Abstract: This project discusses about splitting and defecation at public places or in open environment that impact environmental or the health. So to avoid this case study is to be made by Examining the existing literature, legislation, case law, and other sources of information practise, as well as analysing and proposing remedies is a far more prevalent practise than is often acknowledged. The most important attempts have been concentrated on preventing these as a tool to evade the environmental impact assessment EIA, but it is a much more complex subject, with many ways of dividing or defecating as well as reasons for doing so. Increasing the effectiveness of strategic environmental assessments For example, a higher engagement of the approving authority, precise laws, case-by-case investigations rather than thresholds, required scoping, and the avoidance of project components being excluded during the EIA are all actions that should be taken to avoid this practise. Defecation and open splits can pollute the environment and cause health issues. So the project is designed using moisture sensors that are place at a location along with ESP 32 WiFi module with camera to send picture images of the person doing so of either splitting or defecation. The system immediately takes the picture image of the person doing so and sends it to the concern authorities through IOT to the BLYNK app of the mobile. The Internet of Things (IoT) is a network of physical items that employs sensors, electronics, software, and connections to share data. There is no need for humans to interface with these systems. The way real-world systems are interconnected through the internet has been transformed by Internet of Things (IoT)-based solutions. At this time, the use of IoT-based systems has expanded to include real-time detection and warning systems. Cost, on the other hand, has been a major consideration in the development and deployment of IoT systems.

I. INTRODUCTION

The Internet of Things (IoT) is a network of physical objects (or "things") that are embedded with sensors, software, and other technologies in order to communicate with other devices and systems over the internet. The sophistication of these devices ranges from simple domestic items to sophisticated industrial instruments. There are currently over 7 billion connected IoT devices.

In recent years, the Internet of Things has emerged as one of the most important technologies of the twenty-first century. It is now possible to connect common objects to the internet via embedded devices, such as kitchen appliances, autos, thermostats, and baby monitors, allowing for seamless communication between people, processes, and things.

Thanks to low-cost computers, the cloud, big data, analytics, and mobile technologies, physical items can communicate and collect data with minimal human contact. In today's hyperconnected world, digital systems can record, monitor, and change every interaction between connected devices. Although the physical and digital worlds clash, they complement one other.

What Innovations Have Changed the World? Internet of Things Possible?

While the concept of the Internet of Things has been around for a long time, but current technological advancements have made it a reality. Low-cost, Sensor technology with reduced power consumption is offered. Thanks to the availability of low-cost, high-reliability sensors, IoT technology is becoming more accessible to more manufacturers.

Connectivity. Sensors may now be easily connected to the cloud and other "things" for efficient data transfer thanks to a range of internet network protocols.

Platforms for cloud computing Cloud platforms are becoming more widely available, allowing organisations and consumers to have access to the infrastructure they need to grow up without having to handle it all themselves.

Machine learning and analytics. Thanks to advancements in machine learning and analytics, as well as access to diverse and vast volumes of data stored in the cloud, businesses can gain insights faster and more easily. IoT data feeds these technologies, and the development of these linked technologies continues to push the boundaries of IoT.

II. LITERATURE SURVEY

If there is something that people get to hear very often when airborne diseases pose a threat, it is the advice on coughing/sneezing hygiene and frequent handwashing. Another topic that receives little or no attention is avoiding spitting in public.. Like cough, spitting too, according to doctors and public health officials, can lead to spread of infections.

In a city like Chennai, people spitting on roads continues to be a common sight. Doctors and public health officials say that many spit on the road while travelling by two-wheelers, cars or buses, with no second thought about others on the road.

When respiratory infectious diseases such as H1N1 influenza peaks in the State, and now, with the outbreak of the coronavirus disease in China, the emphasis is largely on cough etiquette and hand hygiene. Spitting is most often the last thing to be emphasised. This, despite Tamil Nadu having a legislation that prohibits spitting —..

With the enforcement of the Cigarettes and Other Tobacco Products Act, this Act took the back seat, and along with it went the prohibition on spitting, a public health official said.

Spitting in a public area demonstrates a lack of civic sensibility as well as a lack of sanitary awareness. “Of course, a lot has changed in the last 10-20 years, but people continue to spit in public. People should be made to believe that spitting isn't a positive thing. Spitting can spread infectious organisms to others, which is bad for your health.,” a senior doctor of the Rajiv Gandhi Government General Hospital said.

Like cough and sneeze, droplets from the spit of an infected person can transmit infections to others, especially under favourable conditions, doctors said.

Leading by example

There are instances where places have been declared spit-free., who was instrumental in making the college and the hospital campuses spit-free zones, said, “It has been taught in various classes that Singapore and the U.K. banned spitting because of the high prevalence of tuberculosis. If everybody stops spitting, it will influence or force a person with TB to stop spitting. Spit-free is not about aesthetic cleanliness but also about public health,” he said.

“Covering the mouth while coughing, covering the nose while sneezing and not spitting are three important hygiene practices. It is necessary to control the spread of respiratory-transmitted infections such as TB, influenza, common cold, pneumonia-causing viruses such as SARS and also the present coronavirus,” he added.

III. METHODOLOGY

IV. IMPLEMENTATION

A. Hardware

- 1) ESP32 camera
- 2) FTDI CHIP
- 3) POWER SUPPLY
- 4) RAIN SENSOR
- 5) NPN TRANSISTOR
- 6) 1K AND 10K RESISTORS
- 7) BLYNK APP

We observe that once some person spits or defeacates at public places where we have placed this setup the automatically the rain sensor detects it and a message is sent to the officials through the blynk app also through a mail

The officials will then check with their database and send the person the fine that has to be paid or the concerned action they want to take

V. RESULTS

VI. CONCLUSION

The project "IOT BASED SYSTEM TO AVOID SPITTING AND DEFEACTION" has been created and tried successfully. It was created by incorporating functionality from all of the hardware that was utilised . Every module has been carefully considered and arranged, resulting in the best possible operation of the unit. Second, the idea was effectively implemented employing very advanced integrated circuits and growing technologies.
