Model	Description
WRF	Three nested domains covering the inland China with grid resolutions of 36 km × 36 km, 12 km × 12 km and 4 km × 4 km were set for the simulation domains. The initial and boundary conditions for WRF were based on the North American Regional Reanalysis data archived at National Center for Atmospheric Research (NCAR, https://rda.ucar.edu/datasets/ds083.2/index.html#!cgi-bin/datasets/getWebList?dsnum=083.2&gindex=2). In addition, surface (https://rda.ucar.edu/datasets/ds461.0/index.html#!cgi-bin/datasets/getWebList?dsnum=461.0&gindex=7) and upper (https://rda.ucar.edu/datasets/ds351.0/index.html#!access) air observations obtained from NCAR were used to further refine the analysis data through data assimilation.
CMAQ	The CMAQ model version 5.0.2 was used to simulate air quality over the modeling period. The modeling was conducted from Oct. 1 to Oct.30 in 2018. Gas phase chemistry was based on CB05 (Carbon Bond 05) mechanism, the aerosol dynamics/chemistry was based on aero6 (Sixth-generation modal CMAQ aerosol model) module (cb05tucl_ae6_aq) (Yarwood et al., 2005; Whitten et al., 2010), ISORROPIA II inorganic chemical mechanism (Fountoukis and Nenes, 2007) was adopted. The CMAQ were two nested modeling domains which took Dom2 and Dom3 from WRF, but both indented 6 grids each side to reduce the impact of the boundary effect, and we excluded the first 7 days CMAQ simulation results to minimize the impact of initial conditions. PM size representation was based on three log-normal modes (nuclei, accumulation, coarse) (Chapel Hill, 2012).
MEIC	The Multi-resolution Emission Inventory for China (MEIC) model has been developed and maintained by Tsinghua University since 2010, aiming to build a high-resolution Inventory of anthropogenic air pollutants and carbon dioxide emissions in China. Anthropogenic emission data from the monthly MEIC which include five types of emission categories (power plant, industry, residential, vehicle and agriculture) at the year 2017 were used. The inventory contains the emissions of ten major species (including sulfur dioxide (SO ₂), nitrogen oxides (NO _x), carbon monoxide (CO), non-methane volatile organic compounds, ammonia (NH ₃), fine particulate matter (PM _{2.5}), coarse particulate matter (PM ₁₀), black carbon (BC), organic carbon (OC) and carbon dioxide (CO ₂) (http://meicmodel.org/) (Liu et al., 2017a; Zheng et al., 2018). In addition, the Inventory Spatial Allocate Tool (ISAT) was used in this work (Wang et al., 2019).

Equation	$\delta_{i} = \frac{\frac{C_{i_case} - C_{i_base}}{C_{i_base}} \times 100\%}{P_{j_case} - P_{j_base}}$
Description	C_{i_case} is the simulation result of gas pollutant i in different sensitivity experiment cases, $\mu g/m^3$; C_{i_base} is the simulation result of gas pollutant <i>i</i> in base case, $\mu g/m^3$; P_{case} is the sum of the percentage of perturbed components which cause the variation of gas pollutant in sensitivity experiment cases, %; P_{base} is the percentage of P_{case} in base case, %.

1DBL represent the simulation results of case DBL in site 1 (which is listed in Table S25 'cases and sites' column), and the others named by the same rule.

Fig. S1 The selected speciation profile of $PM_{2.5}$ from different database In SPE, the selected source profiles were average profile developed from original profiles of the source category group in SPECIATE database, the power plant (PP) source profile code was 91041, industrial process (IN) was 900162.5, Residential coal combustion (RE) was 91155, Transportation sector (TR) was 91022 and 91162. In LOC, the selected source profiles were from SPAPPC database which were measured from local emission sources.
