Study Area: Hanoi, Vietnam

Coordinates: 21°01'42"N 105°51'15"E

Keywords: Pig farming, Omnivorous, Protein requirement.

Policy implications:

Ministries and government agencies would implicate its directions to facilitate export markets for wild pork meat in the northern region of Vietnam, for instance, in Thai Nguyen city, esp. In the context during EVTA to help pork meat export to the European market.

And Huy, D.T.N (2015) also suggest management standards for better management of businesses in various sectors including agriculture.

Abstract

Wild boars are omnivores and sometimes eat indiscriminately; it survives in many different environments, from deserts to mountainous areas. This study used qualitative analysis, synthesis and inductive methods, with statistic data, examined experiences from Asian countries such as Thailand and China and meanings to Vietnam case of feeding wild pigs. Our results identified the amino acid requirement of pigs consists of two components, maintenance needs and production needs. Last but not least, through our analysis, authors suggest Ministries and government agencies consider facilitating export markets for wild pork meat in the northern region of Vietnam, for instance, in Thai Nguyen city. In the context during EVTA to help pork meat export to the European market. With the practical requirements of Vietnam's wild boar farming and natural conditions, the research to determine the reasonable protein level in the diet based on local feed ingredients is an urgent requirement. Solving this urgent scientific problem not only ensures the maintenance of good growth performance for wild boars and hybrids but also has the meaning of saving and taking initiative in food sources in large-scale wild boar and hybrid breeding. In particular, it contributes to preserving and protecting precious pig genetic resources.

Introduction:

Wild boars are often found in large areas, they live in herds, the number can be up to 100 animals mainly of juveniles. Herds of wild boar can travel together on long journeys to new settlements, but do not migrate. Wild boars are more active at night, at dusk and at dawn. When the boar matures, it will leave the herd and live independently (Tisdell, 2013).

Wild boars are omnivores who eat indiscriminately. Daily foods are consist of mushrooms, tubers, rice, rice, fruits, eggs, carrots, vertebrates. wild boar survives in many different environments, from deserts to mountainous areas (Ballari et al., 2014). Animal foods consist of birds, mammals, amphibians, reptiles, carrion, insects, terrestrial arthropods, molluscs. Plant foods are roots, tubers, bark, grass, rice, and fruits. Often consume faeces.

Moreover, When the EU-Vietnam Free Trade Agreement (EVFTA) takes effect, the EU commits to eliminate 85.6% of tariff lines for Vietnamese goods, equivalent to 70.3% of the total export value of Vietnam to EU (source:

www.baodautu.vn, date 24/6/2021).

As per Pligne *et al.*, (2001) Boucane' is a traditional meat product from Reunion that is obtained by salting, drying and hot smoking pork belly. Thanapongtharm (2016) reported that the pig production in Thailand intensified significantly during the last decade, with many economic, epidemiological and environmental implications. As per Thang & Van (2006), there are different types of feeds, different diets, thus the content of nitrogen forms in the intestinal chyme is different. When the boar gets mature (around 50-350 kg) it leaves the herd and lives independently with some domesticated pigs (~ 450 kg). Males are usually larger than females. Wild pigs have 4 pairs of fangs and 6 pairs of breasts (Hang, 2008). It played a central role in the subsistence and culture of China for millennia (Lander *et al.*, 2020).

Our study is to answer the following: What is the appropriate feeding mechanisms of wild pigs, and to know the protein and amino acid requirements? What are food processing and recommendations?

*Corresponding Author: dtanhuy2010@gmail.com

Methodology: A combination of quantitative methods and qualitative methods including synthesis, inductive and explanatory methods.

Results:

Overview on Characteristics of growth and sexual development of wild boars and hybrids: Wild boars grow with the slow trends and reach their maximum size depending on breed, environment and age. The European wild boar is usually much larger in stature than the Asian wild boar. While the Asian wild boar can only be 65-70 cm tall, 120-140 cm long, 70-150 kg in weight, the European wild boar can be up to 90-100 cm tall, 150-160 cm long, and weigh up to 200-350 kg. Males are usually 20-30 kg larger than females (Markina *et al.*, 2004). Newborn pigs are very small, weighing 0.5-0.7 kg, 15-25 cm long. Weaning age 55-60 days; The weight of piglets at weaning is 4-5 kg/head. The age of slaughter can be calculated from 8 to 10 months old; the weight usually ranges from 25-35 kg depending on the needs of the market (Gardner *et al.*, 2013).

Table-1 : Wild pigs growth rate

Monthage	Weight (kg)	Speed of growing (g/days)
0-2	0.5-5	8.33-83.33
2-4	10-12	166.66-200.00
4-6	15-25	250.00-416.66
6-8	25-35	300.00-583.33
8-10	40-50	666.66-833.33

The growth rate (for wild boars that have been raised in Thailand and Vietnam) is slow (average is only about 0.15-0.3 kg/day). The physiological life span of wild boar lasts from 15 to 25 years (Thanapongtharm *et al.*, 2016; Chen *et al.*, 2018).

Food and feeding method:

- Food is full of nutrients, not rancid, mouldy.
- The daily intake of pregnant sows depends on the sow's condition. Skinny sows must increase feed, too fat sows must reduce mixed feed but must increase forage (Geisser & Reyer, 2004).
- In winter, when the temperature in the barn is < 15°C, sows need to eat more (0.2-0.3 kg/day) to compensate for the energy lost due to cold resistance (Knox, 2014).

Basic characteristics of the digestive physiology of pigs: omnivores; the gastric environment contains gastric juice secreted by the gastric glands. The gastric juice has a low pH environment suitable for pepsin activity to break down proteins into albumin, peptone products and a small number of amino acids (Phùng *et al.*, 2004). The pig's small intestine is very long and has many digestive secretions such as pancreatic juice, intestinal juice and bile, in which only pancreatic juice and intestinal juice contain enough enzymes to thoroughly digest nutrients in feed. Therefore, the small intestine is a digestive part full of enzymes that break down nutrients in food into the simplest nutrients, helping the body absorb directly through the intestinal

wall into the bloodstream. Bile juice does not contain digestive enzymes, but it aids in digestive activities, especially fat digestion. The small intestine environment is alkaline and has a special structure, highly adapted to digestion and absorption of food.

Along the intestinal mucosa, there are developed intestinal glands that secrete intestinal secretions in a full-secretory fashion, that is, the glandular cells filled with enzymes fall directly into the intestinal cavity, creating an endogenous nitrogen source up to 30 g/day. This is a feature that affects the accuracy of the digestibility test results in pigs, which cannot be ruled out. In the large intestine of pigs, there is a symbiotic intestinal microflora in the cecum and colon that is capable of breaking down fibres. The large intestine does not secrete enzymes but only continues to break down food by enzymes in the small intestine. This rate of digestion is high or low depending on the retention time in the large intestine (12-16 hours) (Extracted from Phùng *et al.*, 2004). Digestion fibre is 14%, digest protein is 12%, have 9% carbohydrates and 3% lipids of the remaining nutrients digested by the large intestine. The main activity of the large intestine is the fermentation of fibre due to the action of the microflora in the cecum and colon and the decomposition of excess protein in food by rotten bacteria to form Crezon toxins. Fenol, Idol, Scatol. These toxins are absorbed into the bloodstream and detoxified in the liver. If these substances are too much, they will poison the liver and be excreted through faeces, causing unpleasant rotten odours, polluting the environment, and also cause diarrhoea in pigs (Thang *et al.*, 2006).

Thus, in all cases, fermentation by microorganisms in the caecum and colon of pigs produces microbial biomass that is excreted in the faeces, and this nitrogen source, together with excess nitrogen in the feed, causes significant errors. Important in determining the net digestibility of nitrogen in feed. This compels nutritionists to study exclusions in experimental methods to test digestibility. The digestive activity of pigs during the day is usually greater than at night, and the time the feed stays in the gastrointestinal tract in pigs is about 24 hours. However, there is a small portion of food that will be discarded in about 4-5 days (Phùng *et al.*, 2004).

Protein and amino acid requirements of pigs: these in pigs consists of two components, maintenance needs and production needs. Recognize that maintenance is not a physiological reality but a conceptual fit (Fuller, 1989).

In mature individuals this also means constant body mass, however, in immature animals the mass is kept constant by keeping nutrition, promoting growth and continuing to increase body protein, while body fat loss (Fuller *et al.*, 1979).

To maintain nitrogen balance it is necessary to supply amino acids at a rate equal to the rate at which they are lost

through metabolism, secretion or excretion from the body. Mandatory loss processes arise through them, the following processes being the most important and quantitative in nature.

Synthesis of non-protein substances: some of the essential amino acids cannot be used in the synthesis of physiologically important substances such as Hormones, neurotransmitters and important products of biological transformation side. essential complementary amino acids are lysine, methionine (and cysteine), phenylalanine (primarily through tyrosine), histidine, and tryptophan (Murphy & Percy, 1993).

Amino acids lost from epidermal cells: Loss of amino acids from epithelial cells occurs free amino acids and proteins. Since pigs are non-per spirants, loss through perspiration is expected to be minimal. In particular, skin and hair shed and are replaced continuously, estimated skin and hair nitrogen loss in pigs averaged 55 kg for a range of 0.25 - 0.50 g/d, depending on feeding. and ambient temperature. By extrapolation (Fuller, 1991) it is estimated that if the feed were restricted to such a degree to stop growth, these losses would be reduced to approximately 1 g N/d or 5 mg/d. This is only about 2% of the total N that needs to maintain. However, this estimate, which includes extensive extrapolation, is unlikely to be a direct estimate.

In contrast, much of this is dependent on proteolysis and a large proportion of amino acids are reabsorbed, estimates of minimal loss from the gastrointestinal tract have been carried out by determining amino acids. enter the large intestine when animals are fed a protein-free diet. In a nutshell, the maintenance requirement is the amount of protein that replaces the proteins that are required to be lost from the body consisting mainly of skin proteins and various nitrogen metabolism end products in the urine. Forced losses are generally assessed by determining nitrogen excretion when fed a protein-free diet and have a normal relationship to body mass. Whether or not this estimate is applicable, to animals fed diets with normal levels of protein in the feed (Thang *et al.*, 2006).

Interaction relationship between protein and metabolic energy: studies suggested that the protein accumulation rate of pigs can be inhibited because the feeding process does not provide enough energy and protein. The rate of protein accumulation can be influenced relatively independently of the energy or protein the animal receives daily through food. When formulating diets for pigs, one must establish a balance between protein and energy in order to maximize protein accumulation and significantly reduce fat accumulation.

Changes in the content of some amino acids in the internal organs can be attributed to the energy and protein intake that affect blood and organ mass (Bikker *et al.*, 1994), and related fractions increased with increasing energy intake. The mass of blood, kidney, pancreas and

spleen also increased with increased protein intake (Excerpt from Giang, 1999), protein content in blood, digestive system and liver account for 5, 4 and 3% respectively compared with whole-body protein. Different levels of energy intake would greatly affect the content and composition of acids. The content of lysine, threonine, histidine, tyrosine, aspartic acid and serine in the internal organs are reported as 10 - 30% higher, while cysteine, leucine, phenylalanine valine was 40 - 50% higher than that in the carcass and the organs. The content of methionine, arginine, isoleucine, glutamic acid and glycine in the carcass was 10 - 30% lower than that of the organ.

Discussion:

All living, developing and reproductive activities of pigs are associated with the process of using and exchanging energy. Energy in food is stored in the physical forms of food such as fat, sugar, protein, and carbohydrates. Pigs receive food energy from the outside, through digestion, absorption in the digestive tract into the body and synthesis into fat, glucose, and pure protein of the pig's body.

The pig's body wants to function like walking, breathing, circulating, digesting, excreting etc. Heat energy turns into function and acts on the body's organs to function in a rhythmic manner, through the control of nerves, hormones, and enzymes. Energy participates in the construction of nerve cells, nerve sheaths, forming important compounds such as lipoproteins, glycoprotein found in nerve cell membrane tissue, in exocrine glands. Fat both stores energy and acts as a cushion under the skin, surrounding the digestive tract, circulation, and respiration to resist mechanical impact, heat and cold for the body. Pigs need more energy than other cattle because the genetic makeup of pigs accumulates fat about 45-50% (Thom *et al.*, 2021).

The Results of evaluating the quality of experimental pork. In addition, the experiment also assessed meat quality through a number of criteria presented in Table-2.

Table-2: Results of evaluation of experimental pork quality

#	Content	Lot TN1 $\bar{X} \pm m_x$	Lot TN2 $\bar{X} \pm m_x$	Lot TN3 $\bar{X} \pm m_x$
1.	Meat color after surgery (Minolta L*) (brightness)	48.02±1.11	47.95±1.54	47.83±1.36
2.	Meat toughness (kg/cm ²)	4.85±1.23	4.89±1.56	4.95±1.25
3.	pH of tenderloin right after surgery	6.8±0.32	7.0±0.12	7.1±0.15
4.	Tenderloin pH after 45 min.	5.5±0.21	5.3±0.24	5.2±0.26
5.	Cholesterol (mmol/L) blood	1.65±1.23	2.15±0.91	3.11±1.89
6.	Triglycerid (mmol/L) blood	2.3±1.34	2.8±0.98	2.6±1.12

A lot of research in this field determining the protein and energy needs of pigs to promote growth, complete development, reduce costs and increase livestock

efficiency have been carried out. The balance between protein/ME in pigs is an important requirement for growth, meat quality, and lean percentage at the growing stage of pigs.

Survey results on 77 wild boar breeding facilities across the country by the National Institute of Livestock Production showed that 61.1% of establishments raised pure Thai wild boar, 38.9% of establishments raised many types, including wild boar. Thailand, Vietnam, native pigs and hybrids. There are 6 establishments that also raise pure Vietnamese wild boar. The Thai wild boar is imported from Thailand. However, in the South, there are also Malaysian wild boars.

The balance of protein in the diet is a measure to supplement protein feed for wild boars, which is a measure to increase the efficiency of industrial-oriented hybrid wild boar farming to meet market demand. The research by Van de Ligt *et al.* (2002), Thong & Liebert (2004) on the balance of amino acids and proteins in foreign crossbred pigs have been done. Meat farming has given good results. Thus, the balance of protein and energy levels for hybrid wild boar to assess the growth ability through the stages, both to exploit the growth ability of high-quality wild boar and to ensure naturalness. Their wildness is suitable for the northern climate conditions of Vietnam.

Kvisna *et al.* (2005) studied the process of raising wild boar in Thailand got good results. Besides, Litten *et al.* (2004); Kuhn *et al.* (2004) also studied that the addition of cassava flour to the wild boar's diet was effective but increased the percentage of fat higher than the addition to the corn-only diet.

Conclusively, the practical requirements of Vietnam's wild boar farming and natural conditions, the research to determine the reasonable protein level in the diet based on local feed ingredients is an urgent requirement. Solving this urgent scientific problem not only ensures the maintenance of good growth performance for wild boars and hybrids but also has the meaning of saving and taking initiative in food sources in large-scale wild boar and hybrid breeding. big is easy. In particular, it contributes to preserving and protecting precious pig genetic resources.
