two in *C. parva* (Arnaud-Vanneau and Sliter, 1995; Arnaud-Vanneau and Premoli-Silva, 1995). *Cuneolina parva* is reported from Albian–Cenomanian strata and *C. pavonia* from uppermost Albian to Santonian (Filkorn and Scott, 2011).

C. parva differs from Barremian/Aptian *C. hensoni* Dalbiez (1958) by having a dense network of radial partitions and more common occurrence of transverse rafters. *C. parva* is similar in cross section to the Maastrichtian Iraquian *C. cylindrica* Henson (1948a). The latter possesses a remarkable triangular test and almost cylindrical early stage.

Occurrence: The species is mostly known from the southern margin of the Tethys in the Middle East, Egypt, Greece, Italy, Albania, Yugoslavia, and North Africa, and from the northern margin in France and Spain (Arnaud-Vanneau and Premoli-Silva, 1995), and in Mexico: as *Cuneolina*

Figure 10 Mid-late Cenomanian foraminifera from the El Abra Formation. a: *Cuneolina pavonia* axial section (Sample G-5); b: *Cuneolina pavonia* axial section (Sample ET-1); c: *Cuneolina parva* axial section (Sample LLC-5); d: *Cuneolina parva* axial section (Sample ET-1); e: *Cuneolina parva* axial section (Sample LLC-5); f: *Cuneolina parva* axial section (Sample LLC-5); g: *Dicyclina schlumbergeri* axial section equatorial section showing the great proloculus (Sample G-5); h: *Dicyclina schlumbergeri* axial section (Sample LLC-5); i: *Dicyclina schlumbergeri* axial section subequatorial section (Sample LLC-2); j: *Dicyclina schlumbergeri* subaxial section (Sample G-5).

walteri (in Scott and González-León 1991, p. 58; Filkorn and Scott, 2011); in Florida from subsurface samples (Cushman and Applin, 1947).

VSLPP in the Llanos del Carmen, Cerritos, Guadalcázar, and the El Temazcal sections.

Family Dicyclinidae Loeblich and Tappan, 1964

Genus *Dicyclina* Munier-Chalmas, 1887

Type species *Dicyclina schlumbergeri* Munier
Chalmas, 1887

Dicyclina schlumbergeri Munier Chalmas, 1887
(Figures 10g to 10j)

1887 *Dicyclina schlumbergeri* Munier Chalmas, p. xxx-xxxi; Schlumberger and Choffat, 1904, p. 362, fig. 1, p. 363, fig. 2; Bonet, 1956, p. 406, pls. 5–7; Sari *et al.*, 2009, p. 61, pl. 3, figs. 8, 9.

Description: Test discoidal, flattened, slightly undulating, initial stage slightly inflated; the megalospheric generation consists solely of the proloculus measuring 700 µm. Later annular chambers added alternating on either side of the test, interior subdivided by numerous thin radial partitions, perpendicular to the outer wall and aligned from chamber to chamber. Wall agglutinated with an imperforate epidermis. The exoskeleton comprises beams and rafters organized in a subepidermic network (Loeblich and Tappan, 1988).

Remarks: Cherchi and Schroeder (1990) stated that *Dicyclina* was until recently assigned solely to *Dicyclina schlumbergeri*, a taxon ranging from the late Albian to Maastrichtian (Bilotte, 1984); however, these authors showed that *Dicyclina* comprises at least two species the mid-Cenomanian *D. simplex* and the Coniacian/Santonian *D. schlumbergeri*. These taxa were differentiated based on the different degree of development of the embryonic megalospheric apparatus. We assigned our specimens to *D. schlumbergeri*, which we consider to be valid because the Mexican specimens have a large, complex embryo (Figure 10g). *D. schlumbergeri* differs from the Iranian Cenomanian *D. sampoi* by not having a special layer of the secondary chamberlets in the uppermost part of the supraembryonic

zone and the lowermost part of subembryonic zone (Cherchi and Schroeder, 1990).

Occurrence: *D. schlumbergeri* is widely distributed in the Tethys; it has been reported in Italy (Cherchi *et al.*, 2008), Portugal (Berhou and Lauverjat, 1979), Slovenia (Koch *et al.*, 1998), Spain (Ullastre and Masrera, 2006), the Vardar region, Macedonia (Polavder, 2003), Turkey (Farinacci and Yeniyay, 1986; Tasli, 2006; Robertson, *et al.*, 2013), Iran (Afghah *et al.*, 2014), and Morocco (Ettachfini *et al.*, 2005; Lézin *et al.*, 2012).

VSLPP in the Llanos del Carmen, Cerritos, Guadalcázar, and El Temazcal sections.

Suborder Orbitolinina Kaminski, 2004

Superfamily Coskinolinoidea Moullade, 1965

Family Coskinolinidae Moullade, 1965

Genus *Pseudolituonella* Marie, 1954

Type species: *Pseudolituonella reicheli* Marie, 1954

Pseudolituonella reicheli Marie, 1954
(Figure 11a)

Pseudolituonella reicheli Marie 1954, p. 117–119, text-fig. 2a–b; Luperto-Sinni, 1966, p. 149, pl. 10, fig. 1; Chiochini *et al.*, 1984, p. 181, pl. 5, fig. 15; Schroeder and Neumann, 1985, p. 27, pl. 8, figs. 1–9; Michaud, 1987, pl. 11, fig. 2; Loeblich and Tappan, 1988, p. 155, pl. 166, figs. 7–11; Aguilera-Franco *et al.*, 2001, p. 248, fig. 9d; Sari *et al.*, 2009, p. 61, pl. 3, fig. 10.

Description: Follows Loeblich and Tappan (1988, p. 155): Test elongate, conical, early portion with a short trochospiral stage, later with broad, low uniserial chambers divided by depressed sutures; interior chamber with tubular pillars projecting upward from the margins of the circular apertures but not completely crossing the chambers; wall microgranular, imperforate. The aperture is cribrate with numerous pores in the center of the apertural face.

Remarks: *Pseudolituonella reicheli* differs from lower Aptian *P. conica* Luperto-Sinni and Masse (1993) because the latter species has the initial trochospiral stage in an eccentric position, and a thinner wall.

Figure 11 Mid-late Cenomanian foraminifera from the El Abra Formation (all scale bars 200 μ m). a: *Pseudolituonellareicheli* axial section (Sample LLC-1); b: *Minouxia inflata* axial section (Sample G-1); c: *Peneroplis parvus* axial section (Sample ET-1); d: *Archaeocyclus cenomanianus* (Sample LLC-5); e: *Ovalveolina maccagnoae* equatorial section (Sample LM-5); f: *Pseudonummoloculina heimi* subequatorial section (Sample LM-5); g: *Spiroloculina cenomana* axial section (Sample C-3); h: *Ovalveolina maccagnoae* subaxial section (Sample LM-5).

Barremian *Pseudolituonella gavonensis* Foury (1968) is different from *P. reicheli* by having a streptospiral early stage. *P. reicheli* differs from upper Santonian *P. mariae* Gendrot (1968) by having a larger test and reduced trochospiral stage, and more developed uniserial stage compared to the latter species, possessing only two or three chambers in the uniserial portion.

Occurrence: *Pseudolituonella reicheli* is a typical Tethysian species. Its geographical and stratigraphical distribution has already been discussed above.

VSLPP in the Llanos del Carmen and Cerritos sections.

Order Textulariida Delage and Hérouard 1896,
emended Kaminski, 2004

Superfamily Eggerelloidea Cushman, 1937

Family Eggerellidae Cushman, 1937

Subfamily Minouxinae Loeblich and Tappan,
1986

Genre *Minouxia* Marie, 1954

Type species: *Minouxia guembeltrioides* Marie,
1954, p. 119

Minouxia inflata Tronchetti and Zijlstra-Bessais,
2002

(Figure 11b)

Minouxia inflata Tronchetti and Zijlstra-Bessais,
2002, p. 541, pl. 1; figs. 1–7; pl. 2, figs. 1–8; pl. 3,
figs. 1–4; pl. 4, figs. 3–5

Description: Test conical, elongate, triserial with globular and inflated chambers, the last chamber larger, sutures depressed; wall thin, agglutinated, finely canaliculate, aperture multiple that consists in circular openings in the latest chamber on a trematophore-like plate that covers the umbilical region (Loeblich and Tappan, 1988; Tronchetti and Zijlstra-Bessais, 2002).

Remarks: *Minouxia inflata* was described from Cenomanian beds of central Tunisia by Tronchetti and Zijlstra-Bessais (2002).

Minouxia differs from *Tetraminouxia* by having a triserial arrangement instead of quadriserial cham-

bers arranged throughout as in the latter genus. *Minouxia inflata* is different from Maastrichtian *M. guembeltrioides* Marie (1954) by having fewer chambers, the last chamber covering the preceding chambers.

Minouxia inflata differs from Santonian *M. conica* Gendrot (1963) by having a larger test and globular chambers in place of chambers longer than wide in a conical test.

Minouxia inflata shows globular chambers in axial sections like Santonian *M. lobata* Gendrot (1963).

Occurrence: VSLPP in the Llanos del Carmen, Cerritos, Guadalucazar, and Temazcal sections.

Subclass Tubothalamea Pawlowski, Holzmann,
Tyszk, 2013

Order Miliolida Delage and Hérouard, 1896

Superfamily Miliolacea Ehrenberg, 1839

Family Spiroloculinidae Wiesner, 1920

Genus *Spiroloculina* d'Orbigny, 1826

Type species: *Spiroloculina depressa* d'Orbigny,
1826

Spiroloculina cenomana Chiocchini, 2008

(Figure 11g)

Spiroloculina cenomana Chiocchini, 2008, p. 187, pl.
II, fig. 1.

Description: Test elliptical in outline, with strongly carinate extremities; last chambers changing plane of coiling and showing a sigmoid arrangement, and truncate periphery; sphaeric proloculus followed by a tubular second chamber one whorl in length, the last part with four pairs of chambers added in a single plane; aperture at open end of the final chamber consists of simple or bifid tooth commonly on a short neck. Wall is calcareous, imperforate, porcelanaceous (Chiocchini, 2008).

Remarks: *Spiroloculina cenomana* differs from *S. cretacea* due to the former having a sigmoidal chamber arrangement and a truncate periphery.

Occurrence: VSLPP in the Llanos del Carmen, Cerritos, Guadalucazar, and the El Temazcal sections.

Family *Hauerenidae* Schwager, 1876

Pseudonummoloculina Calvez, 1988

Type species: *Pseudonummoloculina aurigerica*
Calvez, 1988

Pseudonummoloculina heimi (Bonet, 1956)

(Figure 11f)

Nummuloculina heimi Bonet, 1956, p. 402, pl. 3, 4; Conkin and Conkin, 1958, p. 156, pl. 1, figs. 1–10; Michaud, 1987, p. 268, pl. 3, fig. 15; *Pseudonummoloculina heimi* (Bonet) Scott and González-León, 1991, p. 61, pl. 5L; Sari *et al.*, 2009, p. 62, pl. 4, figs. 6, 7

Description: Test discoidal, streptospirally involute, with a megalosphere provided with a miliolid bottle-neck (goulot) and at least in adult growth stages, with more than two chambers per whorl; wall calcareous porcelanaceous.

Remarks: The genus *Pseudonummoloculina* is represented by four species: *P. aurigerica* Calvez from the early to middle Albian of the Pyrenees, France; *P. heimi* (Bonet, 1956) from the Albian to Cenomanian of Mexico; *P. robusta* (Torre, 1966) from the Senonian of Italy; and *P. irregularis* (Decrouez and Radoičić, 1977) from the Santonian-Campanian of W Serbia. *Pseudonummoloculina heimi* differs from early to middle Albian ovoidal *P. aurigerica* by having a discoidal test and a more reduced early stage but a more developed final stage (Mancinelli and Chiochini, 2006). Senonian *Pseudonummoloculina robusta* differs from *P. heimi* by possessing an inflated test and a very thick wall. The Santonian/Campanian *P. irregularis* differs from *P. heimi* by having more chambers per whorl and a plane of coiling which changes irregularly.

Occurrence: *P. heimi* is widely distributed in the Albian/Cenomanian of the Gulf Coast and other localities from the Mediterranean area.

VSLPP, the La Minita locality.

Superfamily Alveolinacea Ehrenberg, 1839

Family Alveolinidae Ehrenberg, 1839

Ovalveolina Reichel 1936

Type species: *Alveolina ovum* d'Orbigny, 1850

Ovalveolina maccagnoae De Castro, 1966

(Figures 11e to 11h)

Ovalveolina maccagnoae De Castro, 1966; Schroeder and Neumann, 1985, p. 106–109, pl. 50, figs. 5–7.

Description: The test of megalospheric form is planispiral involute, spherical proloculus followed by a flexostyle; the chambers short and numerous; in equatorial section the chamberlets can be elongated, elliptical from the first whorls, later appearing rectangular, preseptal passage elongated occupies a third part of the chamber; in the subaxial section the chamberlets have a pyriform appearance in the last whorl; wall porcelanaceous.

Remarks: The mid-Cretaceous alveolinids are poorly known from the New World but *Streptolveolina mexicana* Fourcade, Tardy and Vila (1974) was described from the Mexican Cenomanian strata (Aurora Formation). This species is considered endemic to the Caribbean Province, but appears to be related to species in the Mediterranean area such as *S. peybernesi* (De Castro, 1983). *Streptolveolina mexicana* has been also recorded in some localities of Gulf Coast in the Albian–Cenomanian (Scott, 2002; Mancini and Scott, 2006). Omaña *et al.* (2012) reported *Ovalveolina maccagnoae* De Castro, 1966 from the Cenomanian deposits of the Manantlan Range in Colima State, Mexico.

Further alveolinids *Selliolveolina* sp. and *S. cf. drorimensis* were reported from the Cenomanian in northern Peru by Jaillard and Arnaud-Vanneau (1993, p. 603).

Occurrence: VSLPP in the La Minita outcrop.

Family Peneroplidae Schultze, 1854

Peneroplis de Montfort, 1808

Type species: *Peneroplis planatus* Fichtel and Moll, 1798, p. 91

Peneroplis parvus De Castro, 1965

(Figure 11c)

Peneroplis parvus De Castro, 1965, p. 345–348, pl. 1, 14–15; Schroeder and Neumann, 1985, p. 86, pl. 39, figs. 1–17; Tasli *et al.*, 2006, p. 529, pl. 6, fig. O.

Description: Test with a rounded proloculus, early stage planispirally coiled, later with or

without uncoiling stage; the chambers quickly increasing in width, resulting in a flaring peneropliform test. Sutures slightly depressed. Wall is calcareous imperforate porcelaneous; the surface with numerous grooves alternating with fine ribs perpendicular to the sutures.

Remarks: *Peneroplis parvus* is like the Recent *P. planatus* but differs by having a smaller size and more numerous chambers. It differs from *P. turonicus* (Said and Kenawy, 1957) because the latter species lacks radial striae on the outside surface. By this character *P. turonicus* could be assigned to *Laevipeneroplis*, according to the foraminiferal generic classification of Loeblich and Tappan (1988).

Peneroplis was placed in the family Soritidae by Schroeder and Neumann (1985); later Loeblich and Tappan (1988) settled it in the family Peneroplidae because this form has chambers with a simple interior, while the family Soritidae has chambers subdivided by interseptal pillars or septula.

Occurrence: *Peneroplis parvus* was described for the first time by De Castro (1966) from the mid-Cenomanian from the Campania region (Italy); this species has been recorded from Spain (Calonge and Caus, 1996), Croatia (Velić and Vlahović, 1994), Turkey (Tasli, 2006), and Syria (Ghanem and Kuss, 2013).

VSLPP in the Llanos del Carmen, Cerritos, Guadalcázar, and Temazcal sections.

Subclass Globothalamea Pawlowski, Holzmann
and Tyszka 2013

Order Rotaliina Delage and Hérourard, 1896

Superfamily Planorbulinacea Schwager, 1877

Family Cymbaloporidae Cushman, 1927

Archaecyclus Silvestri, 1908

Type species: *Planorbulina cenomaniana* Seguenza,
1882

Archaecyclus Silvestri, 1908, p. 134

Archaecyclus sp.

(Figure 11d)

Test large, convex planispirally coiled, five chambers in the first whorls, later forming an annular

arrangement; the sutures are oblique, the wall calcareous, perforated, having a dark thin layer in middle position. The aperture is interiomarginal in the early stage; after with stolon-like openings at the lateral margins of each chamber (Loeblich and Tappan, 1988).

Occurrence: *Archaecyclus* sp. has been recorded by Jaillard and Arnaud-Vanneau (1993) from Peru.

VSLPP has been only observed in the Llanos del Carmen section.

5. Conclusions

The deposits of the upper part of the El Abra Formation preserved a rich and diverse association mostly composed of larger benthic foraminifera, which are described and illustrated for the studied succession. The species of benthic foraminifera have a significant age-diagnostic value in the El Abra shallow-water deposits, dating the succession studied here as mid-late Cenomanian.

The foraminiferal and algal assemblages are age-equivalent to the Mediterranean associations. Two zones are proposed for the sections from the El Abra Formation: the *Pseudolituonella reicheli* Assemblage Zone and the *Nezzazatinella picardi* Interval Zone.

The *Pseudolituonella reicheli* Assemblage Zone contains a rich and varied benthic foraminiferal association which was reduced to a few foraminifers that survived. The *Nezzazatinella picardi* Interval Zone later also disappeared when the hemipelagic Soyatal deposit took place (*Whiteinella archaeocretacea* Partial Range Zone) due to the large scale flooding and climate perturbations.

The integration of the data provided by the benthic foraminiferal association and the lithology enable a more reliable paleoenvironmental interpretation.

We consider that there was a first episode (mid-late Cenomanian) in the Taninul facies of the El Abra Formation consisting of a warm shallow-water carbonate platform with open circulation and medium-high hydrodynamic energy. The ma

ximum diversity of benthic foraminiferal assemblages coincides with this environment. Later, a decrease of benthic foraminiferal species diversity is recorded, with a few foraminiferal species surviving (*Nezzazatinella picardi*, miliolids, rotalids, and textularids) in association with algae. This change could be related to increasing nutrient availability in mesotrophic conditions.

The drowning event of the platform with a hemipelagic deposit (Soyatal Formation) occurred in the latest Cenomanian. It is marked by the bloom of pithonellids and *r* and *r-k* strategist planktic foraminifera and benthics such as gavellinellids, which are present in a deeper and eutrophic environment.

An environment with restricted circulation from the El Abra facies is distinguished by a shallow-water association of reduced diversity but commonly with numerous individuals of typical miliolid foraminifera. Another intermediate semi-restricted environment with a greater variety of foraminifera is also defined.

The foraminiferal and algae community have a marked Tethysian affinity.

Acknowledgments

This work was supported by DGAPA-PAPIIT IN119208 Project grants. We are greatly indebted to Dr. Rafael Barboza Gudiño (Director of the Geology Institute of the Universidad Autónoma de San Luis Potosí) for providing logistical field assistance. We are very grateful to Drs. Robert W. Scott (Precision Stratigraphy Associates and Tulsa University) and Ioan I. Bucur (Babeş-Bolyai University) for valuable and careful comments and suggestions that much improved the manuscript, and Dr. Esmeralda Caus (Universidad Autònoma de Barcelona) for the observations on the text.

The authors gratefully acknowledge Dr. Francisco Vega Vera (UNAM Mexico) for his precise editorial handling. We thank Joaquín Aparicio for preparing numerous thin sections.
