## ABSTRACT

The Mg/Li ratio is an important factor in the extraction of Li<sup>+</sup> from salt lake brine. Since Mg<sup>2+</sup> can exist by competing with Li<sup>+</sup> in the carbonate phase, the cost and energy consumption of Li extraction from salt lakes, is directly affected by the ratio. This article considers the influence of different content of Mg<sup>2+</sup> on Li<sub>2</sub>CO<sub>3</sub> crystal in Na<sup>+</sup>, Li<sup>+</sup>, CO<sub>3</sub><sup>2-</sup>//H<sub>2</sub>O crystallisation system. In the experiment and calculation simulations, the morphology, particle size and purity of Li<sub>2</sub>CO<sub>3</sub> crystals under various Mg/Li ratios were studied. We analysed the mechanism of Mg<sup>2+</sup> in the Li<sub>2</sub>CO<sub>3</sub> crystallisation system, and established the governing equation in relation to the Mg<sup>2+</sup> content and specific surface area. This research provides theoretical guidance for improving the utilisation rate of Li resources and strengthening the Li<sub>2</sub>CO<sub>3</sub> crystallisation process in salt lakes.

*Keywords:* Salt lake; Li<sub>2</sub>CO<sub>3</sub>; Mg<sup>2+</sup>; Specific surface area; Adsorption and doping; Density functional theory
