Heat of Formation

Messierle and Kraus (1) have reported the dissociation energy as 49300 ± 300 cm⁻¹ from the variation of the rotational structure cut-off with vibrational level in the c¹Π_g state. This state dissociates into C³P + C³P, due to an avoided crossing (2), these dissociation products are those of the ground state. The uncertainty in the determination is generous and thus we adopt D₀ = 140.95 ± 0.9 kcal/mol, using ΔHf₀(C, g) = 169.576 kcal/mol (3).

Brewer et al. (4) have reviewed several other earlier determinations which confirm ΔHf₀ = 185 ± 5 kcal/mol. The extensive mass spectrometric data of Drowart et al. (5) yield a 3rd law ΔHf₀ = 199.2 ± 1.4 kcal/mol in excellent agreement with the adopted value.

Heat Capacity and Entropy

The observed molecular constants and electronic levels were taken from Ballik and Ramsay (2). The estimated parameters are from the correlation calculations of Fougere and Nesbet (6) and Clementi (7), the electronic levels are T₀ values. Not all predicted states were included since the contribution of levels above 40000 cm⁻¹ is negligible. The functions were calculated from the partition function $Q = Q_e \sum_i g_i \exp(-C_2 \epsilon_i / T)$, the values for Q_e and Q_v were calculated with first order anharmonic corrections. The functions are similar to those reported by Altman (8) and Clementi (7) but include several additional states.

Heat of Formation

The electron affinity of C₂ has been obtained by Honig (1) as 4 ± 0.8 eV from the difference in heats of sublimation of neutral C₂ and C₂⁻ and the work function of graphite. Thus, we have the reaction

$$C_2(g) + e^- \rightarrow C_2^-(g) \quad \Delta H_0 = -92.2 \pm 20 \text{ kcal.}$$

Using $\Delta H_f^0(C_2, g) = 198.2 \text{ kcal/mol}$ (2), we obtain $\Delta H_f^0(C_2^-, g) = 106 \pm 20 \text{ kcal/mol}$, which is adopted.

A value for the heat of formation may be obtained from a linear Birge-Sponer extrapolation of the ground state vibrational levels, which gives 195.8 kcal for the reaction

$$C_2^-(g) \rightarrow C(g) + C^-(g).$$

With auxiliary data (2) this yields $\Delta H_f^0(C_2^-, g) = 114.5 \text{ kcal/mol}$, in good agreement with the adopted value.

Heat Capacity and Entropy

The molecular constants and electronic levels are from Herzberg and Lagerqvist (3). The values are not definitely ascribed to C₂⁻ by Herzberg and Lagerqvist, but there is a good deal of evidence to support this assignment. Recently Milligan and Jacox (4) have shown that matrix isolated bands previously attributed to C₂(g) are enhanced in the presence of a photoelectron source. The matrix spectra correspond to the gas system reported by Herzberg and Lagerqvist (3) and leave little doubt that the species is C₂⁻.

The estimated electronic level is assumed to be a ²Π state and is obtained from the isoelectronic CN(g) (2).

 Rotational Constant: B₀ = [0.4809] cm.⁻¹

Heat of Formation

ΔH_f^0 298.15 was estimated as a lower positive limit by National Bureau of Standards Report No. 6645, "Preliminary Report on the Thermodynamic Properties of Light-Element Compounds," January, 1960.

Heat Capacity and Entropy

The vibrational frequencies, bond angle, configuration and moment of inertia, 5.82×10^{-39} g. cm.², were estimated by Chupka, Berkowitz, Gleason, and Inghram, J. Phys. Chem. 62, 611 (1958). Bond distances were calculated assuming the C-C bond distance was the same as in acetylene.

$\Delta H_f^\circ = [49.3 \pm 10] \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = [50.1 \pm 10] \text{ kcal/mol}$

Heat of Formation

The heat of combustion (ΔE₂₉₈^o) of C₂Cl₄(g) has been determined by the "Quartz Wool" method by L. Smith, L. Bjellerup, S. Krook and H. Westermarck, Acta Chem. Scand. Z, 65 (1953). The free chlorine produced from combustion was reduced to hydrogen chloride by a quartz spiral moistened with a solution of arsenious acid in the combustion bomb. Based on the reported results, the enthalpy change at 298°K for the reaction C₂Cl₄(g) + 2H₂O(l) = 2CO₂(g) + 4HCl(600H₂O) is evaluated as -198.40 kcal/mol, using recent auxiliary data from U. S. Natl. Bur. Std. Tech. Note 270-1, 1965 and V. B. Parker, U. S. Natl. Bur. Std. NBS-RS-2, 1965, and Cp for C₂Cl₄(l) from V. Y. Kurbatov, J. Gen. Chem. USSR(Eng. Transl.) 16, 372 (1948). Employing ΔH_f^o = -94.054, -39.823 and -68.315 kcal/mol for CO₂(g), HCl(600H₂O) and H₂O(l), respectively, we calculate the heat of formation for C₂Cl₄(g) as -12.367 kcal/mol. Incorporating this value with the value ΔH_f^o = 9.4 kcal/mol obtained from E. Efring, Ph.D. Thesis, University of Lund, 1938, we derive ΔH_f^o = -2.97 ± 0.7 kcal/mol for C₂Cl₄(g).

Heat Capacity and Entropy

The molecular structure of C₂Cl₄(g) was investigated by the sector-visual method of electron diffraction by C. H. Ramachandra and R. L. Livingston, Current Sci. 27, 330 (1958). The reported bond distances and angle are in agreement with those measured by I. L. Karle and J. Karle, J. Chem. Phys. 20, 63 (1952), using the sector-microphotometer method, and W. N. Lipscomb, Ph.D. Thesis, California Institute of Technology, 1946. The molecular structure has also been determined by L. O. Brockway, J. Y. Beach and L. Pauling, J. Am. Chem. Soc. 57, 2693 (1935), H. de Laszlo, Nature 135, 474 (1935), and R. W. Dornte, J. Chem. Phys. 1, 566 (1933), by use of electron diffraction. The values reported by Ramachandra and Livingston, loc. cit., are adopted.

The vibrational spectra of tetrachloroethylene have been studied by numerous investigators. The vibrational frequencies assigned by D. E. Mann, N. Acquista and E. K. Plyler, J. Res. Natl. Bur. Std. 52, 67 (1954), are adopted here. These authors also reviewed the results of earlier investigations in detail.

The electronic levels and quantum weights are obtained from G. Herzberg, "Electronic Spectra of Polyatomic Molecules," D. Van Nostrand Co., Inc., New York, 1966.

The three principal moments of inertia are: I_A = 4.88344 × 10⁻³⁶, I_B = 6.28884 × 10⁻³⁶ and I_C = 1.11723 × 10⁻³⁷ g cm².

C-C = 1.55 Å
Cl-C-C = 109°
σ = 6

Vibrational Frequencies and Degeneracies

Smith et al. (1) determined the heat of combustion of C₂Cl₆(g) to be ΔH₂₉₃^o = -718.7 ± 2 cal/g (uncorrected) by use of the "Quartz Wool" method. The free chlorine produced was reduced to HCl by employing the quartz spiral moistened with a solution of arsenious acid in the combustion bomb. Adopting the reported results and recent auxiliary data (2, 3, 4), we evaluate the values ΔH₂₉₈^o = -717.525 and ΔH₂₉₈^o = -48.58 kcal/mol for C₂Cl₆(g). Kirkbride (5) measured the enthalpy changes as -32.0 and 4.7 kcal/mol for the following two reactions by solution calorimetry: C₂Cl₆(l) + Cl₂(g) = C₂Cl₄(aq) and C₂Cl₆(g) = C₂Cl₄(aq). Hence we obtain ΔH₂₉₈^o = -49.07 kcal/mol for C₂Cl₆(g), using ΔH₂₉₈^o (C₂Cl₄, l) = -12.37 kcal/mol. This value is in reasonable agreement with the adopted value -48.58 kcal/mol.

Hexachloroethane (c) has three modifications, namely triclinic, monoclinic and cubic, with transition temperatures of 318 and 345°K (4). The sublimation pressures over the different phases have been measured by Ivin (8), Lee (2), and Nitta (29). Based on these data, values for ΔH₂₉₈^o (triclinic) are derived by a modified second law method to be 16.5, 17.1 and 14.8 kcal/mol, respectively. The analysis depends on the Cp and ΔH^o data determined by (4). The order of chemical Company, Midland, Michigan. Pressures reported by Nelson (6) are systematically lower than the above data by about 10 per cent; therefore, his data are not used. Third law analysis is not applicable to the pressure data due to lack of S₂₉₈^o (triclinic). Adopting ΔH₂₉₈^o = 16.5 and ΔH₂₉₈^o = -48.58 kcal/mol for C₂Cl₆ (triclinic), we obtain ΔH₂₉₈^o = -32.08 kcal/mol for C₂Cl₆(g).

The equilibrium constant at 776°K for the reaction C₂Cl₆(g) = C₂Cl₄(g) + Cl₂(g) was reported as 0.8 ± 0.1 (atm) by Puyo et al. (3). The corresponding enthalpy change at 298°K is evaluated to be 30.8 kcal/mol by the third law method, yielding ΔH₂₉₈^o(C₂Cl₆, g) = -33.77 kcal/mol which is in fair agreement with the adopted one.

Heat Capacity and Entropy

The molecular structure of C₂Cl₆ has been studied previously by means of infrared and Raman spectroscopy (10), X-ray (11), and electron diffraction (12-18). The molecule was found to be in the staggered position in the vapor and solid states. The bond distances and angles adopted here are those reported by Swick et al. (16).

Incomplete assignments of vibrational frequencies for C₂Cl₆(g) were reported by many investigators (21-24). The adopted frequencies, except the torsional mode ν₁, are obtained from Carney et al. (19). The torsional mode ν₁ is treated as a hindered internal rotation, and thermodynamic properties are calculated (25) from the barrier height of V₀ = 12.6 kcal/mol which was evaluated by Karle (20) from electron diffraction data. The value of S₂₉₈^o is calculated based on S₂₉₈^o = 105.355 eu which is derived from the free rotor value S₂₉₈^o = 108.121 eu by subtraction of the entropy difference between a free rotor and hindered rotor at 400°K. Internal rotation contributions to Cp at temperatures below 350°K could not be calculated since they are beyond the range of the values tabulated by Pitzer (25). These Cp contributions are estimated by graphical interpolation between internal rotation values above 350°K and the corresponding harmonic oscillator values (ν₁ = 67 cm⁻¹, below 150°K. This calculation presumes that the internal rotation approaches harmonic oscillation as V/RT > 1.

The three principal moments of inertia are: I_A = I_C = 1.1367 × 10⁻³⁷ and I_B = 9.564 × 10⁻³⁶ g cm².

Heat of Formation

M. Farber, M. A. Greenbaum, M. A. Frisch, H. C. Ko, G. Grenier and E. Graper, Rocket Power Inc., 3rd Quarterly Report, AFPL-TR-67-147, Contract F04611-67-C-0010, May 1967, have obtained equilibrium-weight-change data over the C-CF₄ system. Our reanalysis of these data assumes that the equilibrium constants for CF₄, CF₃ and CF₂ are those in the JANAF Tables, and that C₂F₂ was the only other C-F species present at equilibrium. This gives maximum possible concentrations of C₂F₂ and places a lower limit on the heat of formation. The ΔH_f⁰(C₂F₂, g) values so obtained range from +10 kcal/mol from data at 2200°K to -10 kcal/mol from data at 2373°K; we adopt a weighted mean of +5.5 kcal/mol. This value still predicts complete dimerization of CF at 1 atmosphere pressure below about 2200°K, but only CF would exist under experimental conditions such as the study by Farber.

Farber et al. also investigated the mass spectrum of the vapor over the C-CF₄ system and did not detect any ion ascribable to C₂F₂. This is additional support for the value adopted.

The C-C bond dissociation energy in C₂F₂ is 113 kcal/mol, using the JANAF CF(g) table (Dec. 31st, 1967). This value is 115 kcal weaker than the bond dissociation energy of acetylene. In order to explain such a large decrease, a crossing of the repulsive approach of two ²H CF molecules with an attractive approach of two ¹F CF molecules may be postulated. This follows the reasoning used by J. P. Simons, Nature 203, 1308 (1965), to explain the bond dissociation energy of C₂F₄.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that for C₂H₂(g). The C-F and C-C bond distances are estimated from those in HC = CF reported by J. K. Tyler and J. Sheridan, Trans. Faraday Soc. 59, 2661, 1956. The asymmetric stretching frequency, ν₃ = 1149 cm⁻¹, was observed by J. Heicklen and V. Knight, J. Phys. Chem. 69, 2484 (1965). The other vibrational frequencies were estimated by comparison with those for C₂H₂(g) and C₂H₂F₂(g) reported by G. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand Company, Inc., New York, 1945, G. R. Hunt and M. K. Wilson, J. Chem. Phys. 34, 1301 (1961), and J. K. Brown and J. K. Tyler, Proc. Chem. Soc. 1961, 13 (1961). The moment of inertia is 2.3735 x 10⁻³⁸ g cm².

2271 (1)	1215 (2)
1228 (1)	625 (2)
801 (1)	464 (2)
521 (1)	192 (2)

Bond Distances: C-F = 1.335 Å C-C = 1.461 Å CN = 1.153 Å

Bond Angle: F-C-F = 107.5° F-C-C = 111.38°

Product of the Moments of Inertia: $I_A I_B I_C = 1.18645 \times 10^{-113} \text{ g}^3 \text{ cm}^6$

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF₃, C₂F₄, and CF₃X (X = H, Cl, Br, I, CN). Details of the input data and adjustment are given in (1). Input included a calorimetric link to NF₃(g) and CF₄(g) plus an equilibrium link to C₂F₆(g) and C₂N₂(g). The calorimetric study (2) gave $\Delta H_f^\circ = -824.4 \pm 0.6$ kcal/mol at 298.15 K for the reaction $3\text{CF}_3\text{CN(g)} + 5\text{HF}_3\text{(g)} + 6\text{CF}_4\text{(g)} + 4\text{H}_2\text{(g)}$. Equilibrium data (3) in the range 865-925 K give ΔH_f° (3rd law) = 10.59 and ΔH_f° (2nd law) = 10.59 $\pm$ 0.20 kcal/mol at 298.15 K for the reaction $\text{C}_2\text{F}_6\text{(g)} + \text{C}_2\text{N}_2\text{(g)} + 2\text{CF}_3\text{CN(g)}$. The entropy difference, ΔS_f° (2nd law) = ΔS_f° (3rd law), is 0.0 $\pm$ 1.5 gibbs/mol. Deviations between the selected ΔH_f° and the two observations are 1.37 and 0.15 kcal/mol, respectively, both considerably less than the overall uncertainties including those in auxiliary values of ΔH_f° . Subsequent to the adjustment, Curtutt and Sinke (4) reported $\Delta H_f^\circ = -197.6 \pm 0.9$ kcal/mol from a calorimetric study of CF₃CN(g) + 1.25 O₂(g) + 1.5 H₂O(l) + 2 CO₂(g) + 0.5 N₂(g) + 3 HF(120 H₂O). Their result of $\Delta H_f^\circ = -118.4 \pm 1.2$ kcal/mol is confirmation of the selected value.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction data by Danford and Livingston (5) and from microwave data by Sheridan and Gordy (6) and Thomas et al. (7). These studies are in substantial agreement except for a difference of about 0.04 Å in the C-C bond distance. We adopt the results of Thomas et al. (7) since they are based on data for several isotopic species. Principal moments of inertia are $I_A = 14.676 \times 10^{-39}$ and $I_B = I_C = 28.482 \times 10^{-39} \text{ g cm}^2$. Vibrational frequencies are taken from the assignments of Edgell and Potter (8). All values except ν_9 are from infrared spectra of the vapor phase. Raman spectra of the liquid provide ν_9 and confirm the infrared data. Similar assignments have been given by Janz and Wait (9) based on spectra of Wait and Jenz (10).

Face and Bobka (11) used low temperature calorimetric data to derive the entropy of the ideal gas at the normal boiling point of 205.47 K. The experimental value of 65.01 $\pm$ 0.2 gibbs/mol is in good agreement with 65.03 gibbs/mol obtained from this table. The largest uncertainty in Cp° and S° probably arises from neglect of anharmonicity and rotational distortion. Uncertainty in the entropy is estimated to vary from 0.1 to 0.5 gibbs/mol over the range 300 to 1000°K. Discussions of the neglect of anharmonicity are given on the tables for CClF₃(g) and CF₄(g).

TETRAFLUOROETHYLENE (C₂F₄)

(IDEAL GAS)

GFW = 100.0159

Point Group D_{2h}ΔH_f⁰ = -156.6 ± 0.7 kcal/molS⁰_{298.15} = 71.678 ± 0.1 gibbs/molΔH_f⁰_{298.15} = -157.4 ± 0.7 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω ₁ , cm ⁻¹	ω ₂ , cm ⁻¹	ω ₃ , cm ⁻¹	ω ₄ , cm ⁻¹
1872 (1)	1340 (1)	1337 (1)	
778 (1)	551 (1)	218 (1)	
394 (1)	406 (1)	1186 (1)	
190 (1)	508 (1)	558 (1)	

Bond Distance: C-F = 1.313 Å C-C = 1.313 Å

Bond Angle: F-C-F = 114°

Product of the Moments of Inertia: I_AI_BI_C = 1.5877 × 10⁻¹¹³ g³ cm⁶

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF₃, CF₃X (X = H, Cl, Br, I, CF₃) and C₂F₄. Details of the input data and the adjustment are given in (1). In this case, the selected ΔH_f⁰ corresponds to the weighted average of three calorimetric studies (2, 3) which may be reduced to the following:

Reference	Reaction	ΔH _f ⁰ _{298.15} kcal/mol	ΔH _f ⁰ kcal/mol
(2)	C ₂ F ₄ (g) + CF ₄ (g) + C(graphite)	-65.4 ± 0.5	-157.6 ± 0.6
(2)	C ₂ F ₄ (g) + 2H ₂ (g) + 4HF(50 H ₂ O) + 2C(graphite)	-150.9 ± 1.2	-156.2 ± 1.3
(3)	C ₂ F ₄ (g) + 4Na(c) + 4NaF(c) + 2C(graphite)	-392.9 ± 1.3	-157.2 ± 1.4

Amorphous carbon was formed in all three calorimetric reactions and separate combustions were made to refer the observed product to the standard state of graphite. Other calorimetric studies (4, 5, 6) are omitted because of apparent uncertainties in the reductions to the standard-state reactions.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction data by Karle (7), Broun (8) and Young (9). The resulting structures differ in minor respects, particularly in the exact location of the two carbons. Values from Karle (7) are adopted since they are intermediate between the others. Values from Young (9) and Broun (8) correspond to changes of ± 2.4% in the product of the moments of inertia. Principal moments of inertia for the adopted structure are I_A = 15.30 × 10⁻³⁹, I_B = 25.46 × 10⁻³⁹ and I_C = 40.76 × 10⁻³⁹ g cm². Vibrational fundamentals are those selected by Shimanouchi (10) from the data of Mann (11), Nonfils (12) and Nielsen (13).

Furukawa (14) reported low-temperature calorimetric data from which the ideal gas entropy may be derived as 64.54 ± 0.09 gibbs/mol at 197.53°K. The calculated entropy from this table is also 64.54 eu. The range in values of I_AI_BI_C corresponds to an entropy change of ± 0.022 eu.

Sept. 30, 1965; June 30, 1969

Vibrational Frequencies and Degeneracies

ω_1, cm^{-1}	ω_2, cm^{-1}	ω_3, cm^{-1}
1228 (1)	1117 (1)	376 (2)
807 (1)	714 (1)	1251 (2)
348 (1)	1243 (2)	573 (2)
Torsion	619 (2)	220 (2)

Bond Distances: C-F = 1.32 Å C-C = 1.56 Å
Bond Angle: C-C-F = 109.5 ± 1.5°
Product of the Moments of Inertia: I_AI_BI_C = 6.007 × 10⁻¹¹³ g³ cm⁶
Reduced Moment of Inertia: I_{red} = 7.32 × 10⁻³⁹ g cm²
Barrier to Internal Rotation: V = 3.96 kcal/mol

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF₃, CF₃X (X = H, Cl, Br, I, CF₃) and C₂F₄. Details of the input data and the adjustment are given in (1). Data pertinent to C₂F₆ are summarized below. Calorimetric data (2) for the reaction of C₂F₆ with potassium were omitted from the adjustment due to insufficient characterization of the products.

Source	Method	Reaction	ΔH ₂₉₈ ^a kcal/mol
(2)	Calorimetric	3C ₂ F ₆ (g) + 2NF ₃ (g) → 6CF ₃ (g) + N ₂ (g)	-311.6 ± 3.0
(2)	Calorimetric	2C ₂ F ₆ (g) + 6NF ₃ (g) → 6CF ₃ (g) + 4N ₂ (g)	-321.3 ± 1.2
(4)	Equilibrium	2C ₂ F ₆ (g) + C ₂ F ₄ (g) → C ₂ F ₈ (g)	-824.4 ± 0.6
(5)	Equilibrium	C ₂ F ₆ (g) + Br ₂ (g) → 2CBrF ₃ (g)	-322.2 ± 1.8
(6, 5)	Kinetic	C ₂ F ₆ (g) + 2CF ₃ (g)	3.30 ± 0.7
			97.6 ± 6

Heat Capacity and Entropy

The adopted molecular structure was derived from electron-diffraction data by Swick and Karle (8). The vibrational frequencies are from the assignment of Carney et al. (9), who reviewed the extensive spectral data. Shimanouchi (10) has selected the same frequencies. Low-temperature calorimetric data were used by Pace and Aton (11) to derive a value for the entropy of the ideal gas of 69.88 ± 0.20 gibbs/mol at 194.87°K. This value is used to fix the barrier to internal rotation at 3960 cal/mol. Thermodynamic functions are calculated from these parameters, using hindered internal rotation in place of a torsional vibration.

An uncertainty of ±0.2 gibbs/mol in the third-law entropy corresponds to a variation in the barrier to internal rotation of about ±700 cal/mol. This range easily includes the barrier of 4300 cal/mol derived by Karle (12) from analysis of the electron-diffraction data (8). Uncertainty in the entropy of this table should not exceed 0.5 gibbs at 1000°K.

Heat of Formation

The heat of formation of C₂H(g) is not well established; however, we can place reliable upper and lower limits on the value.

T. L. Cottrell, "The Strengths of Chemical Bonds," 2nd Ed., Academic Press, New York, 1958, gives an upper limit for the C-H bond dissociation energy in acetylene, D(HCC-H) 4121 kcal. This was obtained from the fact that ultraviolet light of 121 kcal/mol energy causes acetylene to form diacetylene and hydrogen; assuming that this process occurs through the CCH radical, the light energy is equated with D(HCC-H). This value of D(HCC-H) gives an upper limit for ΔH_f^o298(CCH,g) 4123 kcal/mol.

A lower limit for D(HCC-H) is obtained from a consideration of the C-H bond dissociation energies in ethylene and ethane, D(C₂H₃-H) = 103 kcal and D(C₂H₅-H) = 98 kcal. The heats of formation of the C₂H₃ and C₂H₅ radicals and their parent compounds are taken from S. W. Benson, J. Chem. Educ. 42, 502 (1965). The vibrational frequency of the C-H stretch increases steadily from ethane to ethylene and acetylene. Similarly we expect the bond strength to increase, and so D(HCC-H) > 103 kcal; this yields ΔH_f^o298(CCH,g) > 105 kcal/mol.

F. H. Coats and R. C. Anderson, J. Am. Chem. Soc. 79, 1340 (1957), obtained several values for ΔH_f^o298(CCH,g) from mass-spectroscopic measurements; their values range from 110 kcal/mol to 153 kcal/mol, but they chose to adopt 112 ± 3 kcal/mol.

Our adopted value of ΔH_f^o298(CCH,g), 114 ± 7 kcal/mol, is 2 kcal smaller than that estimated by W. Tsang,

S. H. Bauer and M. Comperthwaite, J. Chem. Phys. 35, 1768 (1962).

Heat Capacity and Entropy

The molecule is assumed to be linear; the bond lengths are assumed to be the same as in acetylene and were taken from L. E. Sutton, "Interatomic Distances Supplement," Special Publication No. 18, The Chemical Society, London, 1965.

The vibrational frequencies are those estimated by M. N. Flooster and T. B. Reed, J. Chem. Phys. 31, 66 (1959). It should be noted that the values of the free energy function given by Flooster and Reed are incorrect due to the neglect of the electronic contributions.

The electronic levels, x²Σ⁺ and a²Π_g, were estimated by analogy with those of CN(g) which is isoelectronic; this assumption holds very well in the parent molecules HCC and HCN (O. Herzberg, "Electronic Spectra and Electronic Structure of Polyatomic Molecules," D. Van Nostrand Co., New York, 1966). The molecule C₂H₂⁺, which is also isoelectronic with CCH, is predicted to have a ²Π ground state by Herzberg, loc. cit.

Dec. 31, 1968

Heat of Formation
 The value of $\Delta H_f^\circ = 51.1 \text{ kcal/mol}$ is calculated from the estimated $\Delta H_f^\circ = -53 \pm 10 \text{ kcal/mol}$ for $\text{HCCl(g)} + \text{Cl}_2(\text{g}) + \text{CHCl}_3(\text{g})$, using $\Delta H_f^\circ(\text{CHCl}_3(\text{g})) = -1.86 \text{ kcal/mol}$ (1). The value of ΔH_f° is assumed to be the same as that for the reaction $\text{HCCl(g)} + \text{Cl}_2(\text{g}) + \text{CHCl}_3(\text{g})$, using $\Delta H_f^\circ(\text{C}_2\text{H}_2, \text{g}) = 54.19 \text{ kcal/mol}$ (1) and $\Delta H_f^\circ(\text{CHCl}_3(\text{g})) = 1.2 \text{ kcal/mol}$ (2).

Heat Capacity and Entropy

The linear molecular structure and bond distances were determined from the microwave spectrometrical studies by Tyler and Sheridan (3). Their results are in good agreement with those of Westenberg, Goldstein and Wilson (4). The principal moment of inertia is $1.48361 \times 10^{-38} \text{ g cm}^2$.

The vibrational frequencies were observed in the infrared spectra by Hunt and Wilson (5), and Richardson and Goldstein (6).

Heat of Formation

The heat of formation is estimated by assuming that the C-C bond strength is the average of those in C_2F_2 (113 kcal) and C_2H_2 (229 kcal). Combining the average value (171 kcal) with the heats of formation of CF and CH from the JANAF Tables, yields $\Delta H_f^\circ(C_2HF, g) = 30 \pm 15 \text{ kcal/mol}$.

Heat Capacity and Entropy

G. R. Hunt and M. K. Wilson, J. Chem. Phys. 34, 1301 (1961), and J. K. Brown and J. K. Tyler, Proc. Chem. Soc. (London) 1961, 13 (1961), have reported the infrared spectrum and have assigned the fundamental frequencies. The frequencies used in the present table are median values of the two sets and are generally within 5 cm^{-1} of each set.

The molecule has been shown to be linear by J. K. Tyler and J. Sheridan, Trans. Faraday Soc. 59, 2661 (1963), who reported the rotational constant B_0 .

The electronic ground state is assumed to be $^1\Sigma$ by analogy with C_2H_2 .

Heat of Formation

Taken from D. D. Wagman, J. E. Kilpatrick, K. S. Pitzer, and P. D. Rossini, J. Research Natl. Bureau Standards 55, 467 (1945).

Heat Capacity and Entropy

J. S. Gordon (private communication, February, 1961) has used the constants listed above to calculate C_p from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954). The constants are from E. E. Ball and H. H. Nielsen, J. Chem. Phys. 18, 1382 (1950) and H. C. Allen, E. D. Tidwell, and E. K. Plyler, J. Research Natl. Bureau Standards 57, 213 (1956). Heat capacities below 298.15°K have been calculated for a rigidly rotating harmonic oscillator.

Heat of Formation.

The heat of combustion of ethylene was measured by F. D. Rossini and J. W. Knowlton, *J. Res. Natl. Bur. Std.* **19**, 249 (1937). From the value, ΔH_f° 298.15 = -337.28 ± 0.07 kcal. mole⁻¹ for the reaction C₂H₄(g) + 3 O₂(g) = 2 CO₂(g) + 2 H₂O(l), the heat of formation (ΔH_f° 298.15) for C₂H₄(g) was derived to be 12.54 ± 0.07 kcal. mole⁻¹. The values of ΔH_f° 298.15 for CO₂(g) and H₂O(l) used for calculation were obtained from F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine, and Irving Jaffe, "Selected Values of Chemical Thermodynamic Properties", Circular of the National Bureau of Standards 500, 1952.

Heat Capacity and Entropy.

The molecular structure, bond distances and angles were obtained from H. C. Allen, Jr. and E. K. Plyler, *J. Am. Chem. Soc.* **80**, 2673 (1958). The vibrational frequencies were taken from W. L. Smith and I. M. Mills, *J. Chem. Phys.* **40**, 2095 (1964). Eight of the twelve frequencies were reported by R. L. Arnett and B. L. Crawford, *J. Chem. Phys.* **19**, 118 (1950); B. L. Crawford, J. E. Lancaster and R. Inskip, *J. Chem. Phys.* **21**, 678 (1953); B. F. Stocherff, *J. Chem. Phys.* **21**, 755 (1953); T. Feldman, J. Romanko and H. L. Welsh, *Can. J. Phys.* **34**, 737 (1956); and H. C. Allen and E. K. Plyler, loc. cit. O. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., New York, 1945, also reported the vibrational frequencies for ethylenes as 3019.3 (1), 1623.3 (1), 1342.4 (1), 825.0 (1), 3272.3 (1), 1050 (1), 949.2 (1), 943 (1), 3105.5 (1), 995 (1), 2989.5 (1) and 1443.5 (1) which are very close to the values adopted. The infrared and Raman spectra of ethylene before 1945 have been summarized by O. Herzberg, loc. cit. The molecular structure of ethylene was also determined by L. S. Bartell and R. A. Bonham, *J. Chem. Phys.* **27**, 1414 (1957). Their results, r_{C-H} = 1.085 Å, r_{C-C} = 1.334 Å and X_{H-C-H} = 116° are in excellent agreement with the values adopted. The three principal moments of inertia are I_A = 0.5762 X 10⁻³⁹, I_B = 2.7999 X 10⁻³⁹ and I_C = 3.3761 X 10⁻³⁹ g. cm.²

ΔH_f^o 0 = -9.59 ± 0.15 kcal. mole⁻¹
ΔH_f^o 298.15 = 56.06 cal. deg.⁻¹ mole⁻¹
Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies
 ω , cm.⁻¹ ω , cm.⁻¹

Bond Distances: C-H = 1.0802 Å C-O = 1.4363 Å C-C = 1.4726 Å
Bond Angle: H-C-H = 116° 51' H₂-C-C = 156° 51'
Product of the Moments of Inertia: I_AI_BI_C = 7.42336 X 10⁻¹¹⁶ g.³ cm.⁶

Heat of Formation.

The heat of combustion of ethylene oxide (g) was determined by A. S. Fell and O. Fitcher, Trans. Faraday Soc. 51, 71 (1955) and R. S. Crag and H. Hunt, J. Phys. Chem. 46, 1162 (1942), as -312.15 ± 0.14 and -312.55 ± 0.20 kcal. mole⁻¹, respectively. The corresponding value of ΔH_f^o 298.15 (C₂H₄O, g) was evaluated to be -12.58 ± 0.15 and -12.19 ± 0.22 kcal. mole⁻¹. The former value is adopted.

Heat Capacity and Entropy.

The vibrational frequencies were taken from R. C. Lord and B. Nollin, J. Chem. Phys. 24, 656 (1956). The infrared and Raman spectra of ethylene oxide have also been examined by J. W. Linnett, J. Chem. Phys. 6, 692 (1938) and H. W. Thompson and W. T. Cave, Trans. Faraday Soc., 47, 946 (1951). The vibrational frequencies assigned were slightly different from the ones reported by R. C. Lord and B. Nollin, loc. cit. As a result of analogies between ethylene oxide and ethylene imine, small changes of R. C. Lord and B. Nollin's assignment have been made by W. J. Potts, Spectrochim. Acta, 21, 511 (1965). The bond distances and angles were obtained from O. L. Cunningham, A. W. Boyd and W. D. Omlin, J. Chem. Phys. 17, 211 (1949). The investigation of the structure of ethylene oxide by electron diffraction was reported by P. C. Ackermann and J. E. Mayer, J. Chem. Phys. 4, 377 (1936) and M. Igereahi, Bull. Chem. Soc. Japan, 28, 330 (1953). The three principal moments of inertia are: I_A = 3.8052 X 10⁻³⁹, I_B = 3.2788 X 10⁻³⁹ and I_C = 5.9499 X 10⁻³⁹ g. cm.²

The calculated heat capacities (307.2 - 371.2°K.) are in good agreement with the experimentally measured ones reported by O. B. Kistiakowsky and W. W. Rice, J. Chem. Phys. 9, 616 (1940).

POTASSIUM CYANIDE, DIMERIC ((KCN)₂)

Bond Distance: K-C = [2.75] Å C-N = [1.16] Å

Bond Angle: N-C-K = [140]° C-K-C = [100]° K-C-K = [80]°

Product of the Moments of Inertia: $I_A I_B I_C = [2.94818 \times 10^{-112}] \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

$\Delta H_f^\circ 298.15 ((\text{KCN})_2, g)$ was calculated based on an estimated heat of dissociation, 40 kcal. mole⁻¹ for the reaction $(\text{KCN})_2(g) \rightarrow 2\text{KCN}(g)$, which was obtained by comparison with that for $(\text{NaCN})_2(g)$.

Heat Capacity and Entropy.

The molecular structure and bond angles were assumed to be the same as those for KCN(c) reported by J. M. Bljvoet and J. A. Lely, Rec. trav. chim. 52, 908 (1940). The C-N bond distance was assumed to be the same as that for KCN(g), and the K-C bond distance was assumed to be 10% longer than that in KCN(g). The vibrational frequencies were estimated by comparison with those for K₂P₂(g). The last six frequencies were adopted from the bending and asymmetric stretching frequencies for KCN(g). The three principal moments of inertia are: $I_A = 4.05745 \times 10^{-38}$, $I_B = 6.73551 \times 10^{-38}$ and $I_C = 1.079095 \times 10^{-37} \text{ g. cm.}^2$.

Heat of Formation.

A. J. Merer and D. N. Trevis, Can. J. Phys. 44, 353 (1966), state that the observed bond length in CNC(g) indicates double-bonded CN links. The value of the C = N dissociation energy is derived as 147 kcal from the heat of combustion of n-butyl-isobutylidene emine determined by O. E. Coates and L. E. Sutton, J. Chem. Soc. 1187, (1948). However, due to possible extra binding energy from the unpaired electron, we assume here a slightly higher value of 160 kcal. This yields a ΔHf°₂₉₈(CNC,g) = 133 kcal/mol. It is also possible to calculate another value by assuming that the ratio of the heat of atomization (ΔH_{at}) of Si₂N to that of C₂N(g) is equal to the ratio of the dissociation energies of SiN(g) and CN(g); by this method ΔHf°₂₉₈(CNC,g) = 144 kcal/mol.

Heat Capacity and Entropy.

Merer and Trevis, loc. cit., have observed the ultraviolet absorption spectrum of the CNC radical. They have assigned the configuration, bond distance, and the electronic levels. In addition, they have derived w₀, the remaining frequencies are estimated by comparison with the T₀ state of C₂(g), which has been assigned by N. Welnir and D. J. McLeod, J. Chem. Phys. 40, 1305 (1964), and J. Chem. Phys. 45, 3096 (1966).

214.9 (1)
507.2 (2)
240 (2)

Rotational constant B₀ = 0.15752 ± 0.00015 cm.⁻¹ CN distance = 1.157 Å CC distance = 1.380 Å σ = 2
 Moment of inertia = 1.776(g) × 10⁻³⁸ g. cm.²

Heat of Formation

J. W. Knowlton and E. J. Prosen, J. Research Natl. Bur. Standards 46, 489 (1951), report ΔH°_f 298.15 = -261.94 ± 0.43 kcal. for the reaction C₂N₂(g) + 2 O₂(g) → 2 CO₂(g) + N₂(g). When corrected for a change in the atomic weight of carbon, this becomes ΔH°_f 298.15 = -261.95 ± 0.43 kcal., whence ΔH°_f 298.15 for C₂N₂(g) is found to be 73.87 ± 0.43 kcal. mole⁻¹.

Heat Capacity and Entropy

A. Langseth and C. K. Møller, Acta Chem. Scand. 4, 725 (1950), determined the vibrational frequencies by Raman spectroscopy. C. K. Møller and B. P. Stoicheff, Can. J. Phys. 32, 625 (1954), determined B₀ by Raman spectroscopy and calculated the bond lengths listed above. These agree with lengths found from electron-diffraction measurements by Langseth and Møller, loc. cit., (CN distance = 1.15 Å, CC distance = 1.38 Å) and L. Pauling, H. D. Springall, and K. J. Palmer, J. Am. Chem. Soc. 61, 927 (1939) (CN distance = 1.16 ± 0.02 Å, CC distance = 1.37 ± 0.02 Å). From measurements reported by R. A. Ruehrwein and W. F. Glauque, J. Am. Chem. Soc. 81, 2940 (1959), S°_{298.15} is calculated by the third law to be 57.63 cal. deg.⁻¹ mole⁻¹, in satisfactory agreement with the value calculated here.

Heat of Formation.

The mass spectra of vapors from samples of NaCN have been observed by R. F. Porter, J. Chem. Phys. **35**, 318 (1961), at temperatures around 1000°K. The results indicate that the compound evaporates as NaCN(g) and Na₂(CN)₂(g). A comparison of relative ion currents produced by electron bombardment of NaCN vapors effusing from single - and double-oven-type Knudsen cells, yielded information on the partial pressures of monomer and dimer. Based on the partial pressures for NaCN(g) and (NaCN)₂(g) reported at temperatures, 903-1049°K., the vapor pressures of (NaCN)₂(g) over NaCN(l), 1078.2-1266.2°K., were calculated from the total vapor pressure measurements reported by C. K. Ingold, J. Chem. Soc. **123**, 885 (1923). By the second and third law methods, the values of ΔH°_f 298.15 (1 → dimer) were evaluated to be 38.89 and 38.21 kcal. mole⁻¹, respectively. Using the third law value, the heat of formation for (NaCN)₂(g) was evaluated.

Heat Capacity and Entropy.

The molecular structure, bond distances and C-Na-C bond angle were estimated by R. F. Porter, loc. cit. The vibrational frequencies were estimated by comparison with those for NaCl(g). The last six frequencies were the bending and asymmetric stretching frequencies for NaCN(g). The three principal moments of inertia are: I_A = 1.3570 X 10⁻³⁸, I_B = 5.1030 X 10⁻³⁸ and I_C = 6.4860 X 10⁻³⁸ g. cm.²

Heat of Formation

The adopted heat of formation, $\Delta H^{\circ}_{f,298.15}$ (C₂O, g) = 68.5 kcal/mol, was calculated from the heat of reaction $\Delta H^{\circ}_{f,298} = 65.5$ kcal/mol for C₂O₂(g) = C₂O(g) + CO(g) using all JANAF functions (dated Sept. 30, 1965). The value of $\Delta H^{\circ}_{f,298}$ was obtained from the third law calculation of the equilibrium constant (K_p = 3.3 x 10⁻⁶ atm at 1060°K) which was determined in the studies of decomposition rate of C₂O₂(g) by H. B. Palmer and W. D. Cross, Carbon 3, 475 (1966).

M. E. Jacox, D. E. Milligan, N. G. Moll, and W. E. Thompson, J. Chem. Phys. 43, 3745 (1965), have observed the photo-dissociation of C₂O near 5000 Å, which corresponds to a minimum of 57 kcal/mol for C₂O(g) → C(g) + CO(g). This yields $\Delta H^{\circ}_{f,298}$ (C₂O, g) ≤ 87 kcal/mol, which was not adopted because the irradiation was not monochromatic and thus possibly contained all wavelengths below 5000 Å.

Heat Capacity and Entropy

Jacox et al., loc. cit., have observed three vibrational fundamentals in the infrared spectrum by matrix isolation, and suggested a linear structure with 3 Σ ground state for the CCO radical (g). They also estimated the bond distances C-C = 1.160 Å and C-O = 1.279 Å based on the structural analogy between the carbon suboxide and the CCO radical. The principal moment of inertia is 8.825 x 10⁻³³ g cm². K. D. Bayes, J. Am. Chem. Soc. 85, 1730 (1963), has predicted that the Λ and Σ states lie respectively 0.5 and 0.8 eV above the ground state. These two electronic states have been included in the tabulation.

Bond Angle: C-C-Si = 180°

Rotational Constant: B₀ = [0.2012] cm⁻¹

Heat of Formation.

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibria over the systems SiC-graphite¹, SiC-silicon² and boron-carbon-silicon³. Third law analysis of the partial pressures of C₂Si and Si lead to the concordant values 146.7, 149.0 and 146.0 kcal/mol. Although the drifts all suggest that the entropy of C₂Si may be about 3.5 eu less than tabulated, this is of doubtful significance because the uncertainty bands are so large. The low condensation coefficient suggested by Drowart⁴ may also be involved. Rates of free evaporation reported by Voronin⁴ lead to apparent pressures which are smaller by a factor of 1/30, thus confirming the existence of a low evaporation coefficient. The adopted value of ΔH°₂₉₈ = 147 ± 7 kcal/mol includes allowance for the unlikely possibility that the entropy may be in error by up to 3.5 eu.

Source	Method	Reaction	Range, T°K	No. of Points	ΔH° ₂₉₈ (kcal/mol)	Drift (eu)	ΔH° ₂₉₈ (kcal/mol)
Drowart (1958)	"	A	2149-2316	7	31±9	36.98	146.7

B) 2SiC(α) = Si(l) + C ₂ Si(g)							

Heat Capacity and Entropy.

The known molecular constants are from the assignments of Walther and McLeod⁵. These authors observed the infrared spectrum, emission spectrum and visible absorption spectrum of C₂Si in matrix isolation. The matrix data allowed more certain assignment of the A-X band system of the gas as observed by Klean⁶ and McKellar⁷. Walther concluded that this system probably involves transitions between a ¹Σ⁺ ground state and a ¹Π excited state. The two stretching frequencies were observed in the matrix infrared spectrum, whereas the bending mode, 300 cm⁻¹, was derived solely from the analysis of the A-X band system. The analysis presumed a linear unsymmetrical structure for the molecule.

A ³Π excited state is assumed to lie 7000 cm⁻¹ below the ¹Π state, which presumably arises from the same molecular orbital configuration. The effect of the estimated level is to increase the entropy by about 0.2 and 1.8 eu at 3000 and 6000°K. Bond distances are estimated by comparison with those in Si₂, C₂ and C₃. The moment of inertia is 13.91 × 10⁻³⁹ g cm².

Vibrational Frequencies and Degeneracies

ω_i , cm ⁻¹	
1225 (1)	
615 (2)	
2040 (1)	

The contribution of the doubly degenerate bending frequency was approximated by direct summation of the following levels (cm⁻¹): 0, 63.5, 132.7, 207.4, 286.5, 370.5, 459.2, and 650 x n where n = 1 to 76. The contribution to each function due to these levels was doubled to account for the degeneracy.

Bond Distance: C-C = 1.277 Å

Bond Angle: C-C-C = 180°

σ = 2

Rotational Constant: B₀ = 0.4305 cm⁻¹

Heat of Formation

Drowart et al. (1) have measured mass spectrometrically the ion intensity ratio C₃⁺/C⁺ as a function of temperature from 1800 to 2700°K. We derive from a 2nd law analysis of their data ΔH_{f,2000} = 185.2 ± 3.3 kcal, and S₂₀₀₀ = 74.9 ± 2.8 eu by calculation of the absolute pressure from the vapor pressure of monatomic carbon and a relative ionization cross-section ratio of 2.3. The entropy uncertainty includes 1.3 eu for uncertainty in the absolute pressure. Several earlier mass-spectrometric determinations (2, 3, 4) are in reasonable agreement. The absolute magnitude of the pressure is also confirmed by the work of Thorn and Winslow (5) who measured the total pressure of all species over graphite as 1.2 to 4.8 x 10⁻⁷ atm. at 2400°K.

Subtracting the JANAF values for C and C₂ we obtain C₃ = 5.4 x 10⁻⁸ to 2.2 x 10⁻⁷ atm., which compares with Drowart's value of 3.3 x 10⁻⁸ to 1.3 x 10⁻⁷ atm. The 2nd law heat of formation is reported (3) to be ΔH₂₄₀₀ = 184.4 but the range is only 80°K. It does, however, confirm the magnitude of the mass-spectrometric values for both heat and entropy. We have adopted a heat of formation within the uncertainty limits of Drowart's measurements which with the adopted functions yields pressures in the 2000-3000°K range consistent with the measurements. We were not able to generate functions which agree exactly with the 2nd law entropies, since even direct summation over only the observed levels of the bending frequency gives an entropy which is already too large.

Heat Capacity and Entropy

The stretching frequencies are from Merer (6), Weltner et al. (7) and Weltner and McLeod (8). The bending frequency and its harmonics are from Gausset et al. (9) and Merer (6). The rotational constant and bond distance are from Gausset et al. (9).

As indicated briefly above, the calculated entropy of C₃ gas is higher than the experimental value even when a summation is performed only over the observed first six levels of the bending frequency. Treatment of the vibration as a harmonic oscillator or as an anharmonic oscillator gives values considerably higher. Strauss and Thiele (10) have also calculated functions based on a quartic potential function which still yields values several units higher than the experiments. In order to reduce the entropy to the approximate range of the measurements we have made the assumption that the potential function is of an unusual form above the sixth vibrational level. We assume that the large amplitude of the bending vibration causes a drastic change in the function, possibly due to the increasing repulsion between carbon atoms, as the amplitude increases. Thus, we assume a very steeply rising potential above the sixth vibrational level. We have chosen to represent this part of the potential by a harmonic oscillator of 650 cm⁻¹. The choice of 650 cm⁻¹ is arbitrary, but is not unreasonable for a bending vibration, and yields functions which approximate the experimental data.

In order to explain the observed spectrum of C₃O, a molecule with a bending frequency of 63 cm⁻¹, Smith and Barrett (11) have proposed that potential maxima occur in the bending potential away from linearity. Thus, the adoption of an unusual potential function for C₃ bending may be justifiable. We do not claim that our functions are necessarily correct but only that they include all known facts and satisfy the experimental equilibrium observations. Further investigation of the carbon vapor pressure and of the higher vibrational levels of C₃ is desirable.

$$\Delta H_f^0 = -50.35 \pm 1.6 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 298.15 = -51.55 \pm 1.6 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = \text{Unknown}$$

$$S_{298.15} = 21.26 \pm 0.3 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = [2500]^\circ \text{K.}$$

Heat of Formation.

The $\Delta H_f^0 298.15 = -51.55 \pm 1.6 \text{ kcal. mole}^{-1}$ is the average value of $\Delta H_f^0 298.15 = -49.7 \pm 1.2 \text{ kcal. mole}^{-1}$ by R. C. King and G. T. Armstrong, National Bureau of Standards Report No. 8504 (1964) and that of $\Delta H_f^0 298.15 = -53.4 \pm 2.0 \text{ kcal. mole}^{-1}$ by A. D. Mah, United States Bureau of Mines, Report No. 6415 (1964). Both measured the heat of reaction $\text{Al}_4\text{C}_3(\text{c}) + 6\text{O}_2(\text{g}) \rightarrow 2\text{Al}_2\text{O}_3(\text{c}, \infty) + 3\text{CO}_2(\text{g})$ and used their $\Delta H_f^0 298.15$ and the $\Delta H_f^0 298.15$ of $\text{Al}_2\text{O}_3(\text{c})$ and $\text{CO}_2(\text{g})$ to calculate the $\Delta H_f^0 298.15$ of $\text{Al}_4\text{C}_3(\text{c})$. The $\Delta H_f^0 298.15$ measured by King and Armstrong was $-1033.3 \pm 1.1 \text{ kcal. mole}^{-1}$, the $\Delta H_f^0 298.15$ measured by Mah was $-1029.6 \pm 1.9 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The low temperature heat capacities, 18-390°K., were measured by W. G. Saba and G. T. Furukawa, National Bureau of Standards Report 7587, July 1, 1962. The high temperature heat capacities, 275-1173°K., were measured by A. C. Victor, W. R. Thurber, and T. B. Douglas, National Bureau of Standards Report 7437, January 1, 1962. These two sets of heat capacity data were joined smoothly and extrapolated to 2000°K. by W. G. Saba and G. T. Furukawa, loc. cit. The values of C_p above 2000°K. were estimated by extrapolation graphically. $S_{298.15}$ was reported by W. G. Saba and G. T. Furukawa, loc. cit., using $S_{298.15}^0(\text{extrap.}) = 0.013 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Temperature.

T_m was estimated by O. Ruff and E. Jellinek, Z. anorg. u. allgem. Chem. 97, 312 (1916).

Heat of Formation

Kybett et al. (1) have determined the heat of combustion of the liquid form under its own pressure using the sample from the heat capacity determinations (2).

The average of four determinations gave $\Delta H^\circ_{298}(l)$ = -28.03 ± 0.24 kcal/mol; the authors report -29.03 due to an arithmetic error. The sample was 99.98 mole percent pure. McDougall et al. (2) measured $\Delta H^\circ_{298}(g)$ = 6.421 ± 0.012 kcal/mol from which we calculate $\Delta H^\circ_{298}(g)$ = 5.65 ± 0.2 kcal/mol. Thus the heat of formation of the gas is found to be -22.38 ± 0.44 kcal/mol.

Heat Capacity and Entropy

There has been considerable controversy as to the configuration of this molecule and the assignment of its vibrational frequencies. However, the evidence seems fairly conclusive for the linearity of the molecule from the work of Lafferty et al. (3) and Miller et al. (4). The rotational constant adopted here is that found by Lafferty et al. (3) and the vibrational frequencies are those reported by Miller et al. (4), except for ν_7 which is taken from Miller et al. (5) and Borgers (2). The low frequency ν_8 mode is confirmed by the work of McDougall et al. (2), who measured the low temperature entropy of C₃O₂(c) and (l) and also the heat of vaporization. From a comparison of the entropy calculated statistically and that measured, they conclude ν_7 = 63.2 cm⁻¹. The values adopted are confirmed by third law analysis of the vapor pressure data of McDougall et al. (5) which indicate a heat of vaporization in fair agreement with their calorimetric value. The drift in the third law analysis indicates that the entropy of the solid is too low or that of the gas is too high by 1 eu. Alternatively as systematic error in the pressure measurements could have caused this deviation.

The bond distances are taken from the electron diffraction experiments of Livingston et al. (6) and are in good accord with the adopted rotational constant.

Heat of Formation

The heat of formation is obtained from the mass-spectrometric results of Drowart et al. (1) who obtained ΔH°₂₄₀₀ = 226 ± 7 kcal/mol. This was obtained from a 2nd law analysis of the ion intensity ratio C₄⁺/C⁺ over a temperature range of 2200-2700°K. The absolute pressure, obtained from a knowledge of the monatomic carbon vapor pressure and an estimated ionization cross-section ratio of 4.96, yields a 2nd law entropy at 2400°K of 90.5 ± 3 eu. The uncertainty in the ionization cross-section ratio is probably no more than a factor of two which gives an overall entropy uncertainty of 4.5 eu. The heats of formation at temperatures other than 2400°K depend on the functions adopted, for a discussion of these see below.

Heat Capacity and Entropy

The molecular properties of C₄ are all estimated. We have chosen a set of functions which is consistent with the mass-spectrometric observations of Drowart et al. (1). The thermodynamic functions of C₄ were first estimated by Pitzer and Clementi (2) but the basis for this estimate has completely changed. Originally they were calculated by analogy with C₃, C₃O₂ and CO₂, but the discovery of very low bending frequencies in C₃ and C₃O₂ complicated the picture by raising the calculated entropies significantly. Sandborn (3) has correlated the bending force constants in several related triatomics and has estimated the vibrational frequencies in C₄ and C₅. These vibrational frequencies yield high entropies outside the limits of the second law determination. Since these frequencies are estimates based on a basically triatomic correlation we have chosen to adopt two bending frequencies of 550 cm⁻¹ rather than the 200 cm⁻¹ and 440 cm⁻¹ estimated by Sandborn. In addition we have assumed that the ground state arising from a π² term is ¹Σ and not ³Σ as assumed by Pitzer and Clementi. The basis for both these changes is to make the functions conform to the only available measured data. Use of the present table will yield values for the vapor pressure of C₄ in excellent agreement with the measurements in the 2000-3000°K range. Outside this range they provide only a general indication of the variation since they may not correspond to the real situation.

The stretching frequencies are from Sandborn (3) and the bond length is estimated from C₃.

Heat of Formation

O. T. Armstrong and S. Marantz, J. Phys. Chem. **64**, 1776 (1960), measured the heat of combustion of the liquid for which they obtain a ΔH_f⁰ of 120.6 kcal. mole⁻¹ using 94.05 kcal. mole⁻¹ for ΔH_f⁰ of CO₂(g). They calculate the ΔH_f⁰ of 298.15 of C₄N₂(g) with a ΔH_{vap} taken from A. J. Saggio, J. Org. Chem. **22**, 1171 (1957).

Heat Capacities and Entropies

Bond lengths determined by P. A. Miller and R. B. Hannan Jr., J. Chem. Phys. **21**, 110 (1953) from X-ray diffraction measurements on the solid. The vibrational frequencies were observed in the infra red and Raman by F. A. Miller, R. B. Hannan Jr., and L. R. Cousins, J. Chem. Phys. **23**, 2127 (1955).

Heat of Formation

The heat of formation is obtained from the mass-spectrometric results of Drowart et al. (1) who obtained $\Delta H_f^\circ = 230 \pm 5 \text{ kcal/mol}$. This was obtained from a 2nd law analysis of the ion intensity ratio C_5^+/C^+ over a temperature range of 2200-2700°K. The absolute pressure, obtained from a knowledge of the monatomic carbon vapor pressure and an estimated ionization cross-section ratio of 6.3, yields a 2nd law entropy at 2400°K of $103.7 \pm 2 \text{ eu}$. The uncertainty in the ionization cross-section ratio is probably no more than a factor of two which gives an overall entropy uncertainty of $\pm 3.5 \text{ eu}$. The heats of formation at temperatures other than 2400°K depend on the functions adopted, for a discussion of these see below.

Heat Capacity and Entropy

The molecular properties of C₅ are all estimated. We have chosen a set of functions which is consistent with the mass-spectrometric observations of Drowart et al. (1). The thermodynamic functions of C₅ were first estimated by Pitzer and Clementi (2) but the basis for this estimate has completely changed. Originally they were calculated by analogy with C₄, C₃O₂ and CO₂, but the discovery of very low bending frequencies in C₄ and C₃O₂ complicated the picture by raising the calculated entropies significantly. Sandborn (3) has correlated the bending force constants in several related triatomics and has estimated the vibrational frequencies in C₄ and C₅. These vibrational frequencies yield high entropies outside the limits of the second law determination. Since these frequencies are estimates, based on a basically triatomic correlation we have chosen to adopt three doubly degenerate bending frequencies of 550 cm⁻¹ in place of the 130 cm⁻¹, 330 cm⁻¹ and 520 cm⁻¹ frequencies estimated by Sandborn. The basis for this change is to make the functions conform to the only available measured data. Use of the present tables will yield values for the vapor pressures of C₄ in excellent agreement with the measurements in the 2000-3000°K range. Outside this range they provide only a general indication of the variation since they may not correspond to the real situation.

The stretching frequencies are from Sandborn (3) and the bond length is estimated equal to that in C₃.

Heat Capacity and Entropy

The low temperature heat capacity data of Griffel et al. (1), 1.8° to 4.2°K, Roberts (2), 1.5° to 20°K, and Clusius and Vaughan (3), 10° to 200°K, were fit with polynomial expressions. Up to 20°K the three sets fit the adopted curve within ± 61 with a maximum deviation of 14%. This is considered excellent agreement since the heat capacity is only 0.35 gibbs/mol at 20°K. From 20° to 200°K the data of Clusius were within $\pm 1\%$ of the adopted polynomial. The data of Gunther (4), 22° to 62°K, generally deviated from the adopted curve by 10%. The polynomial fit of the data of Clusius was arranged to be linear in temperature at high temperatures and was extrapolated to 298°K. The data of Eastman et al. (5), 67° to 293°K, were consistently high by 5.8 to 91 over the whole range. The extrapolation of the heat capacity to 6.28 gibbs/mol at 298°K is further justified by comparison with the heat capacity of magnesium, which is almost identical to that of calcium over the whole range, if its temperature scale is multiplied by 0.75.

The heat capacity between 298° and 721°K was obtained by forcing a polynomial of the type $H = aT^2 + bT + c + d/T$ through 298° with a slope of 6.28 and also through a value of $H_{721} = 2736$ cal, and making a good fit of the adopted low temperature enthalpies. The choice of $H_{721} = 2736$ cal was made, since Zalesinski and Zulinsky (6), Jauch (7), and Eastman et al. (8) were in essential agreement in the beta-phase at this temperature. The enthalpy of transition was subtracted to give the adopted value. The individual measurements of Jauch (7) were not available, but the value at 720°K could be read from a small plot with reasonable accuracy; Eastman et al. (8) gave only an equation for their data. There is no question that reliable measurements of the heat capacity and enthalpy are needed in the range 200° to 700°K.

Transition Data

The temperature of transition was that reported by Peterson and Fattore (9) and confirmed by Chiotti et al. (10). Earlier reports on impure specimens ranged from 718° to 737°K and were not considered. The heat of transition was measured by Chiotti et al. (10) using an adiabatic high temperature calorimeter, and is in agreement with that reported by Kubaschewski (11) of 0.24 ± 0.04 kcal from enthalpy data.

Sublimation Data

See Ca(g) for details.

CALCIUM, BETA (Ca)

(CRYSTAL)

GFW = 40.08

 ΔH°_f = unknown $\Delta H^\circ_{f, 298.15} = 10.15 \text{ gibbs/mol}$ $\Delta H^\circ_t = 0.220 \pm 0.05 \text{ kcal/mol}$ $\Delta H^\circ_m = 2.04 \pm 0.10 \text{ kcal/mol}$ $S^\circ_{298.15} = 10.15 \text{ gibbs/mol}$ $T_t = 721 \pm 2^\circ\text{K}$ $T_m = 1112 \pm 2^\circ\text{K}$

Heat of Formation

Obtained from that of α -Ca by adding ΔH°_t and the difference in $H^\circ_{721} - H^\circ_{298}$ for α - and β -Ca.

Heat Capacity and Entropy

The enthalpy at 721°K was fixed as described on the α -Ca table. The data of Jauch (1), and Zalesinski and Zulinski (2), and Eastman et al. (3) were then fitted by an equation of the form $H = a + bT + cT^2$ where $a = -1315$, $b = 4.014$ and $c = 0.00285$. The values of Jauch, read from a small graph, fit within 1% generally and within 2% maximum deviation; those of Zalesinski and Zulinski fit within 0.7% with the exception of the highest point which differed by 1.8%. The data of Eastman et al. vary from 3.6% high to 0.4% low. The entropy was obtained in a manner analogous to the heat of formation.

Transition Data

See the α -Ca table for details.

Melting Data

The melting point is that reported by Peterson and Fattore (4) and confirmed by Chioffi et al. (5). Earlier reports on less pure specimens ranged from 1083° to 1122°K . The heat of melting was measured by Chioffi et al. (5) using an adiabatic high temperature calorimeter, and is in agreement with that reported by Kubaschewski (6) of $2.07 \pm 0.1 \text{ kcal/mol}$ from enthalpy data.

Ca

Calcium (Ca)

(Liquid)

GFW = 40.08

CALCIUM (Ca)

(LIQUID)

GFW = 40.08

$$S_{298.15}^{\circ} = 12.105 \text{ gibbs/mol}$$

$$\Delta H_f^{\circ} 298.15 = 2.606 \pm 0.1 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 2.04 \pm 0.10 \text{ kcal/mol}$$

$$T_m = 1112 \pm 2^{\circ}\text{K}$$

$$\Delta H_v^{\circ} = 36.9668 \text{ kcal/mol}$$

$$T_b = 1767.4 \pm 15^{\circ}\text{K}$$

Heat of Formation

Obtained from that of β -Ca by adding ΔH_m° and the difference between $H_{1112}^{\circ} - H_{298}^{\circ}$ for β -Ca and liquid.

Heat Capacity and Entropy

The heat capacity was derived as constant from the enthalpy values of R. Jauch, Diplomarbeit, Techn. Hochschule Stuttgart, 1946, quoted by O. Kubaschewski, Z. Elektrochem. 51, 275 (1950). The entropy was obtained in a manner analogous to the heat of formation.

Melting Data

See the β -Ca table for details.

Vaporization Data

T_b is calculated from the free energy crossovers of the Ca(l) and Ca(g) tables, and ΔH_v° is the difference between $\Delta H_f^{\circ} 1767.4$ for liquid and gas.

The vapor pressure over solid and liquid calcium has been reported by several authors. The results of our analysis of their data are presented in the following table. By using free energy functions based on the α crystal at 298°K all the data yield $\Delta H_{298.15}^\circ$ (Ca, α) which is $\Delta H_{298.15}^\circ$ (Ca, β).

With the exception of sets 2, 4 and 10, all the results for the third law value fall in the range 42 - 43 kcal/mol. The drifts are both positive and negative over solid and liquid, indicating the reliability of the functions within the experimental accuracies. The adopted heat of sublimation, 42.85 $\pm$ 0.3 kcal/mol, is taken as the weighted average of sets 9, 11 and 12 which have drifts less than 1 eu. Note that sets 8 and 9 are in fact the same data but the values in set 8 were read from a graph and initially contained three extra points.

The electronic levels and quantum weights were obtained from Moore (13), and were cut off at 45000 cm⁻¹, which is approximately the ionization limit minus KT for the maximum temperature. All of the unobserved terms in the spectrum are estimated to occur between 47000 cm⁻¹ and the ionization limit.

Heat of Formation

N. D. Potter (1) Investigated mass spectrometrically the gaseous equilibria among Ca, CaCl, and CaCl₂. Ion intensities were measured 2.5 eV above the ionization threshold. Using the equilibrium constants $K = I(\text{CaCl})^2 / I(\text{Ca}) I(\text{CaCl}_2)$ which we calculated from the reported ion intensities for the reaction $\text{Ca(g)} + \text{CaCl}_2(\text{g}) \rightleftharpoons 2\text{CaCl(g)}$ in the temperature range 1252°–1557°K, we obtain $\Delta H_f^\circ_{298} = 15.61 \text{ kcal/mol}$ by the third law method. The third law drift is $-2.8 \pm 3.5 \text{ eu}$. The heat of formation is derived as $\Delta H_f^\circ_{298}(\text{CaCl, g}) = -27.0 \text{ kcal/mol}$.

K. F. Zmbov (2) determined by mass spectrometry the heat of the above reaction as $24.4 \pm 1.3 \text{ kcal/mol}$ with a drift of $12.5 \pm 9.4 \text{ eu}$. This yields the heat of formation, $\Delta H_f^\circ_{298}(\text{CaCl, g}) = -22.7 \text{ kcal/mol}$.

D. L. Hildenbrand (2) also determined the equilibrium constants for the reaction (a) $\text{Ca(g)} + \text{CaCl}_2(\text{g}) \rightleftharpoons 2\text{CaCl(g)}$ and the reaction (b) $\text{Ca(g)} + \text{AlCl}_3(\text{g}) \rightleftharpoons \text{CaCl(g)} + \text{Al(g)}$ by mass spectrometry in the temperature range 1219–1353°K. Third law analysis of the reported equilibrium constants gives $\Delta H_f^\circ_{298} = 21.08 \text{ kcal/mol}$ and drift = $-1.4 \pm 1.8 \text{ eu}$ for reaction (a); and $\Delta H_f^\circ_{298} = 24.20 \text{ kcal/mol}$ and drift = $0.5 \pm 1.3 \text{ eu}$ for reaction (b). From third law $\Delta H_f^\circ_{298}$ of (a) and (b), we derived $\Delta H_f^\circ_{298}(\text{CaCl, g})$ as -24.4 and -23.3 kcal/mol , respectively, using all JANAF functions. Hildenbrand has also derived a corrected $D_0(\text{Ca-Cl}) = 95.0 \text{ kcal/mol}$ from a linear Birge-Sponer extrapolation of the ground state vibrational levels with correction for its ionicity. This corrected $D_0(\text{Ca-Cl})$ yields the heat of formation, $\Delta H_f^\circ_{298}(\text{CaCl, g}) = -23.9 \text{ kcal/mol}$.

Ryabova and Gurvich (3) reported $D_0(\text{Ca-Cl}) = 102 \pm 6 \text{ kcal/mol}$ from flame spectra studies. This leads to

$$\Delta H_f^\circ_{298}(\text{CaCl, g}) = -30.9 \text{ kcal/mol}$$

D. L. Hildenbrand (3) determined the dissociation energy of CaCl₂(g) by electron impact as $D_0(\text{CaCl-Cl}) = 5.04 \pm 0.02 \text{ eV}$ which, combined with JANAF $\Delta H_f^\circ_{298}$ of CaCl₂(g) and Cl(g) gives $\Delta H_f^\circ_{298}(\text{CaCl, g}) = -23.1 \text{ kcal/mol}$.

A weighted average, $\Delta H_f^\circ_{298}(\text{CaCl, g}) = -25 \pm 3 \text{ kcal/mol}$, is adopted in the tabulation.

Heat Capacity and Entropy

The vibrational constants (ω_e and $\omega_e X_e$), electronic levels and ground state configuration were taken from Herzberg (4). Morgan and Barrow (5) made rotational analysis of the $C^2\Pi-X^2\Sigma$ system and reported $B_e = 0.1516 \text{ cm}^{-1}$ and $r_e = 2.439 \text{ \AA}$ for the ground state. The value of q_e is calculated from the Morse potential function. The F and G states were reported by Schutte (6).

Heat of Formation

V. B. Parker (1) has selected the standard heat of formation as -190.2 kcal/mol which is adopted in the tabulation. The heat of formation was derived from two independent paths. The first path involves $\Delta H_f^\circ(\text{Ca}^{++}, \infty \text{H}_2\text{O}) = -129.74$ kcal/mol (1), $\Delta H_f^\circ(\text{Cl}^-, \infty \text{H}_2\text{O}) = -39.952$ kcal/mol (2) and the heat of solution of $\text{CaCl}_2(\text{c})$ in water (3, 4, 5, 6, 7). The second path involves the heats of reaction of $\text{Ca}(\text{c})$, $\text{CaO}(\text{c})$ and $\text{CaCl}_2(\text{c})$ in aqueous HCl solution (1, 5-20).

Heat Capacity and Entropy

Kelley and Moore (21) measured the low temperature heat capacities in the temperature range from 52.6° to 295.1°K and made an extrapolation to 0°K which yielded an entropy of 4.59 ± 0.4 eu at 50.12°K. We have adopted the measured heat capacities, but made our own extrapolation to 0°K by comparison with the measured heat capacities of $\text{BaCl}_2(\text{c})$ (22) and $\text{SrCl}_2(\text{c})$ (23) from 6° to 50°K. The extrapolation gives $S_{50}^\circ = 2.45 \pm 1$ eu, which is used in the table. Moore (24) measured high temperature enthalpy data from 403.7° to 1687°K by drop calorimetry. The low temperature heat capacities and high temperature enthalpy data are smoothly joined at 298°K. The deviations of the observed enthalpies from the adopted values are about 21 near 400-500°K and only a few tenths percent at higher temperatures. Dworkin and Bredig (25) determined drop-calorimetrically $H_{1045}^\circ - H_{298}^\circ = 14.3$ kcal/mol, which is in very good agreement with the adopted value of 14.2 kcal/mol.

Melting Data

The adopted melting point 1045°K was determined by T. V. Tokareva (26). Dworkin and Bredig determined the heat of fusion $\Delta H_{1045}^\circ = 6.78 \pm 0.1$ kcal/mol by drop calorimetry. Chiotti, Gartner, Stevens and Saito (27) also measured the heat of fusion $\Delta H_{1055}^\circ = 6.79 \pm 0.2$ kcal/mol in an adiabatic calorimeter. The adopted heat of fusion, 6.822 kcal/mol, is calculated from the difference between the observed relative enthalpy of the liquid and the adopted value for the crystal at the melting point.

Sublimation Data

The heat of sublimation is calculated from the heats of formation of $\text{CaCl}_2(\text{c})$ and $\text{CaCl}_2(\text{g})$.

$$\Delta H_v^{\circ} = 56.2 \text{ kcal/mol}$$

Heat of Formation

The heat of formation is calculated from that of the crystal by adding the heat of melting and the difference between H_{1045}° and H_{298}° for the crystal and the liquid.

Heat Capacity and Entropy

The constant heat capacity above the assumed glass transition at 700°K is derived from high temperature enthalpy data in a drop calorimeter from the melting point up to 1667°K by G. E. Moore, J. Amer. Chem. Soc. **65**, 1700 (1943). Below the glass transition point, the heat capacity is assumed to be the same as that of the crystal. A. S. Dworin and M. A. Bredig, J. Phys. Chem. **67**, 697 (1963), reported $C_p(\ell) = 23.6$ gibbs/mol from enthalpy measurements in a short temperature range by drop calorimetry.

The entropy $S_{298.15}^{\circ} = 29.608$ gibbs/mol is calculated in a manner analogous to that of the heat of formation.

Melting Data

See the crystal table for details.

Vaporization Data

The boiling point is calculated as the temperature at which $\Delta G = 0$ for $\text{CaCl}_2(\ell) + \text{CaCl}_2(g)$. The heat of vaporization is the difference in ΔH_m° between liquid and gas.

Heat Capacity and Entropy

The linear structure and vibrational frequencies were determined by D. White and co-workers (g) in the matrix-infrared-spectrometric studies. The linear structure is consistent within experimental error with the electric-quadrupole-deflection studies (2), and electron-diffraction data (g). Hayes (g) has qualitatively rationalized the linear structure through molecular orbital theory.

The bond length was measured by Akishin and Spiridonov (g). The moment of inertia is 74.174 × 10⁻³⁹ g cm².

Heat of Formation

Hastie and Margrave (1) have recently reviewed the dissociation energy of CaF and conclude that it is 127.5 ± 2.5 kcal/mol. The analysis below considers basically the same data except that all values are JANAF.

Hildenbrand and Murad (2) in a mass spectrometric determination of the equilibria among BF, BF₂, Ca, CaF and CaF₂ reported equilibrium constants for the reaction

(A) $\text{Ca(g)} + \text{CaF}_2\text{(g)} \rightarrow 2\text{CaF(g)}$.

Blue et al. (3) have also examined several equilibria mass-spectrometrically and report equilibrium constants for reaction

(B) $\text{Ca(g)} + \text{CaF}_2\text{(c)} \rightarrow 2\text{CaF(g)}$ and reaction

(C) $\text{Ca(g)} + \text{AlF}_3\text{(g)} \rightarrow \text{Al(g)} + \text{CaF(g)}$.

Ryabova and Gurvich (4) give a heat of dissociation from flame studies for the reaction

(D) $\text{CaF(g)} \rightarrow \text{Ca(g)} + \text{F(g)}$.

The remaining reactions considered by Hastie and Margrave (1) were not included since they involved subtracting reactions not performed simultaneously, or involve species such as SiF₂ whose heat of formation is dependent on that of CaF and CaF₂.

Reference	Range °K	Reaction	Points	ΔH_f° kcal/mol	Drift	ΔH_f° kcal/mol
Hildenbrand (2)	1583 - 1734	A	15	11.5 ± 6.8	14.70 ± 1.27	2.2 ± 4.1

					32.97	-65.6 ± 3.2

* 1 point rejected due to failure of a statistical test

** Calculated from third law value when available

The auxiliary heats of formation used were, in kcal/mol, AlF, g = -63.4, Al, g = 78, CaF₂, g = -187.5, CaF₂, c = -293.0 and Ca, g = 42.85.

We adopt a median value of $\Delta H_f^{\circ}(298.15)(\text{CaF, g}) = -65 \pm 2$ kcal/mol which corresponds to a heat of dissociation of 126.7 ± 2 kcal/mol.

Heat Capacity and Entropy

Herzberg (6) gives the vibrational constants and electronic levels, Harvey (7) has reported a value for B_0 which corresponds to a bond length of 2.02 Å. The Morse potential function was used to calculate a_e .

 $\Delta H_f^\circ = 1.14 \pm 0.1$ kcal/mol
 $\Delta H_m^\circ = 7.10 \pm 0.1$ kcal/mol
 $\Delta H_{298.15}^\circ = 105.5 \pm 0.8$ kcal/mol

CaF₂S_{298.15} = 16.39 ± 0.08 gibbs/mol

Tt = 1424 ± 20°K (α-β)

Tm = 1691 ± 5°K

Heat of Formation

Torgeson and Sahama (1) measured the heat of solution of CaO in aqueous 20.1% HF as -54.96 ± 0.02 kcal/mol. Using ΔH_f° (CaO, c) = -151.79 kcal/mol (2), ΔH_{298}° (H₂O, l) = -68.317 kcal/mol (3) and ΔH_{298}° (HF, 4.4% H₂O) = -76.60 kcal/mol (4), we obtain ΔH_f° (CaF₂, c) = -293.6 ± 0.6 kcal/mol.

Smyslyayev and Edeleva (5) report the solubility product of CaF₂ as $2.7 \pm 0.27 \times 10^{-11}$ in dilute HCl, which yields ΔG_{298}° = 14.42 kcal/mol for the reaction CaF₂(c) + Ca²⁺(∞, aq.) + 2F⁻(∞, aq.). Using ΔG_f° (Ca²⁺, ∞ aq.) = -132.30 kcal/mol (2) and ΔG_f° (F⁻, ∞ aq.) = -66.95 kcal/mol (4) we obtain ΔG_f° (CaF₂, c) = -280.84 ± 0.6 kcal/mol, which using the adopted functions yields ΔH_f° (CaF₂, c) = -293.1 ± 0.6 kcal/mol.

Vecher and Vecher (11) have measured the ent of a high temperature solid state cell and report ΔG_{1700}° = -17.6 ± 0.2 kcal/mol for the reaction CaO(c) + HgF₂(c) + CaF₂(c) + MgO(c). This reduces to ΔH_{298}° = -17.6 kcal/mol which, using JANAF values for HgO and HgF₂ and CaO from reference 2, yields ΔH_{298}° (CaF₂, c) = -294.4 ± 1.3 kcal/mol.

Kohlrausch (13) reported the solubility of CaF₂ and fluorapatite, which yield solubility products of 3.6×10^{-11} and 2.8×10^{-11} . From these we obtain, as above, ΔH_{298}° (CaF₂, c) = -292.9 and -293.1 kcal/mol.

Guntz (13) made measurements on the neutralization of Ca(OH)₂(aq) and HF(aq) which yield ΔH_f° (CaF₂, c) = -293.1 kcal/mol, according to Parker (2).

A median value of ΔH_{298}° (CaF₂, c) = -293 ± 1.5 kcal/mol is adopted.

Heat Capacity and Entropy

Huffman and Norwood (6) have measured the low temperature heat capacity in the range 3.6° to 30°K. Eucken and Schwes (7) in the range 17° to 85°K and Todd (8) from 54° to 296.5°K. We have fitted a smooth polynomial curve through the data of references 6 and 8 and the yields S_{298}° = 16.39 ± 0.08 eu based on S_{298}° = 0.0002 eu. The values of reference 7 deviate considerably at the lowest temperatures but are in reasonable agreement at higher temperatures.

The high temperature enthalpy of calcium fluoride has been reported by Naylor (9) to 1789°K, Krestnikov and Karetnikov (10) to 1273°K, and Lyashenko (11) to 1490°K. All the data are in approximate agreement and the more extensive results of Naylor on a very pure sample are adopted. The heat capacities, below 1424°K were derived from a polynomial fit of the enthalpy data of the form $H = at^3 + bt^2 + ct + d/T + e/T^2$.

Transition Data

The temperature of transition is that reported by Naylor (9), the large uncertainty has been assigned since at 1424°K the enthalpies indicate complete conversion to β-CaF₂, and the next lower point is at 1407°K. Evidence in support of a transition in this region comes from Lyashenko (11) whose plot indicates a break between 1273° and 1413°K. In addition, SrCl₂ which has the fluorite structure has a transition near the melting point. The enthalpy of transition is that reported by Naylor (9).

Melting Data

McCreary (12) reports the melting point of a 99.1% pure sample as 1687 ± 5°K. Porter and Brown (13) report 1675 ± 5°K as the melting point of 99.81 pure CaF₂ and Rogers et al. (14) obtained 1694°K as the melting point. The adopted melting point 1691 ± 5°K, for a sample of natural fluorite of high purity, was reported by Naylor (9). The heat of melting, 7100 cal, is that measured by Naylor (9). Three determinations from high temperature phase diagrams give 7750 ± 350 cal (15), 5500 cal (16) and 9800 cal (14).

Sublimation Data

See the CaF₂(g) table for details.

CALCIUM DIFLUORIDE (CaF₂)

GFW = 78.0768

 $S_{298}^{\circ} = 22.125$ gibbs/mol $\Delta H_{298}^{\circ} = -283.477 \pm 1.5$ kcal/mol $\Delta H_m^{\circ} = 7.10 \pm 0.1$ kcal/mol $T_m = 1691 \pm 5^{\circ}\text{K}$ $\Delta H_v^{\circ} = 73.78 \pm 0.8$ kcal/mol $T_b = 2806.5 \pm 30^{\circ}\text{K}$

Heat of Formation

The heat of formation is obtained from that of the crystal by adding the heat of melting and the difference between $H_{1691} - H_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is derived from the heat content measurements of B. F. Naylor, J. Am. Chem. Soc. **57**, 150 (1943). The heat capacity is constant in the real liquid range but at 1000°K a glass transition is assumed below which it follows that of the crystal. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See the crystal table for details.

Vaporization Data

The boiling point is calculated as the temperature at which $\Delta G = 0$ for the vaporization process. The heat of vaporization is the difference in $\Delta H_{T_b}^{\circ}$ between liquid and gas.

Calcium Difluoride (CaF₂)

GFW = 78.0768

CALCIUM DIFLUORIDE (CaF₂) (IDEAL GAS)

Point Group = C_{2v}

$\Delta H_f^\circ = -187 \pm 2$ kcal/mol

$\Delta H_f^\circ = -187 \pm 2$ kcal/mol

$\Delta H_{298.15}^\circ = -187.5 \pm 2$ kcal/mol

Ground State Quantum Weight = 1

$S_{298.15}^\circ = 65.41 \pm 0.5$ gibbs/mol

Bond Distance: Ca-F = 2.1 Å

Bond Angle: F-Ca-F = 135 ± 7°

Product of the Moments of Inertia: $I_{AB}I_C = 1.2836 \times 10^{-114}$ g³ cm⁶

$\sigma = 2$

Calcium Difluoride (CaF₂)

(Ideal Gas) $\Delta G^\circ = 78.0768$

Dec. 31, 1968

The heat of formation is obtained from that of the crystal by adding $\Delta H_{298.15}^\circ$. The vapor pressure data of five authors was analysed by 2nd and 3rd law methods to give $\Delta H_{298.15}^\circ$ as listed below. Note that the drifts are small and both positive and negative confirming the correctness of the functions used.

Reference	Range °K	Points	2nd law	3rd law	Drift
Freeman (1)	1463 - 1668	9	106.2 ± 3.7	105.66 ± 0.9	-0.2 ± 2.3
Blue et al. (2)	1246 - 1498	6	99.6 ± 2.5	106.00 ± 1.0	4.1 ± 2.0
Schulz and Searcy (3)	1421 - 1683	34	102.4 ± 0.3	104.00 ± 0.2	1.0 ± 0.2
Pottier (4)	1823	1		106.4	
Ruff and LeBoucher (5)	2086 - 2208	7	106.7 ± 4.8	105.22 ± 0.5	-0.7 ± 2.2
Blue et al. (2) *	1242 - 1669	19	104.7 ± 0.5		

* This set was not analysed by the third law since the absolute pressures were adjusted by the authors to match their weight loss values.

A median value of 105.5 ± 0.5 kcal/mol is adopted for the heat of sublimation which yields $\Delta H_{298.15}^\circ$ (CaF₂, g) = -187.5 ± 2 kcal/mol.

Heat Capacity and Entropy

The bond length was measured by Akishin and Spiridonov (6), but the diffraction patterns were interpreted as indicating a linear molecule. The vibrational frequencies and bond angle are those reported by Calder (7) using matrix isolation spectroscopy and isotopically enriched materials.

The individual moments are $I_A = 2.092 \times 10^{-39}$, $I_B = 2.3749 \times 10^{-38}$, and $I_C = 2.5840 \times 10^{-38}$ g cm².

Bond Distance: Ca-O = [1.82] Å	
Bond Angle: Ca-O-H = [180°]	
Rotational Constant: B ₀ = [0.3926] cm ⁻¹	
$\sigma = 1$	

Heat of Formation

Cotton and Jenkins (1) determined the equilibrium constants in the temperature range 1570°K-2030°K for the reaction $\text{Ca}(g) + \text{H}_2\text{O}(g) \rightarrow \text{CaOH}(g) + \text{H}(g)$ by atomic absorption spectroscopy in a fuel-rich hydrogen-nitrogen-oxygen flame. Using all JANAF functions, third law analyses of the data give $\Delta H_f^\circ_{298} = 13.8 \text{ kcal/mol}$ and the drift $1.9 \pm 2.9 \text{ eu}$. This leads to the heat of formation, $\Delta H_f^\circ(\text{CaOH}, g) = -53.3 \text{ kcal/mol}$ which is adopted in the tabulation. The bond dissociation energy, $D_0(\text{Ca-OH})$, is 104.6 kcal/mol .

Rybava and Gurvich (2) reported the bond dissociation energy $D_0(\text{Ca-OH})$ as 100 kcal/mol . Schofield and Sugden (3) found $D_0(\text{Ca-OH})_2$ as $217 \pm 12 \text{ kcal/mol}$. Using the relation $D_0(\text{H-X})/D_0(\text{H-M-X}) = 0.47$ suggested by Kent, McDonald and Margrave (4), we obtain $D_0(\text{Ca-OH}) = 102 \text{ kcal/mol}$.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that gaseous NaOH, KOH, CaOH and RbOH are linear (5, 6, 7). This evidence also confirms the prediction of A. D. Walsh (8) that "HAB" molecules with 10 or less valence electrons (CaOH has 9 valence electrons) will be linear in their ground state.

The ground state is assumed to be Σ by analogy with isoelectronic CaF (9). The electronic levels are estimated from band spectra of CaOH reported by Gaydon (10).

The bond distances O-H and Ca-O are assumed to be the same as those in $\text{H}_2\text{O}(g)$ and $\text{CaO}(g)$, respectively (10, 11).

The moment of inertia is $7.1295 \times 10^{-39} \text{ g cm}^2$.

The O-H stretching frequency, 3600 cm^{-1} , is estimated from those of $\text{H}_2\text{O}(g)$ (10) and $\text{CaOH}(g)$ (12). The bending frequency, 320 cm^{-1} , is estimated by comparison with those of NaOH, CaOH and RbOH (5, 7). The Ca-O stretching frequency, 733 cm^{-1} , is estimated to be the same as that of $\text{CaO}(g)$ observed by Hultin and Lagerqvist (11) and Brewer and Hauge (13).

		93366.6	5	
		93998.7	3	
		94332.8	1	

Heat of Formation.

The heat of formation was calculated from the equation: Cl(g) - e⁻ → Cl⁺(g) with the JANAP auxiliary value for Cl(g) using an I.P. = 1.04991 X 10⁵ cm.⁻¹ (300.206 kcal/mole) obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, loc. cit. The electronic levels above 1 X 10⁵ cm.⁻¹ were omitted because their contribution is negligible below 6000°K. The H^o-H₂₉₈^o value at 0°K. is -1.526 kcal./mole.

CHLORINE UNINEGATIVE ION (Cl⁻)
(IDEAL GAS)
MOL. WT. = 35.45355
Ground State Configuration 1s₀
S°_{298.15} = 36.628 cal. deg.⁻¹ mole⁻¹
ΔH°_f 0 = -54.8 ± .5 kcal. mole⁻¹
ΔH°_f 298.15 = -55.9 ± .5 kcal. mole⁻¹

Electronic Levels and Quantum Weight

E, cm. ⁻¹	g _i
0.0	1
93143.8	5
93750.639	3
94553.707	1
95399.870	3

Heat of Formation.

The heat of formation was calculated from the equation: Cl(g) + e⁻ → Cl⁻(g) with the JANAF auxiliary values for Cl(g); using the measured electron affinity = 3.613 e.v. (83.316 kcal/mole) obtained from R. S. Berry and C. W. Reimann, J. Chem. Phys. **39**, 1540 (1963). Other calculated values for the electron affinity are: 3.70 e.v. reported by B. Edlen, J. Chem. Phys. **33**, 98 (1960) and 3.56 e.v. reported by E. Clementi, A. D. McLean, D. L. Reimondi and M. Yoshimine, Phys. Rev. **133**, A1274 (1964).

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Argon. The electronic levels above 1 X 10⁵ cm.⁻¹ were omitted because their contribution is negligible below 6000°K. The H°-H°₂₉₈ value at 0°K. is -1.481 kcal/mole.

CESIUM CHLORIDE (CsCl)

(CRYSTAL)

GFW = 168.358

S_{298.15}° = 24.183 ± 0.005 gibbs/mol $\Delta H_f^{\circ} = -105.88 \pm 0.2$ kcal/mol

Tf(α-β) = 743°K

 $\Delta H_f^{\circ} = -105.84 \pm 0.2$ kcal/mol

Tm = 918°K

 $\Delta H_m^{\circ} = 3.8$ kcal/mol $\Delta H_{298.15}^{\circ}(\text{to monomer}) = 48.74$ kcal/mol

Heat of Formation

The heat of solution (ΔHsoln) of CsCl(c) in water has been measured by Forcand (1, 2), Haigh (3), Samoilov (4, 5), and Rodnikova (6). Based on their results, Parker (7) derived the corresponding ΔHsoln_{298.15}(∞ H₂O) values as 4.30, 4.32, 4.08, 4.25, 4.18 and 4.18 kcal/mol. Borob'ev (8) determined the same quantity and reported ΔHsoln₂₉₈(CsCl, ∞ H₂O) = 4.20 ± 0.04 kcal/mol. Using this value, 4.20 kcal/mol, and ΔH_f[°]₂₉₈ = -61.69 (9) and -39.952 kcal/mol (10) for Cs⁺(∞ H₂O) and Cl⁻(∞ H₂O), respectively, we evaluate ΔH_f[°]₂₉₈(CsCl, c) = -105.84 ± 0.2 kcal/mol, which is adopted.

Heat Capacity and Entropy

Taylor (11) measured the low temperature heat capacities, 7.19 - 299.38°K, with an adiabatic calorimeter; the sample purity was >99.95 per cent. Employing these data we derive the value $\Delta_{298}^{\circ} = 24.183$ eu based on $S_{298.15}^{\circ} = 0.031$ eu.

The high temperature enthalpies, 385.2 - 904.9°K, were measured by Kaylor (21, 22, 23), using a Bunsen ice calorimeter and a CsCl sample of 99.8 per cent purity. The heat capacities derived from the reported enthalpy data at temperatures 385.2 - 740.5°K appear too low (less than the adopted Cp's systematically) by 0.9 gibbs/mol to join smoothly with the low temperature data at 298°K. The Cp values derived from the measured enthalpy data in the temperature range 760 - 920°K increase rapidly from 14.46 to 16.3 gibbs/mol. In order to rationalize this situation, we adopt the high temperature heat capacities, 298 - 743°K, for CsCl(α) obtained by linear extrapolation of the low temperature data. The Cp values for CsCl(β) are adjusted such that the rate of increase in heat capacities is linear and less rapid than the original one, and the total enthalpy remains essentially unchanged. The discrepancy between the high and low temperature Cp for CsCl(α) may be caused by the incomplete β → α phase conversion involved. In order to resolve this discrepancy, independent enthalpy measurements using a high purity sample with composition well characterized before and after each drop experiment seem necessary.

Transition Data

The temperature of transition (in °K) has been reported by many investigators as 718 (14), 752 (15), 745 (16), 742 (21), 742.5 (12), 743 (20), and 733 (17), using different methods and samples of different purity. The value adopted is 743°K.

The heat of transition (in kcal/mol) was reported to be 1.8 (14), 1.55 (18), 1.4 (19), 0.80 (21), 0.58 (12), 0.90 (13), and 1.1 (17). A median value 0.90 kcal/mol is tentatively adopted.

Melting Data

See CsCl(β) table for details.

Heat of Sublimation

ΔH_{298}° is calculated as the difference between ΔH_f[°] for CsCl(g) and CsCl(c).

GFW = 168.358

$$S_{298.15}^{\circ} = 24.309 \text{ gibbs/mol}$$

$$\Delta H_f^{\circ} = -103.84 \pm 2.0 \text{ kcal/mol}$$

$$T_m = 918^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = 3.8 \pm 1 \text{ kcal/mol}$$

$$T_b = 1597.3^{\circ}\text{K}$$

$$\Delta H_v^{\circ} = 27.52 \text{ kcal/mol of liquid (to equilibrium mixture)}$$

Heat of Formation

 $\Delta H_f^{\circ}(s) \text{ is obtained from } \Delta H_f^{\circ}(c) \text{ by adding } \Delta H_m^{\circ} \text{ and the difference between } H_{918}^{\circ} - H_{298}^{\circ} \text{ for crystal and liquid.}$

Heat Capacity and Entropy

The enthalpies of CsCl(*l*) at temperatures 923.6 - 1164.0°K were measured with a Bunsen ice calorimeter by Kaylor (1, 2). Dworkin (3) derived the heat capacity of CsCl(*l*) as 18.5 gibbs/mol from enthalpy data at temperatures 918 - 980°K. This value is adopted since it is in agreement with the enthalpy values reported by Kaylor et al. The heat capacity at temperatures above 1168 and below 923.6°K is assumed to be 18.5 gibbs/mol. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting temperature (in °K) of CsCl(*c*) has been determined by many investigators as 904 ± 3 (4), 918 (5), 912 (6), 911 (7), 918 (8), 916 (9), and 919 (13). The cause of the discrepancies is probably due to the difference in purity of the samples. The melting temperature adopted is 918°K.

The heat of melting (in kcal/mol) was reported to be 4.84 (10), 4.97 (15), 4.58 (10), 4.96 (11), and 4.78 (2), which were obtained calorimetrically. Using a modification of Kelley's method of obtaining heat of melting from freezing point data on binary systems involving CsCl (18), we derive the value of ΔH_m° as 3.6 - 4.0 kcal/mol, based on the following systems:

CsCl-NaCl (5), CsCl-CuCl (9), CsCl-AgCl (9), CsCl-LiCl (9), and CsCl-Cs₃(PO₃)₃ (12). The heat of melting for CsCl(*c*) is tentatively adopted as 3.8 kcal/mol. The ΔH_m° values obtained calorimetrically are not used due to the uncertainties of the state of the sample before and after the enthalpy measurements.

Vaporization Data

T_b is the temperature at which the calculated total pressures of CsCl(*g*) and Cs₂Cl₂(*g*) equal one atmosphere. The vapor composition at *T_b* is derived as CsCl 80.4 per cent and Cs₂Cl₂ 19.6 per cent. The boiling point of CsCl(*l*) has been determined by several investigators as 1562 (12), 1572 (18), and 1576 (19). The heat required to vaporize one mole of liquid to the above vapor mixture at *T_b* is ΔH_v° .

Heat of Formation

The total pressures of CsCl(g) and $\text{Cs}_2\text{Cl}_2(\text{g})$ over CsCl(c) and CsCl(l) in the temperature range 605 - 1577°K have been determined by manometric, transpiration and Knudsen effusion methods by many investigators. Based on the reported results, the partial pressures of CsCl(g) and $\text{Cs}_2\text{Cl}_2(\text{g})$ are calculated using the derived free energy functions for CsCl(c), CsCl(l), CsCl(g) and $\text{Cs}_2\text{Cl}_2(\text{g})$, and the heats of sublimation and vaporization which are adjusted so that the sum of the calculated partial pressures of CsCl(g) and $\text{Cs}_2\text{Cl}_2(\text{g})$ approaches the measured total pressures, and the evaluated second and third law ΔH_f^{298} values are in reasonable agreement. The results obtained are presented in the table below. The value of $\Delta H_f^{298}(\text{CsCl}, \text{g})$ adopted is $-57.4 \pm 1 \text{ kcal/mol}$.

Gaydon (10) reported $D_0(\text{Cs-Cl}) = 4.6 \pm 0.2 \text{ eV}$ or $106.08 \pm 4.61 \text{ kcal/mol}$. Using this D_0 value and $\Delta H_f^\circ = 18.683$ and 28.52 kcal/mol for Cs(g) and Cl(g), we evaluate $\Delta H_f^{298} = -59.4 \pm 4.6 \text{ kcal/mol}$ for CsCl(g), which is in fair agreement with the adopted value.

Heat Capacity and Entropy

Clausen (11) studied the pure rotational spectra of CsCl(g) in the 0.36 - 3 mm range of the microwave region with the molecular-beam spectrometer, and derived the values of B_e , α_e , ω_e , $\omega_e x_e$ and r_e , which are adopted and corrected to the average isotopic species.

The Cs-Cl bond distance was measured as $3.06 \pm 0.03 \text{ \AA}$ by the electron diffraction method by Maxwell (12), which is not used. Similar values of B_e and α_e were reported by Honig (13) and Rice (14), determined from microwave and infrared spectra, respectively. Barrow (15) gave $\omega_e = 240 \text{ cm}^{-1}$ (CsCl₃₅) which is significantly different from the adopted value 214.22 cm^{-1} for CsCl₃₅ and the value $209 \pm 6 \text{ cm}^{-1}$ reported by Rice (14). The moment of inertia is $3.924 \times 10^{-38} \text{ g cm}^2$.

 $\Delta H_g^0 298.15 = 37.2 \pm 0.2$ kcal. mole⁻¹ of trimer

Heat of Formation.

There have been three calorimetric determinations of the heat of formation. Thomsen, "Thermochemische Untersuchungen", Barth, Leipzig (1882-1886) reported -32.675 kcal. mole⁻¹. Barthelot, Ann. Chim. Phys. 20, 504 (1880) reported -35.6 kcal. mole⁻¹ and H. V. Wartenberg and H. Werth, Z. physik. Chem. A 151, 109 (1930) reported -32.1 ± 0.4 kcal. mole⁻¹. In addition, values of the heat of formation have been derived from several sets of equilibrium data. A. A. Noyes and M. Chow, J. Am. Chem. Soc. 40, 739 (1918) from a study of cell potentials derived $\Delta H_f^0 = 7.19$ kcal. for the reaction $\text{Cu(c)} + \text{HCl(aq)} \rightarrow \text{CuCl(c)} + 1/2 \text{H}_2(\text{g})$ which yields $\Delta H_f^0 298(\text{CuCl}) = -32.76$ kcal. mole⁻¹. Several investigators have studied the reaction $2\text{CuCl(c)} + \text{H}_2(\text{g}) \rightarrow 2\text{Cu(c)} + 2\text{HCl(g)}$ and its reverse reaction. These include A. B. Eggesarian, Trans. Am. Electrochem. Soc. 51, 449 (1927) who reported equilibrium constants which result in 2nd and 3rd law heats of reaction of 24.3 and 23.2 kcal. mole⁻¹; A. F. Kapustinsky, J. Am. Chem. Soc. 59, 460 (1936) who obtained similarly 20.1 and 21.8 kcal. mole⁻¹; S. A. Shchukarev and M. A. Orenskaia, Z. Obshchei. Khim. 24, 1928 (1954) obtained 25.4 and 21.5 kcal. mole⁻¹ for the 2nd and 3rd law heat of reaction. These yield values for $\Delta H_f^0 298(\text{CuCl})$ ranging from -32.1 to -34.8 . M. Watanabe, Bull. Inst. Phys. Chem. Res. 9, 94 (1929) from cell studies reports $\Delta H_f^0 298(\text{CuCl}) = -34.6$ kcal. mole⁻¹. A value of $\Delta H_f^0 298$ can also be obtained from $\Delta H_f^0(\text{CuCl}_2(\text{g}))$, which is fixed independently and known with good precision. Using the 3rd law heat of sublimation of CuCl(c) to trimer determined by D. W. Magee, Doctoral Thesis, Ohio State University (1955) [See trimer table], we obtain $\Delta H_f^0 298 \text{ CuCl(c)} = -33.01 \pm 0.3$ kcal. mole⁻¹. A weighted average of -33.0 ± 0.4 kcal. mole⁻¹ was adopted.

Heat Capacity and Entropy.

The entropy of CuCl was obtained from the several pieces of equilibrium data reported above and the adopted $\Delta H_f^0 298$. A weighted average of 20.8 ± 1 cal/(mole-deg) was adopted for $S_{298}^0 \text{ CuCl(c)}$. The enthalpy and heat capacity above $298^\circ\text{K}.$ have been reported by A. N. Kretzovnikov and O. A. Kretzovnikov, Jour. Oen. Chem. (USSR) 5, 955 (1936). However these values were not adopted since they do not give reasonable heat capacities and other data by these workers is not in agreement with established values. Heat capacities equal to those of AgCl , as given by K. K. Kelley, U. S. Bureau of Mines Bulletin 584, Washington 1960, were adopted here above $298^\circ\text{K}.$

Melting Data.

The temperature end heat of melting were those selected by K. K. Kelley, U. S. Bur. Mines Bulletin 393 (1936), from phase studies. The heat of melting was reported by Kretzovnikov and Kretzovnikov loc. cit. as 2.54 kcal. mole⁻¹.

Sublimation Data.

The heat of sublimation was calculated from the adopted heats of formation at 298° for the reaction $x \text{ CuCl(c)} \rightarrow (\text{CuCl})_x(\text{g})$ where $x = 1$ or 3 . See the respective gas tables for details.

Heat of Formation.

Calculated from ΔH_f° 298 of the crystal plus ΔH_m° and the difference between H_m - H_{298} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated to be constant at 8 cal. deg⁻¹ gm. atom⁻¹. The entropy was calculated in a manner analogous to that of the heat of formation.

Boiling Data.

The boiling point and heat of vaporization were calculated from the respective liquid, monomer and trimer gas tables. The boiling point was taken as the point where the total pressure reached 1 atm. At this point the partial pressures are 0.021 atm. of monomer and 0.979 atm. of trimer.

COPPER MONOCHLORIDE (CuCl)

(IDEAL GAS)

MOL. WT. = 98.993

Ground State Configuration $1\sum^+$
 $S_{298.15}^0 = 56.667$ cal. deg.⁻¹ mole⁻¹
 $\Delta H_f^0 = 21.80 \pm 0.4$ kcal. mole⁻¹
 $\Delta H_f^0_{298.15} = 21.77 \pm 0.4$ kcal. mole⁻¹

Electronic Levels and Multiplicities

$$\frac{\epsilon_i, \text{ cm.}^{-1}}{0} \frac{g_i}{1}$$

$\omega_e = 414.9$ cm.⁻¹
 $\alpha_e = 0.1761$ cm.⁻¹
 $\omega_e x_e = 1.577$ cm.⁻¹
 $\alpha_e = 0.0001$ cm.⁻¹
 $r_e = 2.050$ Å
 $\sigma = 1$

Heat of Formation.

The heat of formation was obtained from the equilibrium data of L. Brewer and N. L. Lofgren, J. Am. Chem. Soc. 72, 3038 (1950). They studied the reaction $\text{Cu}(c) + x \text{HCl}(g) \rightarrow \text{CuCl}_x(g) + x/2 \text{H}_2(g)$ by measuring the amount of CuCl formed when various ratios of HCl:H₂ were passed over heated copper. Brewer and Lofgren analyzed the data by a least squares fitting technique and deduced partial pressures of monomer and trimer. The monomer pressure were subjected to second and third law analysis and gave $\Delta H_f^0_{298} = 46.85 \pm 3.2$ and 43.83 ± 0.4 kcal. mole⁻¹ respectively. The 3rd law value yields $\Delta H_f^0_{298} \text{ CuCl}(g) = 21.77 \pm 0.4$ kcal. mole⁻¹, which was adopted.

Heat Capacity and Entropy.

The molecular constants were corrected for normal isotopic abundance of both copper and chlorine and were calculated from the values for $^{63}\text{Cu}^{35}\text{Cl}$ given by R. K. Aeundi, P. R. Reo and J. K. Brody, Nature 192, 444 (1961). The rotational constants were in good agreement with those reported by A. Lagerqvist and V. Leszerov-Giremov for $\text{Cu}^{63}\text{Cl}^{35}$, Naturwissenschaften 49, 68 (1961).

ClCu

Chlorine Monofluoride (ClF)

(Ideal Gas) Mol. Wt. = 54.4514

ClF

MOL. WT. = 54.4514

CHLORINE MONOFLUORIDE (ClF)

(IDEAL GAS)

Ground State Configuration $1\Sigma^+$ $\Delta H_f^\circ 0 = -12.12 \pm 0.6 \text{ kcal. mole}^{-1}$
 $S_{298.15}^\circ = 52.064 \pm 0.01 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^\circ 298.15 = -12.14 \pm 0.6 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

State	ξ , cm. ⁻¹	g _i
$1\Sigma^+$	0	1
$3\Sigma^+$	19,592	1
$3\Pi_0$	19,592	2
$3\Pi_2$	19,592	2

$\omega_e = 784.39 \text{ cm.}^{-1}$ $\sigma^- = 1$
 $\omega_e = 6.20 \text{ cm.}^{-1}$ $r_e = 1.62913 \text{ \AA}$
 $\omega_e = 0.004329 \text{ cm.}^{-1}$

Heat of Formation

The $\Delta H_f^\circ 298.15 = -12.14 \text{ kcal. mole}^{-1}$ was calculated from the dissociation energy ($D_0^\circ = 58.99$) obtained from the visible band spectra measured by H. Schmitz and H. J. Schumacher, Z. Naturforsch. 2a, 359 (1947) and A. L. Wahneftig, J. Chem. Phys. 10, 248 (1941). The convergence limit of $21,512 \pm 20 \text{ cm.}^{-1}$ for the A state leads to the selected D_0° assuming that the products are $\text{Cl}(^2P_{3/2})$ and $\text{F}(^2P_{3/2})$ or to $D_0^\circ = 60.36$ assuming $\text{Cl}(^2P_{3/2})$ and $\text{F}(^2P_{1/2})$. Calorimetric values bracket the two possibilities but more weight was given to the results of Wicke.

Method	Reaction	Observation
1 Spectroscopic	$\text{ClF} = \text{Cl}(^2P_{3/2}) + \text{F}(^2P_{3/2})$	$D_0^\circ = 58.99$
2 Spectroscopic	$\text{ClF} = \text{Cl}(^2P_{3/2}) + \text{F}(^2P_{1/2})$	$D_0^\circ = 60.36$
3 Calorimetric	$1/2 \text{ Cl}_2 + 1/2 \text{ F}_2 = \text{ClF}$	$\Delta H_{295}^\circ = -11.6 \pm 0.1$
4 Explosion method	$1/2 \text{ Cl}_2 + 1/2 \text{ F}_2 = \text{ClF}$	$\Delta H_0^\circ = -11.7 \pm 0.5$
5a Calorimetric	$\text{NaCl} + \text{ClF} = \text{NaF} + \text{Cl}_2$	$\Delta H_{290}^\circ = -24.5 \pm 0.5$
5b Calorimetric	$\text{NaCl} + 0.5 \text{ F}_2 = \text{NaF} + 0.5 \text{ Cl}_2$	$\Delta H_{290}^\circ = -39.5 \pm 0.5$

Heat Capacity and Entropy

The rotational constants were obtained from the microwave spectrum by D. A. Gilbert, A. Roberts and P. A. Ortolano, Phys. Rev. 76, 1723 (1949) and by D. A. Gilbert and A. Roberts Phys. Rev. 77, 742 (1950). The vibrational constants were obtained from the analysis vibration-rotation fine structure in the infrared by A. H. Nielsen and E. A. Jones, J. Chem. Phys. 19, 1117 (1951).

The rotational and vibrational constants were adjusted to $\text{Cl}^{35} = 75.4\%$ and $\text{Cl}^{37} = 24.6\%$.

DILITHIUM CHLORIDE FLUORIDE (Li₂ClF)

(Ideal Gas)

Mol. Wt. = 68.34

ΔH_f^o 298.15 = [-180.2] kcal. mole⁻¹

S_{298.15}^o = [64.037] cal. deg.⁻¹ mole⁻¹

ΔH_f^o 298.15 from National Bureau of Standards Report No. 6297, "Preliminary Report on the Thermodynamic Properties of Lithium, Beryllium, Magnesium, Aluminum, and their Compounds with Oxygen, Hydrogen, Fluorine, and Chlorine (Revised)", January, 1959. Cp from R. R. Koppang, C. M. Sherwood, and G. S. Bahn, Marquardt Corp., Van Nuys, Calif., "Some Provisional Tables of Species Thermodynamic Properties", October, 1959.

Magnesium Chloride Fluoride (MgClF)

(Ideal Gas) Mol. wt. = 78.7634

CIFMg

MAGNESIUM CHLORIDE FLUORIDE (MgClF) (IDEAL GAS) MOL. WT. = 78.7634

Dec. 31, 1960; Mar. 31, 1966

Point Group C_{2v}
 $\Delta H_f^o = [-135.6 \pm 5] \text{ kcal. mole}^{-1}$
 $\Delta H_f^o 298.15 = [-136.0 \pm 5] \text{ kcal. mole}^{-1}$

S^o 298.15 = [62.76] cal. deg.⁻¹ mole⁻¹
 Round State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

$\omega_e \text{ cm}^{-1}$
 [719](1)
 [205](1)
 [453](1)

Bond Distance: Mg-Cl = [2.18] Å Mg-F = [1.77] Å

Bond Angle: Cl-Mg-F = [170]°

Product of the Moments of Inertia: I_AI_BI_C = [1.5643 X 10⁻¹¹⁵] g.³ cm.⁶

σ = 2

Heat of Formation

The heat of formation is based on an estimated $\Delta H_f^o 298 = 0$ for the reaction $\text{MgCl}_2(\text{g}) + \text{MgF}_2(\text{g}) \rightarrow 2\text{MgClF}(\text{g})$, using $\Delta H_f^o 298.15 = -95.85$ and -176.2 kcal. mole⁻¹ for $\text{MgCl}_2(\text{g})$ and $\text{MgF}_2(\text{g})$, respectively.

Heat Capacity and Entropy

The bond angle is taken to be the value we have adopted for $\text{MgCl}_2(\text{g})$. The Mg-Cl and Mg-F bond distances are assumed to be the same as those in $\text{MgCl}_2(\text{g})$ and $\text{MgF}_2(\text{g})$. The vibration frequencies are the averages of those for $\text{MgCl}_2(\text{g})$ and $\text{MgF}_2(\text{g})$. The three principal moments of inertia are: I_A = 0.0977 X 10⁻³⁹, I_B = 39.958 X 10⁻³⁹ and I_C = 40.054 X 10⁻³⁹ g. cm.²

Heat of Formation.

The ΔH_f^o 298.15 of POCl₂ was estimated to be -228 kcal. mole⁻¹ from the ΔH_f^o 298.15 of PO₂ by assuming bond energies of 120 kcal. for D(P-F) and 80 kcal. for D(P-Cl). The D(P-F) and D(P-Cl) values were taken from E. Morawitz and L. T. D. Williams, J. Chem. Soc., 2485 (1955) Part I and E. Neale, L. T. D. Williams and V. T. Moores, J. Chem. Soc., 422 (1956) Part II.

Essentially the same ΔH_f^o 298.15 may be obtained by assuming a $\Delta H_f^o = 0$ for the following reaction:

$$\text{POCl}_3(\text{g}) + \text{POF}_3(\text{g}) \rightarrow \text{POCl}_2\text{F}(\text{g}) + \text{POF}_2\text{Cl}(\text{g})$$

Heat Capacity and Entropy.

The molecular constants were determined by L. O. Brockway and J. Y. Beach, J. Am. Chem. Soc., 50, 1836 (1938) and by Q. Williams, J. Sheridan, and W. Gordy, J. Chem. Phys., 20, 164 (1952). Brockway and Beach measured electron diffraction. Q. Williams et al. measured microwave spectra. Brockway and Beach assumed that the P-P-F and P-P-Cl angles were equal in PO₂Cl and POCl₂. An analysis of Brockway and Beach's data by Q. Williams et al., indicates that the angles in PO₂Cl, POCl₂, POClF, POCl₂F, POClF₂, and PO₂F should be 103° rather than the reported 106° ± 3°. The principal moments of inertia calculated from these parameters were I_A = 3.24319 X 10⁻³⁸ g.² cm.², I_B = 1.87015 X 10⁻³⁸ g.² cm.², and I_C = 3.13496 g.² cm.² X 10⁻³⁸.

The Raman spectra and vibrational frequencies for PO₂Cl were reported by M. L. Delvaux and P. Francois, Compt. Rend. 222, 550 (1946). The frequencies were reassigned by M. L. Delvaux and P. Francois in J. Chim. Phys. 46, 87 (1949).

Heat of Formation.

The ΔH°_f 298.15 = -37.97 kcal. mole⁻¹ was calculated from ΔH°_f 298 = 25.63 kcal. mole⁻¹ obtained by third law analysis of the equilibrium data of H. Schmitz and H. T. Schumacher, Z. Naturforsch. **28**, 362 (1947) for the reaction ClF₃(g) = ClF(g) + F₂(g). Similar values are obtained from the equilibrium data of K. Schifer and E. Wicke, Z. Elektrochemie **52**, 205-209 (1948). Calorimetric values scatter widely, as summarized below; these were given little weight.

Source	Method	Reaction	Observation ₂₉₈ (kcal. mole ⁻¹)	3rd Law Drift (e.u.)	ΔH° _f 298 (kcal. mole ⁻¹)
1e	K _p (523-623°K)	ClF ₃ (g) → ClF(g) + F ₂ (g)	ΔH° _f 298 = 25.63	0.8 ± 0.3	-37.97
2e	K _p (733°K)	ClF ₃ (g) → ClF(g) + F ₂ (g)	ΔH° _f 298 = 25.77	---	-37.91
2b	K _p (570-680°K)	ClF ₃ (g) → ClF(g) + F ₂ (g)	ΔH° _f 298 = 26.12	6 ± 3	-38.26

Heat Capacity and Entropy.

The structural constants were obtained from the microwave study of D. P. Smith, J. Chem. Phys. **21**, 609 (1953). The plunger distorted "m" structure is similar to that derived from X-ray studies of the solid by R. D. Burbank and P. N. Bennet, J. Chem. Phys. **21**, 802 (1953). Fundamental frequencies are taken from the infrared and Raman spectra of H. H. Claessen, B. Weinstein and J. G. Malm, J. Chem. Phys. **28**, 285 (1958). These data confirm the "m" structure as opposed to the pyramidal structure used in earlier spectral analyses.

Claessen, et al., loc. cit., calculate thermodynamic functions virtually identical with the JANAF values. These authors also correct the third law entropy reported by J. W. Gaiser, H. A. Bernhardt and G. D. Oliver, J. Am. Chem. Soc. **73**, 5725 (1951) from measurements of heat capacity (14-285°K.) and vapor pressure (226-303°K.). The entropy at the normal boiling point becomes S°_{284.91} = 67.04 cal. deg.⁻¹ mole⁻¹ when a non-ideality correction consistent with the dimer-monomer vapor equilibrium is applied. The corresponding statistical entropy, S°_{284.91} = 66.59 cal. deg.⁻¹ mole⁻¹, is consistent with the third law value within the probable error in the entropy of the liquid and the entropy of vaporization. The three principal moments of inertia are: I_A = 6.1114 X 10⁻³⁹, I_B = 1.81545 X 10⁻³⁸ and I_C = 2.42859 X 10⁻³⁸ g. cm.²

Chlorotrifluorosilane (ClSiF₃)
(Ideal Gas) Mol. Wt. = 120.547

Bond Distances: (Cl-P)_{basal} = 1.72 Å
(Cl-P)_{axial} = 1.82 Å
Bond Angles: P-I-P = 90°

Product of Moments of Inertia: I_AI_BI_C = 2.47289 x 10⁻¹¹³ g³ cm⁶
Cl-P = 4

Heat of Formation

The heat of formation was estimated by assuming that the ratio [A.B.E.(ClF₃)]/[A.B.E.(ClF₅)] - A.B.E.(ClF₅) was equal to [A.B.E.(BrF₃)]/[A.B.E.(BrF₅)] - A.B.E.(BrF₅), where A.B.E. represents average bond energy. All values were taken from these tables. A.B.E.(ClF₅) was thus calculated to be 36 kcal/mol which leads to ΔH^o = -57 ± 15 kcal/mol.

Heat Capacity and Entropy

O. M. Begun, W. H. Fletcher and D. P. Smith, J. Chem. Phys. 42, 2236 (1965), have reported the infrared spectra of the gas and the Raman spectra of the liquid. Their assignments have been adopted here, including one frequency 1/6 obtained from a valence force-field treatment. The values are consistent with those for IF₅(g) and BrF₅(g). D. P. Smith, Science 141, 1039 (1963), had previously reported three infrared bands. The structure of the molecule has not been determined but the spectra can only be interpreted assuming C_{4v} symmetry; this is in accord with IF₅ and BrF₅(g). Begun et al. assumed a square pyramidal structure with the chlorine in the base of the pyramid. There is some evidence that the chlorine may not lie in the basal plane but this would not appreciably affect the calculations. The structure adopted was that given by Begun et al. The individual moments of inertia are I_A = I_B = 25.7380 x 10⁻³⁹ g cm² and I_C = 37.3298 x 10⁻³⁹ g cm².

June 30, 1965

IRON MONOCHLORIDE (FeCl)

(IDEAL GAS)

MOL. WT. = 91.300

Ground State Configuration $6^5\Sigma$
 $S_{298.15}^{\circ} = [61.537] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^{\circ} 0 = 60 \pm 20 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{\circ} 298.15 = 60 \pm 20 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

ϵ_i , cm ⁻¹	$\frac{g_i}{6}$
0	[200]
[200]	[8]
[1000]	[8]
[4000]	[8]

 $\omega_e x_e = 1.19 \text{ cm.}^{-1}$ $\sigma = 1$ $\omega_e = 404.92 \text{ cm.}^{-1}$ $r_e = [2.09]$ $\omega_e = [0.00075] \text{ cm.}^{-1}$

Heat of Formation.

The dissociation energy (D_0°) of FeCl(g) was reported as $3 \pm 2 \text{ e.v.}$ ($69 \pm 46 \text{ kcal. mole}^{-1}$) by A. O. Ceydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. The corresponding $\Delta H_f^{\circ} 298.15$ (FeCl, g) was evaluated to be $56 \pm 46 \text{ kcal. mole}^{-1}$. By comparing $D(\text{Fe-O}) = 101 \text{ kcal. mole}^{-1}$ in FeO(g) with the coordinate bond energies obtained in organic complexes and iron carbonyl halides of $E(\text{Fe-O}) = 59.4$ and $E(\text{Fe-Cl}) = 37.3 \text{ kcal. mole}^{-1}$, reported by M. M. Jones, B. J. Yow and M. R. May, Inorg. Chem. 1, 166 (1962), the $D(\text{Fe-Cl})$ in FeCl(g) was estimated as $101 \times (37.3/59.4) = 63.3 \text{ kcal. mole}^{-1}$, yielding $\Delta H_f^{\circ} 298.15$ (FeCl, g) = $64 \text{ kcal. mole}^{-1}$. The adopted value of $\Delta H_f^{\circ} 298.15$ for FeCl(g) is $60 \pm 20 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The ground state configuration, ω_e and $\omega_e x_e$ (corrected to the average isotopic species) were obtained from O. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., New York, 1950. The Fe-Cl bond distance was assumed to be the same as that in FeCl₂(g). Hence the values of B_e and ω_e were calculated. The electronic levels and quantum weights were estimated by comparison with the electronic levels in Fe²⁺(g) reported by C. E. Moore, "Atomic Energy Levels", Circular of the National Bureau of Standards 467, Vol. II, 1952, using the reasoning suggested by J. T. Hougen, O. E. Leroi and T. C. James, J. Chem. Phys. 34, 1670 (1961). The total 30 for the quantum weight was obtained from the ground multiplet of Fe²⁺ and was split arbitrarily. The entropy values may be in error by a few entropy units due to the uncertainties in the low lying electronic levels. The principal moment of inertia is $1.5728 \times 10^{-38} \text{ g. cm.}^2$.

Heat Capacity and Entropy.

Spectroscopic constants for HCl^{35} and HCl^{37} were selected from the work of E. K. Plyler, E. D. Tidwell, Z. Elektrochem., 84, 717 (1980) and C. Hseueiler, P. Barchewitz, Compt. rend. 246, 3040 (1958). The values were adjusted to 75.5% HCl^{35} .

HIC

$$\Delta H_f^0 = -22.019 \pm 0.05 \text{ kcal. mole}^{-1}$$

Electronic Levels and Quantum Weights

$$\frac{\varepsilon_1}{\varepsilon_1 - 1}, \text{ cm.}^{-1}$$
$$r = 2989.59 \text{ cm}^{-1} \quad -1$$
$$B = 10.5884 \text{ cm}^{-1} \quad \nu = 0.3037 \text{ cm}^{-1}$$

Heat of Formation.

The selected value, Rossini's flow calorimetric measurement (1) of the direct combination of the elements, is essentially the same as that in the revised version (2) of NBS Circular 500. JANAF analyses of the more recent measurements are summarized below, while the earlier measurements have been reviewed by Rossini (1).

Experimenters	Date	Method	$\Delta H_f^{298.15}$ (kcal. mole ⁻¹)	References
Jonsson, Ambrose	1963	Comparison of HCl, H ₂ SO ₄ and SO ₂ by solution calorimetry ²	-22.14 ± 0.12	2, 3, 4, 5, 6, 7, 8, 9, 10
Lascher, et al.	1949-52	Catalytic combination in flow calorimeter	-22.10 ± 0.12	11, 12
Roth, Richter	1934	Direct combination in bomb calorimeter	-21.80 ± 0.05	13
von Wartenberg, Hanisch	1932	Direct combination in flow calorimeter	-21.80 ± 0.01	14
Rossini	1932	Direct combination in flow calorimeter	-22.063 ± 0.012	1
- - -	1922-63	ΔH_f° from e-m.f. and ΔS_f° from statistical mechanics	-22.02 ± 0.03	15, 16, 17, 18, 19, 20
Lewis	1906	ΔH_f° (kilocal. for reaction HCl(g) + 1/4 O ₂ (g) = 1/2 H ₂ O(g) + 1/2 Cl ₂ (g))	-22.30 ± 0.44	21

The direct combination values of Roth-Richter (13) and von Wartenberg - Harnisch (14) are 0.7% less negative than that of Rossini; however, all of the other methods favor the more negative value. The Roth - Richter value may be affected by errors in the measurement of the extent of reaction by HCl titration (9,22), since a set of experiments based on determination of the amount of H_2 gave a value of -22.02 kcal./mole⁻¹.

Rossmi's value is confirmed by a variety of independent methods. The solution calorimetry (3), though it is related through a complex reaction scheme, is based on species which are now quite well known. E.m.f. measurements (15,16,17,18,19,20) give $\Delta H^\circ_{298.15} = -22.735$; assuming an uncertainty of 1.0 mV. in E° , this leads to $\Delta H^\circ_{298.15} = -22.02 \pm 0.03$ (when combined with the statistical entropies). The equilibria of Lewis (625-692°K) give $\Delta H^\circ_{298.15} = -22.20 \pm 0.44$ (second law) and -22.30 ± 0.04 (third law).

CIHO

HYPOCHLOROUS ACID (HClO) (IDEAL GAS) MOL. WT. = 52.465

ΔH_f⁰ = [-22] ± 3 kcal. mole⁻¹
 ΔH_f⁰ 298.15 = [-22] ± 3 kcal. mole⁻¹
 S_{298.15} = 56.546 cal. deg.⁻¹ mole⁻¹

Vibrational Levels and Multiplicities

(μ, cm. ⁻¹)
759 (1)
1242 (1)
3626 (1)

O-H distance = 0.98 ± 0.01 Å O-Cl distance = 1.72 ± 0.04 Å H-O-Cl angle = 104° ± 3° σ = 1
 Product of moments of inertia = 4.54 × 10⁻¹¹⁷ g.² cm.⁶

Heat of Formation

I. E. Fila, K. P. Miahchenko, and N. V. Pakhomova, Zhur. Neorg. Khim. 3, 1772, 1761 (1958), report the following heats of reaction:
 ClO⁻(aq) + H⁺(aq) → HOCl(aq) ΔH_f⁰ 298.15 = -5.84 ± 0.03 kcal.
 ClO⁻(aq) + H₂O₂(aq) → Cl⁻(aq) + H₂O(l) + O₂(g) ΔH_f⁰ 298.15 = -36.93 ± 0.05 kcal.
 If the following auxiliary heats of formation are used:
 Cl⁻(aq) ΔH_f⁰ 298.15 = -40.02 kcal. mole⁻¹ (National Bureau of Standards Circ. 500, 1952)
 H₂O(l) ΔH_f⁰ 298.15 = -68.32 kcal. mole⁻¹ (National Bureau of Standards Circ. 500, 1952)
 H₂O₂(aq) ΔH_f⁰ 298.15 = -45.70 ± 0.02 kcal. mole⁻¹ (P. A. Giguère, B. G. Morissette, A. W. Olmos, and O. Knop, Can. J. Chem. 33, 804 (1955), consistent with ΔH_f⁰ 298.15 of H₂O₂(g) in this compilation)

then ΔH_f⁰ 298.15 for HOCl(aq) is found to be -31.35 kcal. mole⁻¹. From the heats of solution in water of other weak acids, ΔH_f⁰ 298.15 for HClO is estimated to be -8 ± 3 kcal. mole⁻¹. These heats yield -23 ± 3 kcal. mole⁻¹ for ΔH_f⁰ 298.15 of HOCl(g). By averaging the heats of formation of H₂O(g) and Cl₂O(g), ΔH_f⁰ 298.15 of HOCl(g) is estimated to be -20 ± 5 kcal. mole⁻¹. The value -22 ± 5 kcal. mole⁻¹ is adopted here.

Heat Capacity and Entropy

The frequencies are from K. Hadbarg and R. M. Badger, J. Chem. Phys. 19, 508 (1951), and the molecular dimensions from L. V. Gurvich and M. M. Novikov, Optica and Spectroscopy (English translation) 7, 70 (1959).

AMMONIUM CHLORIDE (NH₄Cl)

(CRYSTAL)

MOL. WT. = 53.49158

$S_{298.15}^o = 22.7 \pm 1.0$ cal. deg.⁻¹ mole⁻¹
 $T_m = 242.6^\circ\text{K.}$
 $T_c = 457.7^\circ\text{K.}$
 $T_m = 795.2^\circ\text{K.}$
 $T_d = 612^\circ\text{K.}$

Heat of Formation.

The equilibrium pressures for the reaction $\text{NH}_4\text{Cl}(c) = \text{NH}_3(g) + \text{HCl}(g)$, at 320-626°K., have been measured by many investigators. A. Smith and W. de Lange, *J. Chem. Soc.*, 2944 (1928), using the densi-tensimeter, determined the vapor pressure of $\text{NH}_4\text{Cl}(c)$ and the density of the saturated vapor simultaneously. The results obtained indicate that within the range 567-626°K. the saturated vapor completely dissociates into gaseous NH_3 and HCl . Based on this conclusion, the reported vapor pressure data were employed to evaluate the heat of dissociation of $\text{NH}_4\text{Cl}(c)$ by both the second and third law methods. The results are presented as follows.

Investigator	Temperature, °K.	Second Law Value	Third Law Value	Drift, e.u.
Smith and Calvert (1)	521.6-619.1	43.18 ± 0.08	42.11	-2.0 ± 0.2
Smith and Lange (2)	527.9-625.6	42.16 ± 0.22	42.14	-0.2 ± 0.4
Braune and Knoke (3)	525.4-615.0	42.05 ± 0.08	42.00	0.5 ± 0.2
Rodebush and Michalek (4)	471.3-557.0	42.33 ± 0.08	42.00	-0.3 ± 0.2
Wegner and Neumann (5)	530.0-612.4	42.83 ± 0.38	42.17	-4.9 ± 1.1
Markowitz and Boryta (6)	503.0-611.4	41.27 ± 0.38	42.12	1.5 ± 0.8

(1) A. Smith and R. P. Calvert, *J. Am. Chem. Soc.*, 35, 1363 (1914), using isotenoscope.
 (2) A. Smith and W. D. Lange, *J. Chem. Soc.*, 2944 (1928), using densi-tensimeter.

 (5) H. Wegner and K. Neumann, *Z. phys. Chem.*, 28, 51 (1961), torsion-effusion method.
 (6) M. M. Markowitz and D. A. Boryta, *J. Phys. Chem.*, 55, 1477 (1952), differential thermal analysis.

The value of ΔH_f^o 298.15 adopted is 42.15 ± 0.10 kcal. mole⁻¹, yielding ΔH_f^o 298.15 ($\text{NH}_4\text{Cl}, c$) = -75.8 ± 0.20 kcal. mole⁻¹. The corresponding ΔH_f^o 298.15 value evaluated from solution data, selected by V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes", NSRDS-NBS2, National Bureau of Standards, is 42.06 kcal. mole⁻¹.

Heat Capacity and Entropy.

The heat capacities (20.1-523.2°K.) of $\text{NH}_4\text{Cl}(c)$ have been measured by the following investigators: (1) R. Ewald, *Ann. Physik*, 44, 1213 (1914), 138-301°K.; (2) P. Simon, *ibid.*, 69, 241 (1922), 20.1-290.8°K.; (3) H. Klinkhardt, *ibid.*, 84, 167 (1927), 323.2-523.2°K.; (4) P. Simon, C. v. Simon and M. Rühmann, *Z. phys. Chem.*, 129, 339 (1927), 204.5-275.8°K.; (5) W. T. Ziegler and C. E. Messer, *J. Am. Chem. Soc.*, 63, 2694 (1941), 107.2-320.2°K.; (6) R. Extermann and J. Weigle, *Helv. Phys. Acta*, 15, 455 (1942), 228.2-248.2°K.; and (7) M. M. Popov and G. L. Gaiachenko, *J. Gen. Chem.*, USSR, 21, 2489 (1951), 373.2-523.2°K. These C_p data were plotted and a smooth C_p curve was drawn and adopted. The C_p values above 523°K. were obtained by graphical extrapolation of the previous C_p curve. $S_{298.15}^o$ was derived from the adopted low temperature data, based on $S_{20.1}^o = 0.114$ e.u.

Transition Data.

There are two transitions reported in the literature. The low temperature transition data (T_c and ΔH_c^o) were derived based on the heat capacity (107-320°K.) data reported by W. T. Ziegler and C. E. Messer, loc. cit., in which the other T_c values given by previous investigators were reviewed. The high temperature transition data (T_m and ΔH_m^o) were taken from H. Klinkhardt, loc. cit. However, ΔH_m^o = 1030 and ΔH_m^o = 1059.1 ± 8.0 cal. mole⁻¹ were reported by E. C. Scheffer, *Proc. Acad. Sci. Amsterdam*, 24, 1513 (1915/16), and M. M. Popov and G. L. Gaiachenko, loc. cit., respectively. M. M. Markowitz and D. A. Boryta, loc. cit. determined T_m to be 459.5 ± 0.5°K.

Melting Temperature.

T_m was obtained from H. Rasmussen, *Z. anorg. Chem.*, 114, 117 (1920), determined under pressure.

Decomposition Temperature.

The value of T_d was calculated as the temperature at which the vapor pressure of the decomposition products (NH_3 and HCl) equals 1 atm. By differential thermal analysis, T_d for $\text{NH}_4\text{Cl}(c)$ was determined to be 811.4°K. by M. M. Markowitz and D. A. Boryta, loc. cit.

1500	89.500	134.477	84.250	73.341	163.184	- 23.789

S°_{298.15} = 44.02 ± 0.04 cal. deg.⁻¹ mole⁻¹
ΔH°_f = 2.3 ± 0.2 kcal. mole⁻¹

ΔH°_f 298.15 = -70.69 ± 0.30 kcal. mole⁻¹
T_g = 513.15°K
T_d = [513]°K.

Heat of Formation.

A. A. Gilliland and W. H. Johnson, J. Research Natl. Bur. Standards 65A, 67 (1961), and M. M. Birky and L. O. Hepler, J. Phys. Chem. 64, 586 (1960), have derived the heat of formation for NH₄ClO₄(c) from solution-calorimetric measurements. Their values are -70.74 ± 0.32 and -70.63 kcal. mole⁻¹, respectively. The mean of these is adopted here.

Heat Capacity and Entropy.

B. H. Justice and E. F. Westrum, private communication, April 1961, have measured the heat capacity from 5° to 350°K. The C_p values above 350°K were extrapolated. From the partial molar entropies of NH₄⁺(aq) and ClO₄⁻(aq) and the entropy of solution, Birky and Hepler, loc. cit., calculated a value of 43.6 cal. deg.⁻¹ mole⁻¹ for S°_{298.15}. The fair agreement of this value with that derived from C_p suggests that there is no residual entropy at 0°K, as there would be if the NH₄⁺ ion had a random orientation.

Transition and Decomposition Data.

T_g and ΔH°_f were obtained (under a pressure of NH₃) by M. M. Markowitz, Foote Mineral Company, Exton, Pennsylvania (private communication, September 20, 1962). T_d was estimated from the report by M. M. Markowitz, loc. cit.

Heat of Formation

A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Ed., Chapman and Hall, London 1953, gives $23 \pm 2.3 \text{ kcal}$ for the heat of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants from K. Wieland Zeits. f. Elektrochemie 64, 761 (1960) were weighted according to their natural isotopic abundances. Rotational constants were estimated using equation III, 123 p. 108, G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York 1950. Bond length given by G. Herzberg (loc. cit.).

Heat of Formation.

The heat of formation is that adopted by O. V. Calder and W. F. Oiaque, J. Phys. Chem. 69, 2443 (1965) from an analysis of the equilibrium data of J. McMorris and D. M. Yost, J. Am. Chem. Soc. 54, 2247 (1932) and C. M. Beeson and D. M. Yost, J. Chem. Phys. 7, 44 (1939). This yielded a heat of formation of ICl(g), from which the heat of formation of ICl(c) was calculated by using the heat of vaporization determined by Calder and Oiaque loc. cit.

Heat Capacity and Entropy.

The heat capacity has been measured by Calder and Oiaque loc. cit. from 17-322°K. The entropy was calculated based on $S^\circ_{15} = 0.592$ cal. mole⁻¹ deg.⁻¹ Above 300° the heat capacity data was extrapolated smoothly.

Melting Data.

All data were measured by Calder and Oiaque loc. cit.

IODINE MONOCHLORIDE (CLI)

(LIQUID)

MOL. WT. = 162.3574

S_{298.15}° = 32.544 cal. mole⁻¹ deg.⁻¹
T_m° = 300.53°K.

ΔH_f° 298.15 = -5.72 ± 0.03 kcal. mole⁻¹
ΔH_m° = 2.773 ± 0.002 kcal. mole⁻¹

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔH_m° and the difference between H_{300.53}°-H_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity from 300.53 to 317.76°K. has been measured by G. V. Calder and W. F. Giauque, J. Phys. Chem. 69, 2443 (1965). Above 318°K. it was extrapolated in a smooth manner. The entropy was obtained in a manner analogous to the heat of formation.

Heat of Formation.

The dissociation energy from spectroscopic measurements of ICl(g) has been summarized by W. H. Evans, T. R. Munson and D. D. Wegman, J. Res. Natl. Bur. Standards, 55, 147 (1955) from which they adopt $D_0^o = 49.64 \text{ kcal. mole}^{-1}$. J. McMorris and D. M. Yost, J. Am. Chem. Soc. 54, 2247 (1932) and C. M. Beeson and D. M. Yost, J. Chem. Phys. 1, 44 (1939) studied the equilibria $\text{NOCl} = \text{NO} + 1/2 \text{ Cl}_2$ and $\text{NO} + \text{ICl} = \text{NOCl} + 1/2 \text{ I}_2(\text{g})$ from which the equilibrium constant of $\text{ICl} = 1/2 \text{ Cl}_2 + 1/2 \text{ I}_2(\text{g})$ can be obtained. O. V. Calder and W. P. Olschue, J. Phys. Chem. 69, 2443 (1965) have used 3rd law analysis to obtain $D_0^o = 49.578 \pm 0.025 \text{ kcal. mole}^{-1}$. This value was adopted yielding $\Delta H_f^o = 4.184 \pm 0.025 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The molecular and vibrational constants were obtained from G. Herzberg "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York 1950. The values were then adjusted for the normal isotopic abundance of chlorine.

POTASSIUM CHLORIDE (KCl) (CRYSTAL)

$S_{298}^{0.15} = 19.73 \pm 0.04$ cal. deg.⁻¹ mole⁻¹
 $S_{298}^{0.15} = -104.37 \pm 0.06$ kcal. mole⁻¹
 $T_m = 1044^\circ\text{K}.$
 $\Delta H_m^0 = 6.282$ kcal. mole⁻¹

Heat of Formation.

The heat of formation was calculated from the heat of hydrolysis of K(c), the heats of solution of HCl(g) and KCl(c), and the standard heat of neutralization of a strong acid and strong base. Extensive measurements are available for all these quantities. Values used in the calculation, in addition to the heat of formation for HCl(g), are summarized below.

Source	Reaction	ΔH _f ⁰ 298.15 (kcal.)
1,2,3,4	K(c) + H ₂ O(l) → KOH(∞ H ₂ O) + 1/2 H ₂ (g)	-46.966 ± 0.05
5,2,6	HCl(g) → HCl(∞ H ₂ O)	-17.88 ± 0.015
7	KCl(∞ H ₂ O) → KCl(c)	-4.115 ± 0.010
7	KOH(∞ H ₂ O) + HCl(∞ H ₂ O) → KCl(∞ H ₂ O) + H ₂ O(l)	-13.345 ± 0.025

Heat Capacity and Entropy.

Low temperature heat capacities were obtained from the data (2.8-275°K.) of W. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) A242, 487 (1957). Previous measurements scatter around the selected values and are in good agreement. These include P. G. Stralkov, E. S. Itakevich, V. N. Kostyukov, and G. G. Mirskaya (12-298°K.), Zhur. Fiz. Khim. 29, 845 (1954); K. Clusius, J. Ooldman, and A. Perlick (10-273°K.), Z. Naturforsch. 4a, 429 (1949); and J. C. Southard and R. A. Nelson (17-298°K.), J. Am. Chem. Soc. 55, 4865 (1933). For other less extensive data see the review by K. K. Kelley and E. G. King, USNM Bulletin 592, 1961. The entropy is based on the extrapolation $S_{2.8}^0 = 0.0006$ cal./deg.-mole.

High temperature values are based on enthalpy data (373-1038°K.) from T. B. Douglas, private communication, U. S. Natl. Bur. Std., May 23, 1961. These values join smoothly with the low temperature values and are in excellent agreement with the enthalpy data (673-933°K.) of S. M. Skuratov and S. A. Lapushkin, J. Gen. Chem. (USSR) 21, 2465 (1951) and the adiabatic heat capacities (334-721°K.) of A. Mustajoki, Ann. Acad. Sci. Fennicae, Series A, I, 28, 7 (1951).

Melting Data.

The melting point and heat of melting are from Douglas, loc. cit. Values of $T_m = 1043^\circ$ and $1045^\circ\text{K}.$ have been reported by E. Aukrust, B. Bjorge, H. Flood, and T. Forland, Ann. New York Acad. Sci. 79, 830 (1960) and J. W. Johnson and M. A. Predig, J. Phys. Chem. 62, 604 (1958), respectively. The heat of melting is confirmed by $\Delta H_m^0 = 6.34$ kcal./mole obtained from enthalpy data by A. S. Dworkin and M. A. Predig, J. Phys. Chem. 64, 269 (1960) and $\Delta H_m^0 = 6.4$ and 6.5 kcal./mole based on enthalpy and phase diagram studies of Aukrust et al., loc. cit., respectively.

POTASSIUM CHLORIDE (KCl)

(LIQUID)

MOL. WT. = 74.555

$\Delta H_f^{298.15} = -100.81 \text{ kcal. mole}^{-1}$
 $\Delta H_m^{298.15} = 8.282 \text{ kcal. mole}^{-1}$
 $\Delta H_v^{298.15} = 29.7 \text{ kcal. mole}^{-1}$ (equilibrium vapor)
 $\Delta H_v^{298.15} = [37.14] \text{ kcal. mole}^{-1}$ (monomer)

$S_{298.15}^{298.15} = 20.71 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 1044^\circ\text{K.}$
 $T_b = 1710^\circ\text{K.}$ (to equilibrium vapor)
 $T_b = [1750^\circ\text{K.}]$ (to monomer only)

Heat of Formation.
The heat of formation was calculated from that of the crystal by adding ΔH_m^{298} and the difference between $(H_{1044}^{298} - H_{298}^{298})$ for the crystal and liquid.

Heat Capacity and Entropy.

The constant heat capacity, 17.59 cal./deg.-mole, was derived from enthalpy data (1053-1173°K.) of T. B. Douglas, private communication, U. S. Natl. Bur. Std., May 23, 1961. This value was extrapolated above and below the experimental range. A lower value of 18.7 cal./deg.-mole was derived by A. S. Dworin, private communication, Oak Ridge National Laboratory, Dec. 1, 1964, from enthalpy data (1050-1110°K.) obtained in a heat of melting study. The entropy of the liquid was obtained in a manner analogous to the heat of formation.

Melting Data.

The melting point and heat of melting are from Douglas, loc. cit. Values of $T_m = 1043^\circ$ and 1045°K. have been reported by E. Aukrust, B. Bjorge, H. Flood, and T. Forland, Ann. New York Acad. Sci. 79, 830 (1960) and J. W. Johnson and M. A. Bredig, J. Phys. Chem. 82, 804 (1958), respectively. The heat of melting is confirmed by $\Delta H_m^{298} = 6.34 \text{ kcal./mole}$ obtained from enthalpy data by A. S. Dworin and M. A. Bredig, J. Phys. Chem. 84, 289 (1960) and $\Delta H_m^{298} = 6.4$ and 6.5 kcal./mole based on enthalpy and phase diagram studies of Aukrust et al., loc. cit., respectively.

Vaporization Data.

T_b (to equilibrium vapor) is the temperature resulting in unit total pressure based on the calculated partial pressures of KCl(g) and $K_2Cl_2(g)$. This value may be compared with boiling points of 1688° and 1690°K. observed respectively by O. Ruff and S. Mugdan, Z. anorg. allgem. Chem. 117, 147 (1921), and H. von Wartenburg and F. Albrecht, Z. Elektrochem. 27, 162 (1921). ΔH_v^{298} (equilibrium vapor) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 22.5 mole percent of dimer. According to the selected functions, the amount of dimer at lower temperatures increases gradually to about 32 mole percent at the melting point then decreases rapidly over the crystal. T_b (to monomer only) is taken as the temperature at which the calculated free energy change is zero for $KCl(l) \rightarrow KCl(g)$, while ΔH_v^{298} (monomer) is the corresponding heat of reaction.

Data on vapor pressures and dimer-monomer equilibrium are reviewed on the tables for KCl(g) and $K_2Cl_2(g)$, respectively.

Potassium Chloride (KCl)

Heat of Formation.

The heat of formation was calculated from that of the liquid based on $\Delta H_f^\circ 298.15 = 49.5 \text{ kcal./mole}$ as selected from vapor pressure analyses summarized below. Partial pressures for the monomer were obtained from data of the first four sources by combination of total vapor pressures with PVT data or with transpiration data. Mass spectrometric values (source 5) are based on temperature variation of ion intensity. These same five studies were used in selection of $\Delta H_f^\circ 298.15 = 45.0 \text{ kcal./mole}$ for the dimer-monomer equilibrium (see K_2Cl_2).

The resulting tables were tested by comparison with total pressure data over the range 819-1691°K. Dimer-monomer ratios calculated from the tables were used to convert observed total pressures to the monomer pressures which are analyzed below (sources 6-11). The results are consistent except near the boiling point where the observed pressures (sources 10 and 11) are 6-18 percent larger than those calculated. Knudsen effusion and transpiration studies over the crystal were not analyzed since they are in essential agreement with the total effusion data of source 6.

Heat Capacity and Entropy.

Rotational and vibrational constants are based on the microwave studies of P. L. Clouser and W. Oordy, Phys. Rev. 134, 4863 (1964). Earlier microwave data of A. Honig, M. Mandel, M. L. Stitt, and C. H. Townes, Phys. Rev. 95, 629 (1954) and electric resonance data of C. A. Lee, B. P. Fabricand, R. O. Carlson, and I. I. Rabi, Phys. Rev. 92, 1395 (1953) are in excellent agreement. Infrared spectra of S. A. Rice and W. Kiempfer, J. Chem. Phys. 21, 575 (1957) yield $\omega_e = 281.6 \text{ cm}^{-1}$ which is also in good agreement. The constants were adjusted to a natural isotopic composition of $24.47\% \text{ } ^{37}\text{Cl}$ and $6.8\% \text{ } ^{41}\text{K}$.

$S_{298.15}^{\circ} = 36.1 \pm 0.2$ cal. deg.⁻¹ mole⁻¹
 $T_f = 572.7^{\circ}\text{K.}$
 $T_m = 798^{\circ}\text{K.}$
 $\Delta H_f^{\circ} 0 = -100.9$ kcal. mole⁻¹
 $\Delta H_f^{\circ} 298.15 = -102.8 \pm 1.0$ kcal. mole⁻¹
 $\Delta H_c^{\circ} = 3.29$ kcal. mole⁻¹
 $\Delta H_m^{\circ} = \text{Unknown}$

Heat of Formation.

The heat of decomposition of KClO₄(c) to KCl(c) and O₂(g) was measured by W. H. Johnson and A. A. Gilliland, J. Res. Natl. Bur. Std. 55A, 65 (1961), yielding $\Delta H_f^{\circ} 298.15 = -103.22 \pm 0.15$ kcal. mole⁻¹. K. A. Hofmann and P. H. Martin, Sitzber. preuss. Akad. Wiss. Physik. math. Kl. 448 (1932), burned a mixture of paraffin and potassium perchlorate and obtained $\Delta E_{298.15} = -1.73$ kcal. mole⁻¹ for the constant volume process corresponding to the reaction: $\text{KClO}_4(\text{c}) = \text{KCl}(\text{c}) + 2\text{O}_2(\text{g})$. Correction of their value for $\Delta(\text{PV})$ gives $\Delta H_f^{\circ} 298.15 = -0.55$ kcal. mole⁻¹ which agrees reasonably well to the corresponding value, -0.96 ± 0.10 kcal. mole⁻¹, reported by W. H. Johnson and A. A. Gilliland, loc. cit. However, for the same reaction, $\Delta H_f^{\circ} 298.15 = -2.55 \pm 0.18$ kcal. mole⁻¹ was determined by S. M. Skuratov, A. P. Vorob'ev and N. M. Privolova, Russ. J. Inorg. Chem. 7, 343 (1962). They measured this quantity by two different methods which gave concordant results. The value of $\Delta H_f^{\circ} 298.15$ reported was -101.9 ± 0.2 kcal. mole⁻¹. The value used here is the average of these four results. M. Berthelot and P. Vieille, Ann. chim. et phys. [5] 21, 225 (1882) determined the difference between the heat of explosion of ammonium picrate and that of an ammonium picrate-potassium perchlorate mixture, and also the difference between the heat of explosion of potassium picrate and that of a potassium picrate-potassium perchlorate mixture. They obtained $\Delta H_f^{\circ} = 7.5$ kcal. mole⁻¹ for the reaction $\text{KClO}_4(\text{c}) = \text{KCl}(\text{c}) + 2\text{O}_2(\text{g})$. From that the value of $\Delta H_f^{\circ} 298.15$ was calculated to be -111.9 kcal. mole⁻¹. This value was not used.

Heat Capacity and Entropy.

The low temperature heat capacities (12.53-238.07°K.) were measured by W. M. Latimer and J. E. Ahlberg, J. Am. Chem. Soc. 52, 549 (1930). The heat capacities above 298°K. were estimated by comparison with those of NaClO₄(c). $S_{298.15}^{\circ}$ was reported by K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592 (1961), based on the low temperature heat capacities measured by W. M. Latimer and J. E. Ahlberg, loc. cit., using $S_{12.53}^{\circ}$ (extrap.) = 0.14 cal. deg.⁻¹ mole⁻¹.

Transition Data.

T_f and ΔH_f° were obtained from the National Bureau of Standards, Circ. 500, "Selected Values of Chemical Thermodynamic Properties," by F. D. Rossini, et al., 1952.

Temperature of Melting.

T_m was taken from Bulletin of the National Research Council, No. 118, "Data on Chemicals for Ceramic Use," June 1949.

LITHIUM CHLORIDE (LiCl)

(CRYSTAL)

MOL. WT. = 42.397

$$\Delta H_f^\circ 298.15 = -97.578 \pm 0.273 \text{ kcal mole}^{-1}$$

$$S^\circ_{298.15} = 14.173 \pm 0.015 \text{ cal deg}^{-1} \text{ mole}^{-1}$$

$$T_m = 883 \pm 2^\circ \text{K}$$

Heat of Formation

The heat of formation was obtained as follows:

- (1) $\text{LiOH} \cdot 100\text{H}_2\text{O} + \text{HCl} \cdot 100\text{H}_2\text{O} \rightarrow \text{LiCl} \cdot 20\text{H}_2\text{O}$
T. W. Richards and A. W. Rowe, *J. Am. Chem. Soc.*, **44**, 684 (1922).
- (2) $\text{Li}(c) + 100\text{H}_2\text{O}(l) \rightarrow \text{LiOH} \cdot 100\text{H}_2\text{O} + 1/2 \text{H}_2(g)$
S. R. Gunn and L. G. Green, *J. Am. Chem. Soc.*, **80**, 4782 (1958).
- (3) $\text{LiOH} \cdot 100\text{H}_2\text{O} \rightarrow \text{LiOH} \cdot 100\text{H}_2\text{O} + 900\text{H}_2\text{O}(l)$
T. W. Richards and A. W. Rowe, *J. Am. Chem. Soc.*, **43**, 770 (1921).
- (4) $1/2 \text{H}_2(g) + 1/2 \text{Cl}_2(g) \rightarrow \text{HCl}(g)$
JANAF Tables.
- (5) $\text{HCl}(g) + 100\text{H}_2\text{O}(l) \rightarrow \text{HCl} \cdot 100\text{H}_2\text{O}$
C. M. Slansky, *J. Am. Chem. Soc.*, **62**, 2430 (1940), and
J. M. Sturtevant, *J. Am. Chem. Soc.*, **62**, 3265 (1940).
- (6) $\text{LiCl} \cdot 20\text{H}_2\text{O} \rightarrow \text{LiCl}(c) + 20\text{H}_2\text{O}(l)$
E. Lange and F. Dürr, *Z. phys. Chem.*, **121**, 361 (1926).

$$(1) + (2) + (3) + (4) + (5) + (6) \text{ gives Li}(c) + 1/2 \text{Cl}_2(g) \rightarrow \text{LiCl}(c)$$

A direct calorimetric determination by H. Siemensen and U. Siemensen, *Z. Electrochem.*, **56**, 643 (1952) gave -94.8 ± 0.6 kcal mole⁻¹. However, the solution route was thought to be inherently more accurate and was adopted.

Heat Capacity and Entropy

The heat capacity between 15° and 325°K has been measured by D. A. Shirley, *J. Am. Chem. Soc.*, **82**, 3841 (1960) and by F. L. Oetting, W. E. Hutton and G. C. Sinke, unpublished work, Thermal Laboratory, Dow Chemical Company. The two sets of data are in substantial agreement and were plotted together and used to evaluate the entropy at 298°. The extrapolation to 0°K was done assuming a T³ law and yielded S₁₅ = 0.019 e.u. Above 298° T. B. Douglas, J. L. Dever and A. W. Harman, quoted in Natl. Bur. Standards Report 6297, have made enthalpy measurements to 1200°K. E. N. Rodigina, K. Z. Gornelski, and V. F. Luginina, *Zhur. Neorg. Khim.*, **4**, 975 (1959) also made enthalpy determinations to 1100°K. These two sets of measurements were averaged and joined smoothly to the low temperature values.

Melting and Transition Data

The melting point has been reported as follows: 880°K., Douglas et al., loc. cit.; 883°K., Rodigina et al., loc. cit.; 883°K., H. M. Haendler, P. S. Bennett, and C. M. Wheeler, *J. Electrochem. Soc.*, **106**, 264 (1959); 879°K., H. Flood, O. Fyke and S. Urnes, *Z. Electrochem.*, **59**, 364 (1955); 879°K., H. von Wartenberg and H. Schulz, *Z. Electrochem.*, **27**, 588 (1921). The highest value of 883°K. was taken as representing the most pure samples. At this temperature the enthalpy equations of Douglas et al. yield a heat of fusion of 4.718 kcal mole⁻¹, those of Rodigina et al., 4.669 kcal mole⁻¹. A. S. Dworkin and M. A. Bredig, *J. Phys. Chem.*, **64**, 263 (1960) report a value of 4.76 ± 0.10 kcal mole⁻¹ and quote 4.83 kcal mole⁻¹ from a private communication from D. F. Smith. The average value ΔH_m = 4.74 ± 0.10 kcal mole⁻¹ was adopted.

A transition at 838°K has been reported by Kislova and Bergman, *Russ. J. Inorg. Chem.*, **5**, 1210 (1960) but is not supported by the enthalpy measurements quoted above.

LITHIUM CHLORIDE (LiCl)

(LIQUID)

MOL. WT. = 42.397

$$\Delta H_f^\circ 298.15 = -93.394 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^\circ = 16.745 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^\circ = 4.74 \pm 0.10 \text{ kcal. mole}^{-1}$$

$$T_m = 883 \pm 2^\circ \text{K}$$

$$T_b(\text{monomeric gas}) = 1701^\circ \text{K}$$

$$T_b(\text{equilibrium mixture}) = 1655^\circ \text{K}$$

Heat of Formation.

Obtained from that of the crystal by adding ΔH_m and $H_{883}^\circ - H_{298}^\circ(c)$ and subtracting $H_{883}^\circ - H_{298}^\circ(l)$.

Heat Capacity and Entropy.

The heat capacity from the melting point to 1100°K and 1200°K has been reported by E. N. Rodigina, K. Z. Omel'nik, and V. P. Luginina, Zhur. Neorg. Khim. 4, 975 (1959) and T. B. Douglas, J. L. Dever, and A. W. Harman, quoted in Natl. Bur. of Standards Report 6297. The equation given by the former authors for the enthalpy of the liquid does not agree with their measurements and has been replaced by $H_m - H_{298.15} = 16.000T - 1.5 \times 10^{-5}T^2 - 2279 \text{ cal. mole}^{-1}$, which fits to $\pm 0.5\%$. The two sets of results were averaged and the equations were assumed to hold up to the normal boiling point. The entropy was calculated from that of the crystal in a manner analogous to the heat of formation.

Melting.

See table for crystal.

Boiling.

The equilibrium boiling point was taken from H. von Wartenburg and H. Schultz, Z. Electrochem. 27, 568 (1921) and the boiling point of the monomeric gas is defined as the temperature at which it reaches 1 atm. pressure. This was obtained from the free energy crossover between liquid and monomeric gas. The heat of vaporization to the monomeric gas was found from the tables to be 39.8 kcal. mole⁻¹.

LITHIUM CHLORIDE (LiCl)

(IDEAL GAS)

MOL. WT. = 42.397

 $\Delta H_f^\circ = -46.742 \text{ kcal. mole}^{-1}$ $\Delta F_f^\circ = -46.742 \text{ kcal. mole}^{-1}$ Ground State Configuration $1\sum$ $5^2 98.15 = 50.864 \text{ cal. deg}^{-1} \text{ mole}^{-1}$ $\omega_e = 641.1 \pm 3.0 \text{ cm}^{-1}$ $\omega_{e^*} = 4.2 \pm 0.3 \text{ cm}^{-1}$ $\sigma = 1$ $B_e = 0.7053 \text{ cm}^{-1}$ $\alpha_e = 0.0067 \text{ cm}^{-1}$ $r_e = 2.022 \text{ \AA}$

Heat of Formation.

W. Klemperer, W. G. Norris, A. Büchler and A. G. Emalle, *J. Chem. Phys.* **33**, 1534 (1960) quote a private communication from W. H. Evans at the National Bureau of Standards giving $D_0 = 4.85 \text{ e.v.}$, which corresponds to $\Delta H_f^\circ = -45.3 \pm 2.4 \text{ kcal. mole}^{-1}$. A third law analysis of the vapor pressure data of An. N. Nesmeyanov and L. A. Sazonov, *Zhur. Neorg. Khim.* **5**, 231 (1960) in conjunction with the relative concentration of monomer, dimer, and trimer at 870°K from the work of R. C. Miller and P. Kusch, *J. Chem. Phys.* **25**, 860 (1956) and **27**, 991 (1957) leads to a monomer heat of sublimation at 298° of $52.56 \text{ kcal. mole}^{-1}$, this gives $\Delta H_f^\circ 298.15 = -45.02 \text{ kcal. mole}^{-1}$. These values lead, however, to partial vapor pressures of the monomer which are less than half of the total vapor pressure near the boiling point. From the data of Miller and Kusch loc. cit. it would be expected that the monomer would be the predominant species near the boiling point, a fact also substantiated by the work of C. Beusman, *AEC Report ORNL-2223* (1957), on the average molecular weight of the vapor. Thus it was decided to change the heat of sublimation as to give the correct normal boiling point and vapor pressures in the region 1400-1600°K and to approximate the relative concentrations of monomer, dimer, and trimer as found by Miller and Kusch at 870°K. A monomer heat of sublimation at 298° of $50.8 \text{ kcal. mole}^{-1}$ was chosen, which gives $\Delta H_f^\circ 298.15 = -46.778 \text{ kcal. mole}^{-1}$. The normal boiling point was taken as 1656°K as determined by H. von Wartenburg and H. Schulz, *Z. Elektrochem.* **27**, 568 (1921) and the boiling point of $\text{LiCl}(g)$ was found as 1701°K from the free energy crossover between liquid and gas.

Heat Capacity and Entropy.

The spectroscopic constants were taken from Klemperer et al. loc. cit. The value of α_e was calculated from the value of B_e given by the Rittner potential function and the equation given by Klemperer et al. The value of r_e was taken from the Natl. Bur. of Standards Report 6297 (1959).

LiClO₄

MOL. WT. = 106.397

(CRYSTAL)

LITHIUM PERCHLORATE (LiClO₄)

ΔH_f° = Unknown

S°_{298.15} = [30 ± 1] cal. deg.⁻¹ mole⁻¹

ΔH_f° = [7] kcal. mole⁻¹

Heat of Formation.

The heats of reaction (ΔH_r°) involving LiClO₄(c) has been determined by several investigators as follows:

Investigator	Chemical Reaction	ΔH _r ° 298.15, kcal. mole ⁻¹	ΔH _f ° 298.15, kcal. mole ⁻¹
Gilliland and Johnson (1)	LiClO ₄ (c) + KCl(c) → LiCl(c) + KClO ₄ (c)	-5.86 ± 0.06	-90.34
Markowitz, et al. (2)	LiOH(225H ₂ O) + HClO ₄ (225H ₂ O) → LiClO ₄ (451H ₂ O) + H ₂ O(l)	-13.54 ± 0.09	-91.7
Birky and Hepler (3)	LiClO ₄ (c) → Li ⁺ (aq.) + ClO ₄ ⁻ (aq.)	-6.31 ± 0.13	-91.11

(1) A. A. Gilliland and W. H. Johnson, J. Res. Natl. Bur. Std. 65A, 67 (1961).

(2) M. M. Markowitz, R. P. Herra and H. Stewart, Jr., J. Phys. Chem. 63, 1325 (1959).

(3) M. M. Birky and L. G. Hepler, J. Phys. Chem. 64, 686 (1960).

The adopted value, ΔH_f° 298.15 = -91.0 kcal. mole⁻¹, for LiClO₄(c) is the weighted average of the three values listed.

Heat Capacity and Entropy:

Heat capacities and S°_{298.15} were estimated by comparison with those of KClO₄(c).

Melting Data.

T_m was obtained from T. W. Richards and H. H. Willard, J. Am. Chem. Soc., 32, 4 (1910). The value of ΔH_m° 509 was estimated by comparison with the value, ΔH_m° 528 = 5.4 kcal. mole⁻¹, for NaClO₃(c) reported by K. K. Kelley, Contribution to the Data on Theoretical Metallurgy, XIII. High-Temperature Heat-Content, Heat-Capacity and Entropy Data for the Elements and Inorganic Compounds, U. S. Bur. Mines Bull. 584 (1960).

Dec. 31, 1960; Mar. 31, 1964

LITHIUM PERCHLORATE (LiClO₄)

(LIQUID)

MOL. WT. = 106.397

$S^\circ_{298.15} = [39.245]$ cal. deg.⁻¹ mole⁻¹
 $T_m = 509^\circ\text{K.}$
 $\Delta H^\circ_f 298.15 = [-85.574]$ cal. deg.⁻¹ mole⁻¹
 $\Delta G^\circ_m = [7]$ kcal. mole⁻¹

Heat of Formation.

$\Delta H^\circ_f 298.15(1)$ was obtained from $\Delta H^\circ_f 298.15(c)$ by adding ΔH°_m and the difference between $H^\circ_{370.6}$ and $H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

C_p for LiClO₄(l) was estimated by comparison with that for NaClO₃(l). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

The melting temperature (T_m) was obtained from T. W. Richards and H. H. Willard, J. Am. Chem. Soc., **32**, 4 (1910). The value of ΔH°_m 509 was estimated by comparison with the value, ΔH°_m 528 = 5.4 kcal. mole⁻¹, for NaClO₃(c) reported by K. K. Kelley, Contribution to the Data on Theoretical Metallurgy, XIII. High-Temperature Heat-Content, Heat-Capacity and Entropy Data for the Elements and Inorganic Compounds, U. S. Bur. Mines Bull. 584 (1960).

Magnesium Monochloride (MgCl)

(Ideal Gas) Mol. wt. = 59.765

Dec. 31, 1960; Mar. 31, 1966

MOL. WT. = 59.765

(IDEAL GAS)

MAGNESIUM MONOCHLORIDE (MgCl)

Ground State Configuration $\sum$ $\Delta H_f^0 = -10.34 \pm 10$ kcal. mole⁻¹

$S_{298.15}^0 = 55.760$ cal. deg.⁻¹ mole⁻¹ $\Delta H_f^0 298.15 = -10.4 \pm 10$ kcal. mole⁻¹

Electronic Levels and Quantum Weights

$$\frac{\epsilon_l, \text{cm.}^{-1}}{0} \frac{g_l}{2}$$

$\omega_e x_e = 2.02$ cm.⁻¹ $\sigma = 1$

$\alpha_e = [0.0014]$ cm.⁻¹ $r_e = 2.199 \text{ \AA}$

$B_e = [0.2417]$ cm.⁻¹

Heat of Formation.

The heat of formation is calculated from $D_0^0 = 3.2$ e.v. reported by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Co., Inc., New York, 1950. $D_0^0 = 2.7 \pm 0.7$ e.v. reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", 2nd Edn., Chapman and Hall, London, 1953, yields $\Delta H_f^0 298$ (MgCl, g) = 1.0 ± 16 kcal. mole⁻¹.

Heat Capacity and Entropy.

Spectroscopic constants were reported by Herzberg loc. cit. and adjusted for natural isotopic abundance. The bond length was reported by E. Morgan and R. F. Barrow, Nature 192, 1182, (1961). B_e and α_e were estimated by the method suggested by Herzberg loc. cit. The moment of inertia (I) is $11.578 \times 10^{-59} \text{ g. cm.}^2$

(IDEAL GAS)

MOL. WT. = 65.4591

NITROSYL CHLORIDE (NOCl)

Point Group C_sS_{298.15} = 82.53 cal. deg⁻¹ mole⁻¹ΔH_f^o 298.15 = 12.37 ± 0.2 kcal. mole⁻¹

Ground State Quantum Weight = 1

Vibrational Frequencies & Degeneracies

ω, cm⁻¹

1800 (1)

594.9 (1)

331.5 (1)

Bond Distance: N-Cl = 1.95 ± 0.06 Å

Bond Angle: Cl-N-O = 114 ± 3°

Product of the Moments of Inertia: I_AI_BI_C = 2.278778 X 10⁻¹¹⁵ g.³ cm.⁶

σ = 1

Heat of Formation.

The equilibrium constants for the reaction 2NOCl(g) = 2NO(g) + Cl₂(g) have been measured in the temperature range from 372° to 491°K. by C. M. Beeson and D. M. Yost, J. Chem. Phys. **2**, 44 (1936). Using the reported equilibrium constants, the heat of reaction (ΔH_f^o 298) has been calculated by both the second and the third law methods, as 18.33 ± 0.1 kcal. mole⁻¹ and 18.42 ± 0.1 kcal. mole⁻¹, respectively. The third law value is adopted to calculate the heat of formation of nitrosyl chloride (g) as ΔH_f^o 298 = 12.37 ± 0.2 kcal. mole⁻¹.

Heat Capacity and Entropy.

The selected bond distances and angle were obtained from the microwave measurements by J. D. Rogers and D. Williams, J. Chem. Phys. **34**, 2195 (1961). J. A. A. Ketelaar and K. J. Palmer, J. Am. Chem. Soc. **59**, 2629 (1937), reported the bond distance N-Cl = 1.95 Å and the angle O-N-Cl = 116° by the electron diffraction method. These two are in good agreement. The three principal moments of inertia are I_A = 0.995 X 10⁻⁵⁹, I_B = 14.685 X 10⁻⁵⁹ and I_C = 15.678 X 10⁻⁵⁹ g. cm². The selected vibrational frequencies which were obtained from the infrared spectrum by L. Landau and W. H. Fletcher, J. Mol. Spectry. **4**, 276 (1960), have been modified to natural isotopic mixture. W. G. Burns and J. J. Bernatkin, J. Chem. Phys. **18**, 1669 (1950), reported the vibrational frequencies as 1799, 592 and 332 cm⁻¹.

J. S. Gordon, J. Chem. Eng. Data **7**, 82 (1962), has calculated the thermodynamic functions from 298.15° to 6000°K. by the method of R. E. Fennington and K. A. Kobe, J. Chem. Phys. **22**, 1442 (1954), which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from Landau and Fletcher, loc. cit., and J. D. Rogers, W. J. Pietenpol and D. Williams, Phys. Rev. **83**, 431 (1951). These calculated functions have been adopted in the tabulation. Below 298°K. the rigid-rotator harmonic oscillator method was used to calculate the functions.

367 (1)	851 (1)

Bond Distances: N-Cl = 1.83 Å

Bond Angles: O-N-O = 129.5°

Product of Moments of Inertia: I_AI_BI_C = 2.36698 X 10⁻¹¹⁴ g.³ cm.⁶

Heat of Formation:

The selected heat of formation was obtained from the recalculation of the heat of reaction ClNO₂ + NO = ClNO + NO₂ which has been measured calorimetrically as -9.27 kcal. mole⁻¹ by J. Ray and R. Ogg, Jr., J. Chem. Phys. 31, 168 (1959). Not only the thermal effects of 2NO₂ = N₂O₄ but also NO + NO₂ = N₂O₃ (a minor one) have been considered in calculation. Using all JANAP auxiliary data for ClNO, NO, NO₂, N₂O₃ and N₂O₄, the recalculation gives ΔH_f⁰ 298 = 2.90 ± 0.4 kcal. mole⁻¹ for NO₂Cl(g). For the reaction ClNO + N₂O₅ = ClNO₂ + 2NO₂ also measured by Ray and Ogg, loc. cit., the recalculation gives ΔH_f⁰ 298 (NO₂Cl, g) = 2.56 ± 0.4 kcal. mole⁻¹.

H. Martin and E. Koshlein, Z. physik. Chem. 17, 375 (1958), have determined kinetically the heat of reaction, ΔH_f⁰ 273.15 = 3.10 kcal. mole⁻¹, for the reaction NO₂ + NOCl = NO + NO₂Cl which gives ΔH_f⁰ 298 = 1.90 ± 1 kcal. mole⁻¹ for NO₂Cl(g). H. Cordas and H. Johnston, J. Am. Chem. Soc., 76, 4284 (1954), have also determined kinetically the ΔH_f⁰ = 29.5 kcal. mole⁻¹ for the reaction NO₂Cl = NO₂ + Cl which gives ΔH_f⁰ 298 = 6.3 ± 0.3 kcal. mole⁻¹.

Heat Capacity and Entropy.

The selected bond distances and bond angles were obtained from microwave spectrum studies by L. Clayton, Q. Williams and T. L. Weatherly, J. Chem. Phys. 30, 1328 (1959). D. J. Millen and K. M. Simmott, J. Chem. Soc. 350 (1958), reported bond distance N-Cl = 1.840 Å, N-O = 1.202 Å and angle ONO = 130° 35' from the microwave measurement. These two are in good agreement.

The selected vibrational frequencies were obtained from infrared and Raman spectrum measurements by R. Ryerson and M. K. Wilson, J. Chem. Phys. 22, 2000 (1954). However, the assignment of the fundamental frequencies has been revised by R. E. Dodd, J. A. Rolfe and L. A. Woodward, Trans. Faraday Soc. 52, 145 (1956), and Y. Morino and T. Tanaka, J. Mol. Spectry. 15, 179 (1965). Morino and Tanaka's assignment was adopted. The three principal moments of inertia are I_A = 6.3558 X 10⁻³⁹, I_B = 16.3609 X 10⁻³⁹ and I_C = 22.7267 X 10⁻³⁹ g.² cm.²

$$\Delta H_f^0 = -98.16 \pm 0.08 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{298.15} = -98.26 \pm 0.08 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = 6.73 \pm 0.04 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 17.24 \pm 0.05 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1073.8 \pm 1.0^\circ \text{K.}$$

Heat of Formation.

The heat of formation is based on $\Delta H_f^{298.15} = -57.39$ and $-39.95 \text{ kcal. mole}^{-1}$ for $\text{Na}^+(\infty \text{H}_2\text{O})$ and $\text{Cl}^-(\infty \text{H}_2\text{O})$, respectively, and on the heat of solution $\Delta H_{\text{sol}}^{298.15} = 0.922 \text{ kcal. mole}^{-1}$ for NaCl. These values were reported in a private communication from D. D. Wagman, National Bureau of Standards, June, 1964.

Heat Capacity and Entropy.

The low temperature values are based on the heat capacities (3-266°K) reported by T. H. K. Barron, A. J. Leadbetter, J. A. Morrison, Proc. Roy. Soc. (London) A279 (1376), 62 (1964). The earlier work of K. Clausius, J. Goldman, A. Parlick, Z. Naturforsch. 4g, 424 (1949), results in a slightly higher entropy ($S_{298.15}^0 = 17.33 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$) but a lower heat capacity at room temperature ($C_p^{298.15} = 11.9 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$). The high temperature values have been obtained by reanalysis of the enthalpies (672 - 1279°K) of R. Dawson, E. B. Brackett, T. E. Brackett, J. Phys. Chem. 67, 1669 (1963), using the new value for $C_p^{298.15}$. The resulting tables agree within $\pm 0.1 \text{ kcal.}$ with the enthalpies (812 - 1058°K) of W. A. Roth, W. Bertram, Z. Elektrochem. 35, 38 (1929). The enthalpies (540 - 1037°K) of A. Magnus, Physik. Zeitschr. 14, 5 (1913), agree well at the lower temperatures but are about 0.3 kcal. smaller near the melting point.

Melting Data.

The melting temperature was taken from Dawson, Brackett and Brackett, loc. cit., and the heat of melting was obtained by reanalysis of their crystal and liquid enthalpies. Values of $T_m = 1073^\circ \text{K.}$ and $\Delta H_m^0 = 6.69 \pm 0.06 \text{ kcal. mole}^{-1}$ were reported by A. S. Dworkin, M. A. Bredig, J. Phys. Chem. 64, 269 (1960).

Heat of Sublimation.

The vapor in equilibrium with NaCl contains both monomeric and polymeric forms (for details see the tables for NaCl gases).

$$S_{298.15}^{\circ} = [22.719] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_{f, 298.15}^{\circ} = [-92.237] \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{\circ} = 6.73 \pm 0.04 \text{ kcal. mole}^{-1}$$

$$T_m = 1073.8 \pm 1.0^{\circ}\text{K.}$$

Heat of Formation.

$\Delta H_f^{\circ}(1)$ was obtained from $\Delta H_f^{\circ}(c)$ by addition of ΔH_m° and the difference between ($H_{1073.8}^{\circ} - H_{298.15}^{\circ}$) for the crystal and liquid.

Heat Capacity and Entropy.

These were obtained by analysis of the enthalpies (1076 - 1279°K) of R. Dawson, E. B. Brackett, T. E. Brackett, J. Phys. Chem. 67, 1669 (1963). The heat capacity was extrapolated to a constant value of 16.0 at the higher temperatures. A glass transition was assumed at 800°K. and below this temperature C_p° was taken equal to that of the crystal.

Melting Data.

The melting temperature was taken from Dawson, Brackett and Brackett, loc. cit., and the heat of melting was obtained by reanalysis of their crystal and liquid enthalpies. Values of $T_m = 1073^{\circ}\text{K.}$ and $\Delta H_m^{\circ} = 6.69 \pm 0.06 \text{ kcal. mole}^{-1}$ were reported by A. S. Dworkin, M. A. Bredig, J. Phys. Chem. 64, 269 (1960).

Heat of Sublimation.

The vapor in equilibrium with NaCl contains both monomeric and polymeric forms (for details see the tables for NaCl gases).

Heat of Formation.

The heat of formation is based on a heat of sublimation ΔH_g^0 298.15 = 54.9 kcal. mole⁻¹ obtained from the more consistent sets of vapor pressure data by correction for the presence of dimer. Observed vapor pressures were converted to monomer pressures by use of dimer-monomer ratios calculated from JANAF free energy functions and ΔH_f^0 298.15 = 48.6 kcal. for the reaction $(NaCl)_2(g) \rightarrow 2NaCl(g)$. Higher polymeric species were neglected. Analyses of the resulting monomer pressures are summarized below.

Source	Temperature Range (°K)	Heat of Sublimation ΔH_g^0 298.15 (kcal. mole ⁻¹)
Neameyanov & Sazonov(1)	743 - 948*	54.35
Zimm & Mayer(2)	760 - 897*	55.15

Heat Capacity and Entropy.

The molecular constants are based on molecular beam studies of the rotational spectra by Clouser and Gordy, Bull. Am. Phys. Soc. B, 328 (1963) and on microwave studies by Honig, Mandel, Stinch and Townes, Phys. Rev. 96, 629 (1954).

The infrared spectra of Rice and Kempner, J. Chem. Phys. 21, 573 (1957) give a frequency in close agreement (368 cm.⁻¹).

A. A. Gilliland and W. H. Johnson, J. Res. Natl. Bur. Std. 65A, 67 (1961) measured the heat of solution of NaClO₄(c) and gave ΔH_f° 298.15 = -91.48 ± 0.22 kcal. mole⁻¹ for NaClO₄(c). The heat of dilution of NaClO₄(c) was measured by C. E. Vanderve and J. A. Sorenson, J. Phys. Chem. 67, 285 (1963). The data led to ΔH_f° 298.15 = -91.484 kcal. mole⁻¹ which agrees very well with the data reported by A. A. Gilliland and W. H. Johnson, loc. cit. The value of ΔH_f° 298.15 was reported to be -92.18 kcal. mole⁻¹ in the National Bureau of Standards Circ. 500, "Selected Values of Chemical Thermodynamic Properties," 1952, based upon the data prior to 1950. A. F. Vorob'ev, et al., Proc. Acad. Sci. USSR, 135, 1439 (1960) measured the heat of decomposition of NaClO₄(c) into NaCl(c) and O₂(g) and gave ΔH_r° 298.15 = -90.68 ± 0.3 kcal. mole⁻¹ for NaClO₄(c). This value reported by A. A. Gilliland and W. H. Johnson, loc. cit. was used.

Heat Capacity and Entropy.

Heat capacities and S° 298.15 were estimated by comparison with those for NaClO₃(c) and KClO₄(c), respectively.

Transition Data.

T_t was reported in the National Bureau of Standards, Circ. 500, loc. cit. ΔH_t° was estimated from that for KClO₄(c).

Temperature of Melting.

T_m was obtained from Bulletin of the National Research Council, No. 118, "Data on Chemicals for Ceramic Use," June 1949.

June 30, 1961

$D_0 = 63.33 \pm 0.03$ kcal. mole⁻¹
 $\Delta H_f^\circ 298.15 = 24.19 \pm 0.05$ kcal. mole⁻¹
 $S^\circ 298.15 = 54.145$ cal. deg.⁻¹ mole⁻¹
Ground State Configuration $2\Pi_{3/2}$

Electronic Level and Multiplicity

$$\frac{E_i, \text{ cm.}^{-1}}{0} \quad \frac{g_i}{4}$$

$\omega_e x_e = 7.5$ cm.⁻¹
 $\omega_e = 866 \pm 26$ cm.⁻¹
 $B_e = 0.645(3)$
 $\alpha_e = [0.0069]$ cm.⁻¹
 $D_e = 2(2) \times 10^{-6}$ cm.⁻¹
 $r_e = 1.546 \text{ \AA}$
 $\sigma = 1$

Heat of Formation

R. A. Durie and D. A. Ramsay, Can. J. Phys. 35, 35 (1958) and G. Herzberg and D. A. Ramsay, Disc. Faraday Soc. 9, 80 (1950) report $D_0 = 22152 \pm 10$ cm.⁻¹ and $D_0 = 22141$ cm.⁻¹ respectively, and these values have been averaged.

Heat Capacity and Entropy

The spectroscopic constants are for the natural mixture of isotopes and are based on measurements by Durie and Ramsay, loc. cit., and by G. Porter, Disc. Faraday Soc. 9, 60 (1950). α_e has been estimated by the method given by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Company, Inc., New York, 1950, p. 108.

Titanium Oxide Chloride (TiOCl)

TITANIUM OXIDE CHLORIDE (TiOCl)

(IDEAL GAS)

MOL. WT. = 99.357

Point Group $[C_{\infty v}]$
 $\Delta F^\circ_0 = [-59.0] \text{ kcal. mole}^{-1}$
 $S^\circ_{298.15} = [62.992] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta F^\circ_{298.15} = [-58.4] \text{ kcal. mole}^{-1}$
 Ground State Quantum Weight = [2]

Vibrotional Frequencies and Degeneracies

ω , cm. ⁻¹	
[890] (1)	
[230] (2)	
[490] (1)	

Bond Distances: O-Ti = [1.62] Å Ti-F = [2.17] Å

Bond Angles: O-Ti-Cl = [180°] $\sigma = 1$ Rotational Constant: $B_0 = [0.09225] \text{ cm.}^{-1}$

Heat of Formation.

ΔH°_0 was estimated as -58 kcal. mole⁻¹ by J. S. Gordon, AstroSystems, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. $\Delta H^\circ_{298.15}$ was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. Principal moments were: $I_A = I_C = 30.34 \times 10^{-39} \text{ g. cm.}^2$

Heat of Formation

M. H. Evans, T. R. Munson, and D. D. Wagman, J. Research Natl. Bur. Standards 55, 147 (1955), have evaluated the available data and chosen the above value.

Heat Capacity and Entropy

J. S. Gordon, private communication, February, 1961, has calculated the thermodynamic functions from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from J. B. Coon and E. Ortiz, J. Molec. Spectros. 1, 61 (1957). The functions below 298.15°K have been calculated for a rigidly rotating harmonic oscillator.

0	[3]

$$\omega_e = [472] \text{ cm.}^{-1}$$

$$\omega_e x_e = [1.89] \text{ cm.}^{-1}$$

$$\sigma = 1$$

$$\alpha_e = [0.00098]$$

$$r_e = [2.04] \text{ \AA}$$

Heat of Formation.

The selected $\Delta H_f^0 298.15$ was calculated by assuming that the second and third bonds in $\text{PCl}_3(\text{g})$ are of equal strength, and that the first bond has a strength 20% greater than the other two. These assumptions were used by C. B. Henderson and R. S. Scheffer, Survey of Thermochemical Data, Atlantic Research Corporation, Alexandria, Virginia, January 1960. The selected $\Delta H_f^0 298.15$ was calculated using these bond strengths and auxiliary data from JANAP Tables.

A $\Delta H_f^0 298.15$, 40 kcal. mole⁻¹, estimated by C. J. O'Brien and J. R. Perrin, The Marquardt Corporation and J. Perrine, Olin Mathieson Chemical Corp., "Estimation of the Heats of Formation of Gaseous Combustion Product Molecules," WSC/CI Paper 59-4, October, 1959, when adjusted to the red V phosphorus reference state becomes [44.2] kcal. mole⁻¹.

A. A. Sandoval, H. C. Moser, and R. W. Kiser, J. Phys. Chem. 67, 124, (1963) have calculated a $\Delta H_f^0 298.15$ for PCl from an appearance potential. They selected the process $\text{PCl}_3 \rightarrow \text{Cl}^+ + \text{e}^- + \text{PCl} + \text{Cl}$ to explain this potential rather than the process $\text{PCl}_3 \rightarrow \text{Cl}^+ + \text{e}^- + \text{P} + \text{Cl}_2$. The reason for their selection was a calculated $\Delta H_f^0(\text{Cl})$, 10 kcal. lower than the literature value (See National Bureau of Standards "Selected Values of Chemical Thermodynamic Properties" Circular 500). Use of the JANAP $\Delta H_f^0 298.15$ for PCl_3 eliminates this difference.

Therefore, the process of the reported appearance potential would apparently be the second process which does not involve the neutral PCl radical.

Heat Capacity and Entropy.

The molecular constants were estimated by J. S. Gordon, Astrostats International, Livingston, New Jersey, private communication, April 25, 1963.

$$\omega_e X_e = 2.27 \text{ cm}^{-1}$$

Heat of Formation

The adopted value is based on $D_0^\circ = 90 \pm 15$ kcal/mol which is calculated from $D_0^\circ/D'(LBX) = 1.01$ and $D'(LBX) = 89$ kcal/mol. The latter value comes from linear Birge-Sponer extrapolation of ground state vibrational constants obtained by Verma (1) from the B'-X system. The ratio $D_0^\circ/D'(LBX) = 1.01$ is calculated from an empirical relationship proposed by Hildenbrand (2): $D_0^\circ/D'(LBX) = 0.365(r_e/r_e^\circ) + 0.448$ and $r_e^\circ = 1.40 \text{ \AA}$ (IP-EA), where IP is the ionization potential of the more electronegative element and EA is the electron affinity of the more electronegative element. A similar calculation using $\omega_e X_e = 2.1 \text{ cm}^{-1}$ obtained from the B-X system (2) would give $D_0^\circ = 98$ kcal/mol. These values for D_0° may be compared with average (per bond) heats of atomization of 101 kcal/mol for SiCl_2 and 94 kcal/mol for SiCl_4 .

Gaydon (3) selected $D_0^\circ = 7612$ kcal/mol on the assumption that $D_0^\circ/D'(LBX) = 0.8$, but Ovcharenko (4) suggested that this was too low by comparison with $D_0^\circ = 117$ kcal/mol obtained from the B' state. The latter value is calculated from $D'(LBX) = 33$ kcal/mol and presumes that $\text{Si}(\text{D})$ is the excited atomic product. The B and C states could also correlate to give values fairly consistent with $D_0^\circ = 117$. This interpretation seems unlikely, however, because it would involve a crossing of the potential curves for the B and B' states. Since the potential curves may be distorted due to the close proximity of the B and B' states, it seems preferable to obtain D_0° from constants for the ground state.

Heat Capacity and Entropy

Electronic levels of the B and C states are taken from the B-X and C-X systems reported by Ovcharenko et al. (5, 6). The A level is that assigned by Sanii (10) from analysis of the A-X system. The D level is that derived by Herzberg (7) from data of Jevons (2), but it is assigned as π as suggested by Verma (1). The B' level is from Verma and is confirmed by the earlier analysis of Ovcharenko (4). All vibrational and rotational constants for the ground state are those obtained by Verma (1) from the B'-X system. Values only slightly different were obtained from the B-X system by Ovcharenko (5, 6). The adopted constants are adjusted to the natural isotopic abundances of Si and Cl.

Heat of Formation

The heat of formation, ΔH_f° , of TiCl (g) is calculated from the dissociation energy, D_0° , which is estimated as 105 kcal/mol. This estimate is obtained from the relation $D(\text{TiCl}) < D_0^\circ(\text{TiCl}) < D_0^\circ(\text{TiCl})$, where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of $\text{TiF}_2(\text{g})$ by Zmbov and Margrave (1).

Extrapolations of the vibrational levels reported by Shenyavskaya (2), Rao (3) and Mace and Packer (4) yield values of the dissociation energy which are very low when considered with respect to bond energy relations.

Heat Capacity and Entropy

The vibrational frequency, ω_e , and anharmonic vibrational term, $\omega_e x_e$, were reported by Shenyavskaya et al. (2). The interatomic distance is estimated from Guggenheimer's relation (5). B_e is calculated from r_e . The ground state term and electronic levels are estimated from the ground state multiplet of $\text{Ti}^2(\text{g})$. q_e is estimated from the Morse potential function.

0	[4]
[5000]	[2]
[15000]	[20]

 $\omega_e x_e = [1.46] \text{ cm}^{-1}$ $\sigma = 1$ $B_e = [0.11105] \text{ cm}^{-1}$ $r_e = [2.26] \text{ Å}$

Heat of Formation

The heat of formation, ΔHf°₂₉₈(WCl, g) = 132.3 kcal/mol, is calculated from the bond dissociation energy, D°₂₉₈(W-Cl) = 100 ± 10 kcal/mol. This estimated D°₂₉₈ is obtained from the average bond dissociation energy for WCl_x(g) + W(g) + xCl(g) where x = 2, 4, 5, 6, using all JANAF values.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in WCl₂(g). This distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental vibrational frequency ω_e (K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 455 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D_0 + 0.5 \omega_e) = 0.0032$. The rotational constant B_e is calculated from the estimated bond distance. The value of σ_e is calculated from the Morse potential function. The moment of inertia is $25.20 \times 10^{-39} \text{ g cm}^2$. The ground state configuration, low lying electronic levels and their quantum weights are assumed to be the same as those estimated for WF(g). See WF(g) table (March 31, 1967) for details.

C/W

Zirconium Monochloride (ZrCl)

(Ideal Gas) GFW = 126.673

ZIRCONIUM MONOCHLORIDE (ZrCl)

(IDEAL GAS)

GFW = 126.673

 $\Delta H_f^\circ = 49.3 \pm 5$ kcal/mol $\Delta H_f^\circ(298.15) = 49.1 \pm 5$ kcal/mol

Ground State Configuration [4f]

 $S^\circ_{298.15} = [60.8 \pm 2]$ gibbs/mol

Heat of Formation

Potter (1) investigated mass spectrometrically the gaseous equilibria among ZrCl, ZrCl₂, ZrCl₃ and ZrCl₄. Ion intensities were measured 2.5 eV above the ionization threshold. Using the reported equilibrium constants for the reaction ZrCl₃(g) + ZrCl(g) = 2 ZrCl₂(g) in the temperature range 1978-2274°K, second and third law analyses give the heats of reaction at 298°K as -10.36 and -12.83 kcal/mol, respectively. The third law drift is 1.4 ± 2.5 eu. Based on the third law $\Delta H_f^\circ(298)$ and $\Delta H_f^\circ(298)$, $g^\circ = -44.5$ kcal/mol (2), and $\Delta H_f^\circ(298)$ (3), we obtain $\Delta H_f^\circ(298)$ (ZrCl, g) = 49.1 kcal/mol which is adopted in the tabulation.

Farber et al. (4) also studied mass spectrometrically the reaction Zr(c) + Cl(g) + ZrCl(g). They reported a second law heat of reaction, $\Delta H^\circ_{298} = 8.7 \pm 1.4$ kcal/mol. Using the equilibrium constants $K = (ZrCl)/(Cl)$ which we calculated from their reported ion intensities of run 3 in the temperature range 1667-1896°K, we obtain $\Delta H_f^\circ(298) = 20.3$ kcal/mol by the third law method. The third law drift is 6.1 ± 2.4 eu. The heat of formation is derived as $\Delta H_f^\circ(298)$ (ZrCl, g) = 49.2 kcal/mol.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in ZrCl₄(g). The bond distance is then used with Guggenheimer's relation (5) for polar molecules to calculate the fundamental vibrational frequency ω_e . The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/(v_e^2 + 0.5 \omega_e) = 0.0025$. The rotational constant B_e is calculated from the estimated bond distance. The value of a_e is calculated from the Morse potential function. The moment of inertia is 22.425×10^{-39} g cm².

The ground state configuration is taken from the ground state multiplet of Zr⁺ reported by Moore (6). The electronic levels and the quantum weights are estimated to be the same as those of ZrF(g).

CHLORINE, DIATOMIC (Cl₂)

MOL. WT. = 70.906

(IDEAL GAS - REFERENCE STATE)

Ground State Configuration 1Σ⁺
S°_{298.15} = 53.29 ± 0.01 cal. deg.⁻¹ mole⁻¹
ΔH°_f 0 = 0
ΔH°_f 298 = 0

Electronic Levels and Multiplicities

State	E cm. ⁻¹	g _i
1Σ ⁺	0	1
3Π ⁺	16,147 ± 500	1
3Π ₁	17,841 ± 500	2
3Π ₂	17,560 ± 500	2

ω_e = 561.1 cm.⁻¹
B_e = 0.2408 cm.⁻¹
ω_ex_e = 4.0 cm.⁻¹
α_e = 0.0017 cm.⁻¹
r_e = 1.986 Å
σ = 2

Heat of Formation.

The heat of formation (ΔH°_f) for Cl₂(g) is zero at all temperatures, by definition.

Heat Capacity and Entropy.

The functions adopted here were calculated by R. L. Potter, J. Chem. Phys. 31, 1100 (1959) using a direct summation over the energy levels not including those of non-bonding states. The functions are for the naturally occurring isotopic composition.

The absorption spectrum of chlorine has been observed by A. Elliott, Proc. Roy. Soc. A 127, 638 (1930); C. F. Goodeve and B. A. Stephens, Trans. Faraday Soc. 32, 151.7 (1936); H. Stammreich, R. Fornaria and Y. Tsuvaris, Spectrochim. Acta, 17, 775 (1961); Y. V. Rao and P. Venkateswarlu, J. Mol. Spectr. 9, 173 (1962); and A. E. Douglas, C. K. Møller and B. P. Stoicheff, Can. J. Phys. 41, 1174 (1963). There is disagreement over the vibrational assignments. The listed ground state spectroscopic constants for the naturally occurring isotopic composition are based upon the abundances given by D. Strominger, J. M. Hollander and G. T. Seaborg, Rev. Mod. Phys. 30, 585 (1958).

The molecular structure of gaseous chlorine was determined by the sector-microphotometer method of electron diffraction by S. Shibata, J. Phys. Chem. 57, 2256 (1953). The value of r_e(Cl-Cl) was found to be 1.986 Å. The other r_e values, 1.983 - 1.989 Å, were reported by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., 1950; M. G. Richards and R. F. Barrow, Proc. Chem. Soc., 297 (1962), and L. S. Bartell and K. Kuchitsu, presented at the International Conference on Magnetism and Crystallography, 1961, quoted by S. Shibata, loc. cit.

σ = [4]

Heat of Formation

Datz (1) studied the molecular association equilibrium in cesium chloride vapors by measuring the temperature dependence of the molecular weight of gaseous CsCl. The molecular weights were determined by measurement of the absolute pressure exerted by a known weight of completely vaporized salt contained in an isothermal fused silica bulb of known volume. The pressure sensing element was a fused silica manometer containing Au(t). Based on the reported results, we derive the equilibrium constants for the reaction Cs₂Cl₂(g) = 2CsCl(g) in the temperature range 1224 - 1418°K. The enthalpy change of this reaction is evaluated by the second and third law method as 39.3 ± 1.1 and 42.9 ± 0.6 kcal/mol, respectively. The drift in the third law value is equivalent to an entropy error of 2.7 ± 0.8 eu. Using the third law ΔH_f° and ΔH_f°₂₉₈ (CsCl, g) = -57.4 kcal/mol, we obtain ΔH_f°₂₉₈ = -157.7 ± 2.5 kcal/mol for Cs₂Cl₂(g), which is adopted.

Schrier (2) determined the vapor pressures of molten cesium chloride at temperatures between 1165 and 1387°K by the boiling point or manometric method. The vapor analysis was performed using the transpiration method. An inert gas, N₂, was passed over the CsCl sample at a given temperature. The salt vapor entrained by the carrier gas was collected, weighed and analyzed. The data obtained were combined with the boiling point measurements to yield the average molecular weight of the vapor. Association into dimer was postulated. The mole fraction in the vapor and the partial pressure of CsCl(g) and Cs₂Cl₂(g) were calculated. The equilibrium constants, 1209 - 1350°K, for dissociation of the Cs₂Cl₂ dimer were derived. Using the reported equilibrium constants, we evaluate the enthalpy change (ΔH_f°₂₉₈) of the reaction Cs₂Cl₂(g) = 2CsCl(g) to be 34.1 ± 2.9 and 43.2 ± 0.9 kcal/mol by the second and third law methods. Based on the third law ΔH_f°₂₉₈ value and ΔH_f°₂₉₈ (CsCl, g) = -57.4 kcal/mol, we obtain ΔH_f°₂₉₈ = -156.0 kcal/mol for Cs₂Cl₂(g), which is in agreement with the adopted value.

Miller and Kusch (3) made an analysis of the velocity distribution of the CsCl molecules which escape through an ideal aperture from an isothermal enclosure. They found that there was no definite evidence that any species other than diatomic molecules were present in the beams in measurable amounts, in other words, the dimerization must be small, e.g. <1.5 per cent. However, according to our calculation the concentration of dimer is 15 - 34 per cent in the temperature range 600 - 900°K, and 33 - 20 per cent at the temperatures 1000 - 1600°K.

Heat Capacity and Entropy

The molecular structure is assumed to be planar, having D_{2h} symmetry. Based on the bond distances of Cs-Cs and Cl-Cl estimated by Berkowitz (4), the Cs-Cl bond distance and Cl-Cs-Cl bond angle are calculated. The vibrational frequencies were calculated by Berkowitz (4), on the basis of the potential function for an ionic model. The three principal moments of inertia are: I_A = 2.105 × 10⁻³⁷, I_B = 6.272 × 10⁻³⁷, and I_C = 2.732 × 10⁻³⁷ g cm².

COPPER DICHLORIDE (CuCl₂)

(CRYSTAL)

MOL. WT. = 134.446

$$\Delta H_f^0 = -49.39 \pm 1.5 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{298.15} = -49.2 \pm 1.5 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 25.833 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_d = [766]^{\circ}\text{K.}$$

Heat of Formation.

S. A. Shchukarev and M. A. Oranskys, Zhur. Obshchei Khim. 24, 1928 (1954) have reported equilibrium constants for the dissociation $\text{CuCl}_2(\text{c}) \rightarrow \text{CuCl}(\text{c}) + 0.5 \text{ Cl}_2(\text{g})$, which are in general agreement with earlier reports by P. Ephraim, Ber. 50, 1089 (1917) and D. I. Tarasenkov, A. I. Origorovich and A. V. Boroslovskys, Collected Works of the Central State Institute for Non-Ferrous Metallurgy, Part 1, 1, 69 (1929). These data were subjected to third law analysis which revealed a significant trend of $13 \pm 0.5 \text{ cal. deg.}^{-1} \text{ mole.}$, indicating that equilibrium conditions were not reached. However an average value of $\Delta H_f^{298} = 16.5 \pm 1.9 \text{ kcal. mole}^{-1}$ yields a heat of formation of $\text{CuCl}_2(\text{c}) = -49.5 \pm 2.5 \text{ kcal. mole}^{-1}$ which is in good agreement with the adopted value taken from Natl. Bureau Std. Circular 500, Washington, 1952.

Heat Capacity and Entropy.

The low temperature heat capacity has been measured from 11-300°K. by J. W. Stout and R. C. Chisholm, J. Chem. Phys. 36, 979 (1962). The integration of this data from $S_{10} = 0.111 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ gave $S_{298} = 25.833 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$. The heat capacity above 298° was obtained by smooth extrapolation of the above data, since the heat capacities of A. N. Krestovnikov and O. A. Karetnikov, Journ. Gen. Chem. (USSR) 5, 955 (1956) were not compatible with the low temperature data.

Decomposition Data.

The temperature of decomposition was estimated from the table for $\text{CuCl}_2(\text{c})$, $\text{CuCl}(\text{l})$ and $\text{Cl}_2(\text{g})$ so that the pressure of Cl_2 is 1 atm.

Phosphoryl Fluoride Dichloride (POCl₂F)
(Ideal Gas) Mol. Wt. = 136.889

PHOSPHORYL FLUORIDE DICHLORIDE (POCl₂F) (IDEAL GAS) MOL. WT. = 136.889

Bond Angle: Cl-P-Cl = 103°

Product of the Moments of Inertia: I_AI_BI_C = 4.70732540 X 10⁻¹¹³ g.³ cm.⁶

Heat of Formation.

The ΔH_f^{298.15} of POCl₂F was estimated to be -179 kcal. mole⁻¹ from the ΔH_f^{298.15} of POCl₃ by assuming bond energies of 120 kcal. for D(P-F) and 80 kcal. for D(P-Cl). The D(P-F) and D(P-Cl) values were taken from Moore, J. Chem. Soc. 422 (1956) Part II.

Essentially the same ΔH_f^{298.15} may be obtained by assuming a ΔH_f^{298.15} = 0 for the following reaction:

Heat Capacity and Entropy.

The molecular constants were determined by L. O. Brockway and J. Y. Beach, J. Am. Chem. Soc. **60**, 1836 (1938) and by Q. Williams, J. Sheridan, and M. Gordy, J. Chem. Phys., **20**, 164 (1952). Brockway and Beach used electron diffraction. Q. Williams et al. measured microwave spectra. Brockway and Beach assumed that the P-P-F and P-P-Cl angles were equal in POCl₂F and POCl₃. An analysis of their data by Q. Williams et al. indicates that the angles in POCl₂F, POCl₃, and POF₃ should be 103° rather than the reported 106° ± 3°. The principal moments of inertia calculated from these parameters were I_A = 2.69184 X 10⁻³⁸, I_B = 3.79516 X 10⁻³⁸, and I_C = 4.60780 X 10⁻³⁸.

The Raman spectra and vibrational frequencies for POCl₂F were reported by M. L. Delwaule and P. Francois, Compt. Rend. **222**, 550 (1946). These frequency assignments are summarized in J. Chim. Phys. **45**, 87 (1949) by M. L. Delwaule and P. Francois.

IRON DICHLORIDE (FeCl₂)
(CRYSTAL)

MOL. WT. = 126.753

$$\Delta H_f^0 = -82.32 \pm 0.12 \text{ kcal. mole}^{-1}$$
$$\Delta H_f^{298.15} = -81.70 \pm 0.12 \text{ kcal. mole}^{-1}$$
$$\Delta H_m^0 = 10.28 \pm 0.05 \text{ kcal. mole}^{-1}$$
$$\Delta H_m^{298.15} = 48.2 \pm 0.7 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^{298.15} = 28.190 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 950^\circ \text{K.}$$

Heat of Formation.

The enthalpy change, $\Delta H_f^{298.15} = -4.05 \pm 0.05 \text{ kcal. mole}^{-1}$, for the reaction $\text{Fe}(\text{cl}) + 2(\text{HCl} \cdot 12.731 \text{ H}_2\text{O}) (l) = \text{FeCl}_2(c) + \text{H}_2\text{O}(l)$ was reported by M. P. Kohler and J. P. Coughlin, *J. Phys. Chem.* **63**, 605 (1959). The enthalpy change, $\Delta H_f^{298.15} = -19.5 \pm 0.2 \text{ kcal. mole}^{-1}$, for the reaction $\text{FeCl}_2(c) + \text{H}_2\text{O}(l) = \text{Fe}^{++}(\text{aq.}) + 2 \text{Cl}^{-}(\text{aq.})$ was then derived. The value of $\Delta H_f^{298.15}(\text{FeCl}_2(c))$ was determined by J. C. M. Li and N. W. Gregory, *J. Am. Chem. Soc.* **74**, 4670 (1952), yielding $\Delta H_f^{298.15} = -81.4 \pm 0.2 \text{ kcal. mole}^{-1}$ which is in agreement with the adopted value reported by M. P. Kohler and J. P. Coughlin. The equilibrium constants for the reaction $\text{FeCl}_2(c) + \text{H}_2\text{O}(l) = \text{Fe}(c) + 2\text{HCl}(g)$ were determined by W. Kangro and E. Petersen, *Z. Anorg. Chem.* **261**, 157 (1950). By use of the second and third law methods the enthalpy change ($\Delta H_f^{298.15}$) of this reaction was evaluated as 37.81 ± 0.68 and $38.24 \text{ kcal. mole}^{-1}$, respectively. Based on the third law value for $\Delta H_f^{298.15}$, the value of $\Delta H_f^{298.15}(\text{FeCl}_2(c))$ was derived to be $-82.37 \text{ kcal. mole}^{-1}$ which is in reasonable agreement with the adopted value.

Heat Capacity and Entropy.

The low temperature ($53.2-295.0^\circ \text{K.}$) heat capacities were determined by K. K. Kelley and O. E. Moore, *J. Am. Chem. Soc.* **65**, 1264 (1943). The high temperature ($670.5-941.0^\circ \text{K.}$) heat capacities were measured by O. E. Moore, *J. Am. Chem. Soc.* **65**, 1700 (1943). The two sets of C_p data were plotted and joined smoothly at 298°K. The C_p values above 941.0°K. were obtained by graphical extrapolation. The C_p values, $60-500^\circ \text{C.}$, were also reported by F. L. Oetting and N. W. Gregory, *J. Phys. Chem.* **65**, 138 (1961) which are in good agreement with those determined by O. E. Moore, loc. cit. $S_{298.15}^{298.15}$ was derived from the smoothed C_p values, using $S_{53.2}^{298.15} = 4.930 \text{ e.u.}$ The $S_{298.15}^{298.15}$ value was determined by E. F. Westrum, Jr. quoted by L. E. Wilson and N. W. Gregory in *J. Phys. Chem.* **62**, 437 (1958). The entropy at 298° is assumed to include the uncoupling energy of Fe^{++} which is calculated to be 3.2 e.u. which corresponds to R in 5.

Melting Data.

T_m and ΔH_m^0 were taken from O. E. Moore, loc. cit.

Heat of Sublimation.

The difference between $\Delta H_f^{298.15}$ for $\text{FeCl}_2(g)$ and $\text{FeCl}_2(c)$ is $\Delta H_s^{298.15}$. The former was obtained by the second and third law analyses on the equilibrium pressure data as described in $\text{FeCl}_2(g)$ table.

$$\Delta H_f^{298.15} = -74.411 \pm 0.13 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{298.15} = 10.28 \pm 0.05 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^{298.15} = 29.83 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^{298.15} = 33.432 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 950^\circ \text{K.}$$

$$T_b = 1347^\circ \text{K.}$$

Heat of Formation.

The value of $\Delta H_f^{298.15}(\text{FeCl}_2, \text{l})$ was obtained from $\Delta H_f^{298.15}(\text{FeCl}_2, \text{c})$ by adding $\Delta H_m^{298.15}$ and the difference between $H_m^{298.15} - H_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity (950-1100°K.) for FeCl₂(l) was reported as 24.42 cal. deg.⁻¹ mole⁻¹ by O. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943). A constant C_p was assumed for all the other temperatures. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and $\Delta H_m^{298.15}$ were taken from G. M. Moore, loc. cit.

Vaporization Data.

The boiling point (T_b) is determined as the temperature at which the free energy change ($\Delta F_b^{298.15}$) for the reaction FeCl₂(l) = FeCl₂(g) approaches zero. The corresponding enthalpy change ($\Delta H_b^{298.15}$) at T_b is the heat of vaporization ($\Delta H_v^{298.15}$).

Rotational Constant: B₀ = [0.05442] cm⁻¹

Heat of Formation

The equilibrium pressures for the reactions: (1) FeCl₂(l) = FeCl₂(g); (2) FeCl₂(c) = FeCl₂(g); and (3) Fe(c) + 2HCl(g) = FeCl₂(g) + H₂(g) were determined by several investigators. Using the reported data, the corresponding enthalpy changes (ΔH_f^o , 298.15) for these reactions were evaluated by both the second and third law methods. Hence the respective ΔH_f^o , 298.15 values for FeCl₂(g) were derived, based on the third law values for ΔH_f^o , 298.15. The results obtained are presented as follows.

Investigator	Reaction	Temperature, °K.	Second Law Value	Third Law Value	ΔH_f^o , 298.15 kcal. mole ⁻¹
Beuman ¹	(1)	980.2-1167.2	37.07 ± 0.61	36.42	298.15 ± 0.30
Schoonmaker and Porten ²	(2)	621.0-701.0	45.61 ± 0.10	46.14	-35.45 ± 0.20
H. Schäfer, et al. ³	(1)	981.0-1107.0	38.95 ± 0.10	37.77	-36.10 ± 0.30
Schäfer and Krehl ⁴	(1)	980.7-1108.7	40.56 ± 1.45	37.78	-39.11 ± 0.50
C. G. Meier ⁵	(1)	972.1-1268.0	38.68 ± 0.18	37.95	-35.92 ± 0.30
Schäfer and Krehl ⁴	(3)	1205.2-1373.2	4.10 ± 0.13	8.01	-36.13 ± 0.50

² R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. **29**, 116 (1956).

³ H. Schäfer, L. Bayer, G. Breil, K. Etzel and K. Krehl, Z. anorg. allgem. Chem. **278**, 300 (1955).

⁴ H. Schäfer and K. Krehl, Z. anorg. allgem. Chem. **266**, 35 (1952).

The value of ΔH_f^o , 298.15 for FeCl₂(g) adopted is -35.5 ± 2.0 kcal. mole⁻¹.

Heat Capacity and Entropy

The molecular structure, bond distance and angle, and two vibrational frequencies (ν_1 and ν_2) were obtained from L. Brewer, G. R. Sonzogni and E. Brackett, Chem. Rev. **63**, 111 (1963). The electronic levels and quantum weights were estimated by comparison with the electronic levels in Fe²⁺(g) reported by C. E. Moore, "Atomic Energy Levels", Circular of the National Bureau of Standards 467, Vol. II, 1952, using the reasoning suggested by J. T. Hougen, O. E. Leroi and T. C. James, J. Chem. Phys. **34**, 1970 (1961). The total 2S for the quantum weight was obtained from the ground multiplet of Fe²⁺ and was split arbitrarily. The bending frequency (ν_3) was derived such that the calculated free energy functions are consistent with the experimental equilibrium data. In other words, the free energy functions were adjusted by choosing a proper value for ν_3 in order to make the second and third law values of ΔH_f^o for the reaction in reasonable agreement. The moment of inertia (I) is 5.1426×10^{-38} g. cm².

 $\Delta H_f^{298.15} = -55.000 \pm 1.0$ kcal. mole⁻¹ $S_{298.15}^{298.15} = [34.535] \pm 1.5$ cal. deg.⁻¹ mole⁻¹ $T_m = 550^\circ K$ $\Delta H_m = 4.64 \pm 0.05$ kcal. mole⁻¹

Heat of Formation. Taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," (1952).

Heat Capacity and Entropy. C_p was determined from the heat content data of L. E. Topol and L. D. Ransom, J. Phys. Chem. 54, 1359 (1950) and R. Ewald, Ann. d. Physik u. Chem. (4) 44, 1213 (1914).

Above 550° the curve was smoothly extrapolated. The entropy was estimated by adjusting the value to give the best fit of the melting, sublimation, and vaporization data.

Melting. T_m was taken from National Bureau of Standards Circular 500 (loc. cit.) ΔH_m was given by L. E. Topol and L. D. Ransom (loc. cit.).

MERCURY DICHLORIDE (HgCl₂) (liquid)

Mol. Wt. = 271.524
 ΔH_f° 298.15 = -51.404 ± 1.0 kcal. mole⁻¹
 $S_{298.15}^\circ$ = [40.721] ± 1.5 cal. deg.⁻¹ mole⁻¹
 T_m = 550°K
 ΔH_m = 4.64 ± 0.05 kcal. mole⁻¹
 T_b = 577°K
 ΔH_v = 14.079 ± 0.25 kcal. mole⁻¹

Heat of Formation. Calculated from $\Delta H_f^\circ(c)$.

Heat Capacity and Entropy. The heat capacity was estimated to conform with the bromide and iodide, the value given by L. E. Topol and L. D. Ransom, J. Phys. Chem. 64, 1339 (1960) was discounted. A glass type transition was assumed at 367°K below which the heat capacity was equal to that of the crystal. The entropy was obtained from $S^\circ(c)$, the entropy of fusion and the estimated heat capacity.

Fusion and Vaporization. T_m and T_b were taken from National Bureau of Standards (U.S.) Circular 500 (1952). ΔH_m was given by L. E. Topol and L. D. Ransom, J. Phys. Chem. 64, 1339 (1960) and ΔH_v was obtained from the data of E. B. R. Frideaux, J. Chem. Soc. (London) 97, 2033 (1910) and F. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

 70 {
 413 {

Hg-Cl distance = 2.31 Å

Moment of Inertia = 62.622 X 10⁻³⁹ g. cm.² σ = 2

Heat of Formation. The heat of formation of the crystal as given in National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952 was combined with the 3rd law heat of sublimation at 298°K from the data of K. Nira and Z. Shabetz, J. Fac. Sci. Hokkaido Imp. Univ. Ser. III, 2, 193 (1958); R. Ruf and W. D. Treadwell, Helv. Chim. Acta 37, 1941 (1954) and P. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

Heat Capacity and Entropy. The vibrational constants were given by W. Klemperer and L. Lindeman, J. Chem. Phys. 25, 397 (1956). The bond length is a weighted average of the values given by H. Braune and S. Knoke Naturwiss. 21, 349 (1933); A. H. Gregg, G. C. Hampson, G. I. Jenkins, P. L. F. Jones and L. E. Sutton Trans. Farad. Soc. 33, 852, 1937; L. R. Maxwell and V. M. Monley Phys. Rev. 57, 21 (1940) and P. A. Akshat, V. P. Spiridonov and A. N. Knouchenkov, Zhur. Fiz. Khim. 33, 20 (1959).

MERCURY MONOCHLORIDE, DIMERIC (Hg_2Cl_2) (CRYSTAL)

MOL. WT. = 472.134

$\Delta H_f^\circ 298.15 = -63.319 \pm 0.05 \text{ kcal mole}^{-1}$

$S^\circ_{298.15} = 46.017 \text{ cal deg}^{-1} \text{ mole}^{-1}$

$T_{\text{sub.}} = 655^\circ\text{K (decomp.)}$

Heat of Formation

Based on the average free energy of formation, $-50.315 \text{ kcal mole}^{-1}$, as measured by R. H. Gerke, J. Am. Chem. Soc. 44, 1684 (1922) and G. J. Hills and D. J. G. Ives, J. Chem. Soc. (London) 318, (1951), and the entropy of formation.

Heat Capacity

The data of F. Pollitzer, Zeits. f. Electrochemie 19, 513 (1913), from 22-199°K was treated by K. K. Kelley, U. S. Bureau of Mines Bulletin 592 (1960). The heat capacities listed by Kelley were raised by 0.05 to match the entropy data of Gerke (loc. cit.). Data above room temperature were obtained by smooth extrapolation.

Entropy

A mean value of the entropy of formation of -46.614 e.u. was adopted from the cell measurements of R. H. Gerke (loc. cit.).

Sublimation

The vapor pressure over mercurous chloride reaches 1 atmosphere at 655°K according to A. Smith and A. W. C. Menzies, J. Am. Chem. Soc. 32, 1541 (1910). At this point the vapor is dissociated into Hg(g) and $\text{HgCl}_2\text{(g)}$.

Bond Distance: Cl-K = [2.352] Å

Bond Angle: Cl-K-Cl = [100.8°]

Product of the Moments of Inertia: I_AI_BI_C = [2.875 X 10⁻¹¹²] g.³ cm.⁶

σ = 4

Heat of Formation.

The heat of formation is calculated from that of KCl(g) using ΔH_f⁰ 298 = 45.0 kcal./mole for K₂Cl₂(g) - 2KCl(g) as selected from data analyses summarized below. The three experimental techniques include PVT measurements (source 1), combination of total vapor pressure and transpiration data (sources 2,3,4), and mass spectrometric studies of the variation of ion intensities with temperature (source 5). The results are reasonably consistent, considering the uncertainties inherent in the problem.

The resulting tables were tested by comparison with other data. Calculated total vapor pressures are in satisfactory agreement with the observed values over the range 820-1500°K.; however, near the boiling point they are lower by 6-18 percent [see KCl(g)]. Knudsen effusion data and transpiration data over KCl(c) have been reviewed by A. C. P. Pugh and R. F. Barron, *Trans. Faraday Soc.* 53, 671 (1958). These data suggest negligible dimer formation when combined with the total vapor pressures of V. Dietz, *J. Chem. Phys.* 4, 575 (1936). Calculated dimer formation (22 mole percent at 900°K.) agrees with the latter combination but calculated total pressures agree with those of Pugh & Barron. Velocity distribution studies of R. C. Miller and P. Kusch, *J. Chem. Phys.* 21, 981 (1957); 25, 860 (1956) suggest about 10 mole percent of dimer at 900°K. Thus, while minor inconsistencies do exist, it is not apparent that they exceed the combined experimental errors.

Heat Capacity and Entropy.

The structure and vibrational frequencies are those calculated from an ionic model by J. Berkowitz, *J. Chem. Phys.* 32, 1519 (1960); 22, 1386 (1958). The sixth fundamental was arbitrarily lowered from 206 to 100 cm.⁻¹ since the resulting entropy increase (1.4 eu at 1300°K.) improved the overall agreement with the equilibrium data. Based on electron diffraction studies of the monomer-dimer vapor, P. A. Aklehin and N. O. Rambidi, *Zhur. Neorg. Khim.* 3, 718 (1959) have derived the bond distances and angle to be 2.81 Å and 98°. Interpretation of the diffraction data, however, is complicated by the presence of only about 30 mole percent of dimer at the temperature of measurement. Adoption of this dimer structure would reduce the entropy by 0.23 eu. Principal moments of inertia for the Berkowitz structure are I_A = 45.31 X 10⁻³⁹, I_B = 60.13 X 10⁻³⁹, and I_C = 105.45 X 10⁻³⁹ g. cm.²

Bond Lengths and Angles
 Li-Cl distance = 2.62 Å
 Li-Li distance = 2.23 Å
 Cl-Li-Cl angle = 108 ± 4° $\sigma = 4$

Moment of Inertia I_AI_BI_C = 6418 × 10⁻¹¹ g.² cm.²

Heat of Formation. A heat of sublimation at 298° of 52.1 kcal. mole⁻¹ was chosen to fit the vapor pressure data and relative concentrations of monomer, dimer and trimer as described in the table for LiCl(g). This value is in reasonable agreement with the value of 53.5 kcal. mole⁻¹ from a 3rd law analysis of the vapor pressure data of An. N. Nesmeyanov and L. A. Sazonov, Zhur. Neorg. Khim. 4, 231 (1960) and the relative concentrations of monomer, dimer, and trimer from the work of R. C. Miller and P. Kuech, J. Chem. Phys. 25, 860 (1956). Also a value of 54.1 kcal. mole⁻¹ was found by T. A. Milne and H. M. Klein, J. Chem. Phys. 33, 1628 (1960), from mass spectrometer studies.

Heat Capacity and Entropy. W. Klemperer and W. G. Norris, J. Chem. Phys. 34, 1071 (1961), observed two bands in the infra-red spectrum and made tentative assignments. The remaining four frequencies were calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960), from a reasonable model. The bond lengths and angles were determined from the electron diffraction experiments of S. H. Bauer, T. Ino and R. F. Porter, J. Chem. Phys. 33, 685 (1960).

MOL. WT. = 95.218

$$\Delta H_f^0 = -153.25 \pm 0.11 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{298.15} = -153.35 \pm 0.11 \text{ kcal. mole}^{-1}$$

$$\Delta H_m = 10.30 \pm 0.05 \text{ kcal. mole}^{-1}$$

$$\Delta H_g^{298.15} = 57.5 \pm 1.5 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 21.422 \text{ cal. deg}^{-1} \text{ mole}^{-1}$$

$$T_m = 987^\circ \text{K.}$$

Heat of Formation.

The adopted $\Delta H_f^{298.15} = -153.35 \pm 0.11 \text{ kcal. mole}^{-1}$ is from heat of solution measurements reported by C. H. Shomate and E. H. Huffman, J. Am. Chem. Soc. 65, 1625 (1943). Shomate and Huffman's heat of solution of Mg in 1 M HCl ($\Delta H = -111.322 \pm 0.041 \text{ kcal. mole}^{-1}$) has been substantiated for calibration purposes by S. R. Dunn and B. B. Cunningham, J. Am. Chem. Soc., 79, 1563 (1957) ($\Delta H = -111.3 \text{ kcal. mole}^{-1}$) and by E. F. Westrum Jr. and L. Eyring, J. Am. Chem. Soc., 74, 2045 (1952) ($\Delta H = -111.27 \text{ kcal. mole}^{-1}$). Auxiliary heat of dilution and heat of formation data for HCl were taken from V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes", NBS-RS-2, Nat'l. Bur. Stds., April 1965 and from D. D. Wagman et al., N.B.S. Technical Note 270-1, Oct. 1965.

Heat Capacity and Entropy.

High temperature heat content data by O. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943) were joined by Shomate correlation with low temperature heat capacity data reported by K. K. Kelley and O. E. Moore, J. Am. Chem. Soc. 65, 1264 (1943). $C_p(c)$ above T_m is a linear extrapolation from 700°K. $S_{298.15}^0$ is derived from the low temperature data and is based on $S_{53.6}^0 = 2.006 \text{ cal. deg}^{-1} \text{ mole}^{-1}$.

Melting Data.

$\Delta H_m = 10.30 \pm 0.05 \text{ kcal. mole}^{-1}$ is taken from heat content measurements of Moore loc. cit. $T_m = 987^\circ \text{K.}$ is from National Bureau of Standards Circular 500, 1952.

Sublimation Data.

The value of $\Delta H_g^{298.15}$ was derived by 2nd and 3rd law analyses of vapor pressure data. See the MgCl₂(g) table for details.

Dec. 31, 1960; Dec. 31, 1965

MAGNESIUM DICHLORIDE (MgCl₂)

(LIQUID)

MOL. WT. = 95.218

Cl₂Mg

S_{298.15} = 30.949 cal. deg.⁻¹ mole⁻¹
 $\Delta H_f^{298.15} = -143.779$ kcal. mole⁻¹
 $\Delta H_m^{298.15} = 10.30 \pm 0.05$ kcal. mole⁻¹
 $\Delta H_v^{298.15} = [37.34]$ kcal. mole⁻¹
 $T_m = 987^\circ\text{K.}$
 $T_b = [1710]^\circ\text{K.}$

Heat of Formation.

$\Delta H_f^{298.15}(l)$ was calculated from $\Delta H_f^{298.15}(c)$ by adding $\Delta H_m^{298.15}$ and the difference between $H_m^{298.15}$ and $H_l^{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A constant $C_p(l) = 22.0$ cal. deg.⁻¹ mole⁻¹ over the temperature range 1006-1428°K. is from the high temperature heat content data of G. E. Moore, J. Am. Chem. Soc. **65**, 1700 (1943). This constant value was assumed to hold from an assumed glass transition of 660°K. to 3000°K. $C_p(l)$ below 660°K. is taken to be that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

See MgCl₂(c) table for details.

Vaporization Data.

T_b is calculated as the temperature at which the free energy change of the reaction $\text{MgCl}_2(l) = \text{MgCl}_2(g)$ approaches zero. The difference between $\Delta H_f^{298.15}$ for $\text{MgCl}_2(l)$ and $\text{MgCl}_2(g)$ at T_b is $\Delta H_v^{298.15}$.

Heat of Formation

Analysis of vapor pressure data on MgCl₂ is clouded by conflicting evidence for the amount of dimer in the vapor. Berkowitz and Marquart (1) by mass spectrometer studies found about 21 dimer at 820°K and derived ΔH_D = -39.2 kcal/mol and ΔS_D = -29.9 gibbs/mol. Schriber and Clark (2) from gas transpiration data calculated about 30% dimer in the saturated vapor at 1100°K, with ΔH_D = -32.0 kcal/mol and ΔS_D = -18.8 gibbs/mol. Thermodynamic functions for the gaseous monomer adopted here are clearly not compatible with large amounts of dimer and it is assumed for the present that the mass spectrometer results are correct.

Several vapor pressure studies have been published and third law analyses are given below. Berkowitz and Marquart (1) gave a single point while the remaining publications gave only equations but not individual points. Total pressures calculated from the equations were corrected for dimer.

Source	Method	Temperature Range (°K)	ΔH _f ⁰ (kcal/mol)
Berkowitz and Marquart (1)	Mass spectrometer	920	68.10
Schriber and Clark (2)	Boiling Point	1208-1413	59.55-59.68
Hildenbrand et al. (3)	Torsion-effusion	802-985	59.55-59.19
Hildenbrand et al. (4)	Torsion-effusion	800-970	58.53-59.38
Fischer et al. (5)	"Ball" method (total vapor pressures)	1138-1435	59.30-59.56

The selected value for ΔH_f⁰₂₉₈ is 59.55 kcal/mol which is combined with ΔH_f⁰₂₉₈ of the crystal to give ΔH_f⁰₂₉₈(s) = -83.80 kcal/mol.

Heat Capacity and Entropy

White, Mann, and co-workers (6) by matrix infrared spectroscopy determined the molecule to be linear with the asymmetric stretching frequency at 590 cm⁻¹ and the doubly degenerate bending frequency at 88 cm⁻¹. The symmetric stretching frequency was estimated as 273 cm⁻¹. The asymmetric stretching was observed by Buchler and Klemperer (7) at 597 cm⁻¹ and by Randall et al. (8) at 588 cm⁻¹, both by infrared spectroscopy of the vapor at high temperature. Electric deflection experiments by Klemperer and co-workers as summarized by Hayes (9) and the electron diffraction data of Akishin and Spiridonov (10) agree with the linear structure within their error limits of about 20°. The Mg-Cl bond length was determined as 2.18 Å by Akishin and Spiridonov (10).

O-Mo-O plane perpendicular to Cl-Mo-Cl plane
Product of Moments of Inertia: I_AI_BI_C = 1.0986 x 10⁻¹¹² g³ cm⁶

Heat of Formation

Graham and Hepler (1) determined calorimetrically ΔH⁰ = -65.3 ± 0.5 kcal/mol for the reaction:
MoO₂Cl₂(c) + 4 NaOH(∞ H₂O) + 2 NaCl(∞ H₂O) + 2 H₂O(l).
Combining this result with the following heat of formation data: ΔH⁰(Na₂MoO₄, ∞ H₂O) = -353.4 ± 0.4 kcal/mol (2);
ΔH⁰(NaCl, ∞ H₂O) = -97.33 ± 0.09 kcal/mol (3); ΔH⁰(NaOH, ∞ H₂O) = -112.46 ± 0.1 kcal/mol (5); ΔH⁰(H₂O, l) = -68.315 kcal/mol (6); we derive ΔH⁰(MoO₂Cl₂, c) = -169.6 ± 1.0 kcal/mol.
Shchukarev et al. (7) measured the heats of solution of MoO₃(c), MoO₂Cl₂(c) and NaCl(c) in NaOH(aq) and derived ΔH⁰ = -45.56 ± 0.5 kcal/mol for the reaction MoO₂Cl₂(c) + 2 NaOH-77 H₂O + MoO₃(c) + 2 NaCl(c) + H₂O(l). Using JANAF auxiliary data (8) we obtain ΔH⁰(MoO₂Cl₂, c) = -172.86 ± 1.0 kcal/mol.
The two investigations differ only in the heat of solution of MoO₂Cl₂(c), both samples were better than 99.9% pure, and multiple determinations on two different samples were employed in each case. We adopt an average of the two values, -171.2 ± 1.7 kcal/mol for ΔH⁰(MoO₂Cl₂, c). Shchukarev et al. (10) reported an equation for the vapor pressure of the solid from which we have calculated a 2nd law ΔH⁰₂₉₈ = 19.9 kcal/mol with an estimated uncertainty of ± 2 kcal/mol, a ΔCp correction of -4.1 gibbs/mol was used (11). Thus, our adopted value is ΔH⁰₂₉₈(MoO₂Cl₂, g) = -151.3 ± 3.5 kcal/mol.

Shchukarev et al. (8) report equilibrium constants for the reaction MoO₂Cl₂(g) + 0.5 O₂(g) ± MoO₃(c) + Cl₂(g). Shchukarev et al. (10) and Hultgren and Brewer (12) reported equilibrium data for the reaction MoO₃(c) + 2 HCl(g) ± MoO₂Cl₂(g) + H₂O(g). Second and third law analyses of these equilibrium data give the following results:

Investigator	No. of Points	ΔH ₂₉₈ ⁰ , kcal/mol	2nd law	3rd law	Drift, gibbs/mol	kcal/mol
Shchukarev et al. (8)	7		-15.6	-30.11 ± 2.0	-15.0	148.0 ± 3.0
Shchukarev et al. (10)	Equation		12.1	13.8 ± 1.0	2.95	150.6 ± 1.2
Hultgren and Brewer (12)	Set I	5	27.2	15.2 ± 1.7	-21.37	149.2 ± 2.0
	Set II	5	26.5	15.4 ± 3.2	-21.75	149.4 ± 3.5

*Third law values
These equilibrium data are in agreement with the adopted heat of formation but are suspect because of the significant drifts and because the range of validity of the equation (10) is estimated.

Heat Capacity and Entropy

The molecular structural data are from the compilation of Sutton (13). Infrared data (14, 15, 16) for vapor phase MoO₂Cl₂ have indicated that the molecule possesses a distorted tetrahedral structure by reason of the similarity of its spectra to that of CrO₂Cl₂. Individual moments of inertia are I_A = 53.397 x 10⁻³⁹, I_B = 63.898 x 10⁻³⁹, and I_C = 32.200 x 10⁻³⁹ g cm². The vibrational frequencies 972, 996, 437, and 437 have been observed in the infrared vapor phase spectra of MoO₂Cl₂ by Baracough and Stals (14). These frequencies were assigned to the symmetric and asymmetric Mo-O and Mo-Cl stretches, respectively. Similar infrared data for these four frequencies have been reported by Iorns and Stafford (15) and Ward and Stafford (16). The rest of the frequencies are from the infrared and Raman studies of crystalline MoO₂Cl₂ by Adams and Churchill (17). Assignments are made by comparison with data reported for CrO₂Cl₂(s) by Miller et al. (18).

Heat of Formation.

An analysis is given below of the more extensive measurements relating to the dimer dissociation, (NaCl)₂(g) → 2NaCl(g). The mass spectrometric studies suggest that higher polymeric species may be neglected. Velocity distribution analyses are consistent with this procedure. When reduced to 298.15°K, the observed heats of dissociation of the dimer show a range of more than 7 kcal., reflecting the considerable uncertainty involved in such measurements. A value of ΔH_f²⁹⁸ = 48.6 kcal. was selected for the dissociation; combining this with ΔH_f²⁹⁸ = 54.9 kcal. mole⁻¹ for sublimation to the monomer leads to ΔH_f²⁹⁸ = 61.2 kcal. mole⁻¹ for sublimation to the dimer.

Heat Capacity and Entropy.

The structure and vibrational frequencies are those calculated from an ionic model by J. Berkowitz, J. Chem. Phys. **32**, 1519 (1960), **29**, 1386 (1958). Electron diffraction studies by Akishin and Rabinovich, Z. Physik. Chem. (Leipzig) **213**, 111 (1960) gave a similar bond angle (108°) and a slightly shorter bond distance (2.50 Å); however, interpretation of the diffraction pattern was complicated by uncertainty in the monomer-dimer ratio for the vapor. Principal moments of inertia for the Berkowitz structure are I_A = 18.01 X 10⁻³⁹, I_B = 53.31 X 10⁻³⁹ and I_C = 71.32 X 10⁻³⁹ g. cm.².

Heat of Formation.

V. A. Kustodins, K. P. Mishchenko and I. E. Flis, Zh. Prikl. Khim. 35, 1374 (1962) (Source 1) derived the heat of formation of Cl_2O dissolved in CCl_4 from solution calorimetry at 278, 283, 298 and 308°K. The heat of formation in CCl_4 was interpolated to 285°K. D. M. Yost and R. C. Felt, J. Am. Chem. Soc. 56, 68 (1934) (Source 2) measured the partial vapor pressures of Cl_2O above its CCl_4 solution at 273 and 298°K which yield the heat of solution -6.59 kcal. mole⁻¹ at 285°K. The $\Delta H_f^\circ 298.15 = 21.0 \text{ kcal. mole}^{-1}$ was calculated from these two values. J. I. Wallace and C. P. Goodeve, Trans. Faraday Soc. 27, 648 (1931) (Source 3) obtained the heat of explosion of $\text{Cl}_2\text{O(g)}$; their data give $\Delta H_f^\circ 298.15 \text{ Cl}_2\text{O(g)} = 21.4 \text{ kcal. mole}^{-1}$ which is in very good agreement with the above. Also F. Günther and K. Wekua, Z. Physik Chem. 154, 183 (1931) (Source 4) measured the heat of explosion; their data give $\Delta H_f^\circ 298.15 \text{ Cl}_2\text{O(g)} = 24.7 \text{ kcal. mole}^{-1}$.

The vibrational frequencies were obtained from M. M. Rochkind and G. C. Pimentel, J. Chem. Phys. 42, 1361 (1965). The infrared spectrum of $\text{Cl}_2\text{O(g)}$ has been investigated previously beginning with the work of C. R. Bailey and A. B. Casate, Proc. Roy. Soc. (London) A142, 132 (1933). K. Hedberg, J. Chem. Phys. 19, 508 (1951) proposed stretching frequencies at 686 cm^{-1} (ν_1) and 989 cm^{-1} (ν_2) but left the bending frequency unknown. Previous evidence concerning the bending mode (ν_2) was shown by Hedberg (loc. cit.) to be spurious. Rochkind and Pimentel (loc. cit.) present infrared studies of Cl_2O gas and condensed phases which reveal the bending frequency and require reassignment of the stretching fundamentals. The bond distance and bond angle were obtained from J. D. Dunitz and K. Hedberg, J. Am. Chem. Soc. 72, 3108 (1950).

The three principal moments of inertia are: $I_A = 2.022 \times 10^{-39}$, $I_B = 2.30808 \times 10^{-39}$, and $I_C = 2.51028 \times 10^{-38} \text{ g. cm.}^2$

*G. B. B. M. Sutherland and W. B. Penny, Proc. Roy. Soc. (London) A159, 678 (1936).

Heat Capacity and Entropy.

The vibrational frequencies were obtained from M. M. Rochkind and G. C. Pimentel, J. Chem. Phys. 42, 1361 (1965). The infrared spectrum of $\text{Cl}_2\text{O(g)}$ has been investigated previously beginning with the work of C. R. Bailey and A. B. Casate, Proc. Roy. Soc. (London) A142, 132 (1933). K. Hedberg, J. Rochkind and Pimentel (loc. cit.) present infrared studies of Cl_2O gas and condensed phases which reveal the bending frequency and require reassignment of the stretching fundamentals. The bond distance and bond angle were obtained from J. D. Dunitz and K. Hedberg, J. Am. Chem. Soc. 72, 3108 (1950).

The three principal moments of inertia are: $I_A = 2.022 \times 10^{-39}$, $I_B = 2.30808 \times 10^{-39}$, and $I_C = 2.51028 \times 10^{-38} \text{ g. cm.}^2$

*G. B. B. M. Sutherland and W. B. Penny, Proc. Roy. Soc. (London) A159, 678 (1936).

Heat Capacity and Entropy.

The vibrational frequencies were obtained from M. M. Rochkind and G. C. Pimentel, J. Chem. Phys. 42, 1361 (1965). The infrared spectrum of $\text{Cl}_2\text{O(g)}$ has been investigated previously beginning with the work of C. R. Bailey and A. B. Casate, Proc. Roy. Soc. (London) A142, 132 (1933). K. Hedberg, J. Chem. Phys. 19, 508 (1951) proposed stretching frequencies at 686 cm^{-1} (ν_1) and 989 cm^{-1} (ν_2) but left the bending frequency unknown. Previous evidence concerning the bending mode (ν_2) was shown by Hedberg (loc. cit.) to be spurious. Rochkind and Pimentel (loc. cit.) present infrared studies of Cl_2O gas and condensed phases which reveal the bending frequency and require reassignment of the stretching fundamentals. The bond distance and bond angle were obtained from J. D. Dunitz and K. Hedberg, J. Am. Chem. Soc. 72, 3108 (1950).

Cl₂O₇

TITANIUM OXIDE DICHLORIDE (TiOCl₂) (IDEAL GAS) MOL. WT. = 134.814

Point Group [C_{2v}]
ΔH°_f 0 = [-130.0] kcal. mole⁻¹
ΔH°_f 298.15 = [-130.4] kcal. mole⁻¹
S°_{298.15} = [76.697] cal. deg.⁻¹ mole⁻¹
Ground State Quantum Weight = [1]

Vibrotional Frequencies and Degeneracies

ω, cm. ⁻¹	ω, cm. ⁻¹
[455] (1)	[250] (1)
[849] (1)	[250] (1)
[120] (1)	[180] (1)

Bond Distances: O-Ti = [1.82] Å Ti-Cl = [2.20] Å

Bond Angles: O-Ti-Cl = [120°] ε = 2

Product of Moments of Inertia: I_AI_BI_C = [4.628 X 10⁻¹¹³] g.³ cm.⁶

Heat of Formation.

ΔH°_f 0 was estimated as -130 kcal. mole⁻¹ by J. S. Gordon, Astrocyeteme, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. ΔH°_f 298.15 was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. Principal moments were: I_A = 42.72 X 10⁻³⁹ g. cm.², I_B = 17.88 X 10⁻³⁹ g. cm.², and I_C = 60.60 X 10⁻³⁹ g. cm.²

TUNGSTEN DIOXYCHLORIDE (WO_2Cl_2)

(CRYSTAL)

OPW = 286.7548

ΔH_f° = Unknown

$\Delta H_f^\circ_{298.15} = -186.5 \pm 1.4 \text{ kcal/mol}$

$S^\circ_{298.15} = [48.0] \text{ gibbs/mol}$

Td = 642°K

Heat of Formation.

S. A. Shchukarev, I. V. Vasil'kova and G. I. Novikov¹ measured calorimetrically the heats of reaction (1) and (2) at 298°K as -67.3 ± 0.2 and $-13.6 \pm 0.11 \text{ kcal/mol}$, respectively. The reactions are given as follows:

(1) $\text{WO}_2\text{Cl}_2(\text{c}) + 4 \text{ NaOH}(16.3\text{H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(80,000 \text{ H}_2\text{O}) + 2 \text{ NaCl}(40,000 \text{ H}_2\text{O}) + 2 \text{ H}_2\text{O}(1)$

(2) $\text{H}_2\text{WO}_4(\text{c}) + 2 \text{ NaOH}(16.3 \text{ H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(20,000 \text{ H}_2\text{O}) + 2 \text{ H}_2\text{O}(1)$.

Based on these data and the heats of dilution for $\text{NaOH}(\text{aq})^2$ and $\text{Na}_2\text{WO}_4(\text{aq})^3$, we obtain $\Delta H_f^\circ_{298} = -53.77 \pm 1.0 \text{ kcal/mol}$ for $\text{WO}_2\text{Cl}_2(\text{c}) + 2 \text{ OH}^-(\infty \text{ H}_2\text{O}) \rightarrow \text{H}_2\text{WO}_4(\text{c}) + 2 \text{ Cl}^-(\infty \text{ H}_2\text{O})$. This leads to $\Delta H_f^\circ_{298}(\text{WO}_2\text{Cl}_2, \text{c}) = -166.5 \text{ kcal/mol}$ using $\Delta H_f^\circ_{298}(\text{H}_2\text{WO}_4, \text{c}) = -270.5 \pm 0.4 \text{ kcal/mol}$ ⁵.

Heat Capacity and Entropy.

$CP_{300} = 25.0 \text{ gibbs/mol}$ is estimated using Kopp's rule. Heat capacities at higher temperature are estimated from those of $\text{WO}_2(\text{c})$, $\text{WO}_3(\text{c})$, $\text{WOCl}_6(\text{c})$. The entropy, $S^\circ_{298} = 48.0 \text{ eu}$, is calculated from $\Delta S^\circ_{298.6} = 32.27 \pm 1.3 \text{ eu}$ for $\text{WO}_2\text{Cl}_2(\text{c}) \rightarrow \text{WO}_2\text{Cl}_2(\text{g})$. The value of $\Delta S^\circ_{298.6}$ is obtained from the second law analysis of the vapor pressure data given by S. A. Shchukarev and A. V. Suvorov⁴.

Temperature of Decomposition.

Shchukarev and Suvorov⁴ found that $\text{WO}_2\text{Cl}_2(\text{c})$ does not melt but decomposes. The saturated vapor over $\text{WO}_2\text{Cl}_2(\text{c})$ consists mainly of $\text{WOCl}_4(\text{g})$ which will disproportionate to form $\text{WO}_2\text{Cl}_2(\text{g})$ and $\text{WOCl}_6(\text{g})$. The estimated Td is derived by interpolation to one atmosphere in the total pressure of $\text{WOCl}_4(\text{g})$, $\text{WO}_2\text{Cl}_2(\text{g})$ reported by Shchukarev and Suvorov⁴.

TUNGSTEN DIOXYDICHLORIDE (WO₂Cl₂)

(IDEAL GAS)

OPW = 286.7548

Point Group [C_{2v}]

$$\Delta H_f^o = -159.7 \pm 8 \text{ kcal/mol}$$

$$\Delta H_f^o = -160.5 \pm 6 \text{ kcal/mol}$$

$$S_{298,15}^o = [84.6] \text{ gibbs/mol}$$

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω_e, cm^{-1}	ω_e, cm^{-1}	ω_e, cm^{-1}
984 (1)	(400) (1)	(150) (1)
972 (1)	(300) (1)	(100) (1)
[400] (1)	(300) (1)	(100) (1)

Bond Distance: W-Cl = [2.26] Å

Bond Angle: Cl-W-Cl = [113°]

Product of the Moments of Inertia: $I_A I_B I_C = [1.165 \times 10^{-112}] \text{ g}^3 \text{ cm}^6$

W-O = [1.81] Å

O-W-O = [109.47°]

O-W-Cl = [90°]

O = [2]

Heat of Formation.

The adopted heat of formation, $\Delta H_f^o(\text{WO}_2\text{Cl}_2, g) = -160.5 \text{ kcal/mol}$, is obtained from $\Delta H_f^o(\text{WO}_2\text{Cl}_2, g) = -160.5 \text{ kcal/mol}$ for $\text{WO}_2\text{Cl}_2(c) \rightarrow \text{WO}_2\text{Cl}_2(g)$. The latter is calculated by the third law method from the partial pressures of $\text{WO}_2\text{Cl}_2(g)$ given by S. A. Shekharov and A. V. Suvorov.⁶ Second law analysis gives $\Delta H_f^o(\text{WO}_2\text{Cl}_2, g) = -160.5 \text{ kcal/mol}$ for $\text{WO}_2\text{Cl}_2(c) \rightarrow \text{WO}_2\text{Cl}_2(g)$. These reported partial vapor pressures of $\text{WO}_2\text{Cl}_2(g)$ were derived by the optical tonometric method from total pressures over $\text{WO}_2\text{Cl}_2(c)$ considering the species $\text{WOCl}_4(g)$, $\text{WO}_2\text{Cl}_2(g)$ and $\text{WCl}_6(g)$. Since the decomposition of $\text{WO}_2\text{Cl}_2(c)$ was very complicated, we tentatively assign 6 kcal/mol uncertainty to the adopted heat of formation.

Shchukarev and Suvorov⁶ have also derived a log K_p equation for the disproportionation process,

$$2 \text{WOCl}_4(g) \rightarrow \text{WO}_2\text{Cl}_2(g) + \text{WCl}_6(g). \text{ Third law analysis gives } \Delta H_f^o(\text{WO}_2\text{Cl}_2, g) = -160.5 \text{ kcal/mol for the above process. This leads to } \Delta H_f^o(\text{WO}_2\text{Cl}_2, g) = -145.7 \pm 16 \text{ kcal/mol. The second law } \Delta H_f^o \text{ is } 11.0 \text{ kcal/mol. The drift in the third law analysis is } 0.3 \text{ eu.}$$

Heat Capacity and Entropy.

The molecular configuration is assumed to be a distorted tetrahedron of C_{2v} symmetry, similar to that of MoO₂Cl₂(g)¹, and CrO₂Cl₂(g)². The bond distances W-O and W-Cl are estimated to be the same as those in WO₃(g) and WCl₆(g), respectively. The bond angles are assumed to be the same as those in MoO₂Cl₂(g)¹. The three principal moments of inertia are $I_A = 6.419 \times 10^{-38}$, $I_B = 5.342 \times 10^{-38}$ and $I_C = 3.397 \times 10^{-38} \text{ g cm}^2$.

The vibrational frequencies, 984 cm⁻¹ and 972 cm⁻¹, were observed in the infrared spectra by C. O. Barreclough and J. Stala.³ They tentatively assigned these two as the asymmetric and symmetric W-O stretching frequencies. The rest of the frequencies are estimated by comparison with those observed in the infrared and Raman spectra for CrO₂Cl₂(g)^{4,5}. They are not listed in point group order.

Heat of Formation. Recalculated from the data reported by E. J. Salstrom, *J. Am. Chem. Soc.* **55**, 2426 (1933) and A. Wachten, *J. Am. Chem. Soc.* **54**, 2271 (1932).

Heat Capacity, Entropy and Melting Data. C_p (15.8° to 205.5°K.) reported by W. Nemst, *Ann. Physik*, **35**, 335 (1911) and adjusted so that S_{298.15} is equal to the value reported by K. K. Kelley and E. G. King, *U. S. Bur. Mines Bull.* 592 (1961). C_p above 298.15°K. obtained from K. K. Kelley, *U. S. Bur. Mines Bull.* 584 (1960) and joined smoothly to the low temperature heat capacity curve by graphical extrapolation. T_m and ΔH_m obtained from M. Blanc and O. Petit, *Compt. rend.* **249**, 1305 (1959).

Heat of Sublimation. Calculated from vapor pressure data of E. D. Eastman and L. H. Duachak, *U. S. Bur. Mines Tech. Paper* 225 (1919), C. G. Kaiser, *U. S. Bur. Mines Tech. Paper* 360, 28 (1925), H. V. Wartenberg and O. Bogase, *Z. Elektrochem.* **29**, 384 (1922), and M. Jahn-Held and K. Jellinek, *Z. Elektrochem.* **43**, 191 (1937), which are in good agreement. Vapor pressure was also measured by F. Volmer, *Physik. Z.* **30**, 580 (1929), J. L. Barton and H. Bloom, *J. Phys. Chem.* **60**, 1413 (1956), B. Gredner and K. Jellinek, *Z. Physik. Chem.* **A165**, 97 (1933), and K. Mwa, M. Sato and M. Yoshiyama, *J. Faculty Sci. Hokkaido Imp. Univ. Ser. III*, **2**, 17 (1940).

Lead Dichloride (PbCl₂) (Liquid)

Mol. Wt. = 278.12

 ΔH_f° 298.15 = [-81.49] kcal. mole⁻¹ $S_{298.15}^\circ$ = [38.336] cal. deg.⁻¹ mole⁻¹ T_m = 768°K ΔH_m° = 5.70 kcal. mole⁻¹ T_b = 1226°K ΔH_v° = 26.61 ± 0.70 kcal. mole⁻¹Heat of Formation. Calculated from that of the crystal.Heat Capacity, Entropy and Melting Data. C_p reported by M.Bizouard and P. Pauly, Compt. rend. 252, 51 (1961). T_m and ΔH_m° obtained from M. Blanc and G. Petit, Compt. rend. 248, 1305 (1959).

A glass transition temperature of 520°K. is assumed.

Vaporization Phenomena. T_b and ΔH_v° calculated from ΔH_g° 298.15 and functions for condensed and gaseous states.

Lead Dichloride (PbCl₂)

(Ideal Gas) Mol. Wt. = 278.12

 [240] (1)
 [70] (1)
 [300] (1)

Pb-Cl distance = 2.46 ± 0.02 Å ClPbCl angle = 95° $\sigma = 2$
 $I_A = 24.223 \times 10^{-39}$ g. cm.² $I_B = 39.741 \times 10^{-39}$ g. cm.²
 $I_C = I_A + I_B = 62.970 \times 10^{-39}$ g. cm.²

Heat of Formation. Calculated from $\Delta H_f^\circ 298.15$ for PbCl₂(c) and $\Delta H_g^\circ 298.15$.

Heat Capacity and Entropy. Molecular dimensions obtained from L. E. Sutton (ed.), "Tables of Interatomic Distances and Configurations in Molecules and Ions," The Chemical Society, London, 1958. Vibrational frequencies estimated by comparison with the vibrational frequencies for the mercury dihalides.

Point Group C_{2v} $\Delta H_f^\circ = -39.34 \pm 1.0$ kcal/mol $S_{298.15}^\circ = 67.36 \pm 0.5$ gibbs/mol $\Delta H_f^\circ = -39.3 \pm 1.0$ kcal/molSilicon Dichloride (SiCl₂)

o = 2

Heat of Formation

The adopted value is derived from $\Delta H_f^\circ = 78.5 \pm 2$ kcal/mol at 298.15 K for the reaction $\text{Si(c)} + \text{SiCl}_4(\text{g}) \rightarrow 2 \text{SiCl}_2(\text{g})$. JANAF analyses of equilibrium data for this reaction are summarized below. Three sets of data (1, 2, 3) yield average values of ΔH_f° (3rd law) which agree within 0.5 kcal/mol and values of ΔS_f° (2nd law) which are in reasonable agreement with the JANAF functions. Two of the equilibrium studies used flow techniques while the third used a static technique. A median value of ΔH_f° is adopted. Its uncertainty is estimated by assuming that the JANAF entropy for $\text{SiCl}_2(\text{g})$ may be too low by 0.7 gibbs/mol at 1400 K. The adopted value corresponds to ΔH_f° atom = 203.0 kcal/mol and an average bond energy of 101.5 kcal/mol.

Two other flow studies (3, 4) yield large entropy errors, suggesting that there are temperature-dependent errors in Kp. The reported equilibrium constants are reasonable at the lower temperatures but deviate progressively at the higher temperatures. In contrast, the static study of Ishino (5) gave Kp values which differ by a factor of five from the adopted ones. These data yield a consistent entropy but ΔH_f° (3rd law) is lower by 5 kcal/mol.

Heat Capacity and Entropy

The point group is assumed to be the same as that of CF_2 and SiF_2 . The Si-Cl bond length and Cl-Si-Cl bond angle are estimated to be intermediate between those in HSiCl_3 and H_2SiCl_2 . Comparisons with CF_2 , SiF_2 , H_2O , and H_2SiF_2 confirm that the estimated angle is reasonable. Further confirmation of the structure comes from analysis of isotopic splittings in the infrared spectra of matrix-isolated SiCl_2 . Milligan and Jacox (7) deduced angles of 90 to 120° from alternative assignments for the two stretching vibrations. Observations on argon matrices gave 502 and 513 cm⁻¹ for these vibrations, but it was not possible to decide which is the symmetric mode. Principal moments of inertia are $I_A = 31.25 \times 10^{-38}$, $I_B = 5.035 \times 10^{-38}$, and $I_C = 36.29 \times 10^{-38}$ g cm².

Milligan and Jacox (7) also observed an unstructured absorption in the ultraviolet spectrum. This is the region in which gas-phase emission studies (8) showed features tentatively ascribed to SiCl_2^+ . Vibrational spacings of about 250 and 540 cm⁻¹ were associated (8) with the ground state; however, this analysis should be reviewed in the light of the matrix spectra. Meanwhile, we estimate that the bending mode should be similar to that in H_2SiCl_2 , probably 190 ± 40 cm⁻¹.

The ground state is assumed to be 1A_1 , as suggested by Hückel-molecular-orbital calculations (9). Singlet excited states (8, 10) are included near 28000 and 30000 cm⁻¹, but the values are placed in brackets to emphasize the uncertainty in the analysis. Also tentatively adopted is the suggestion by Hastie et al. (10) that the continuous spectrum near 23000 cm⁻¹ is due to a triplet excited state.

Heat of Formation

The heat of formation of $\text{TiCl}_2(\text{c})$ has been measured calorimetrically. The chosen value of ΔH_f° is the average of two such determinations. Values of ΔH_f° are also calculated from the heats of reaction for the processes (A) $2\text{TiCl}_3(\text{c}) = \text{TiCl}_2(\text{c}) + \text{TiCl}_4(\text{g})$, (B) $3\text{TiCl}_3(\text{c}) = 2\text{TiCl}_2(\text{c}) + \text{TiCl}_4(\text{g})$, and (C) $2\text{TiCl}_3(\text{c}) = \text{TiCl}_4(\text{g}) + \text{TiCl}_2(\text{c})$. These heats of reaction are combined with auxiliary JANAF values for the heats of formation of $\text{TiCl}_3(\text{c})$, $\text{TiCl}_4(\text{g})$, $\text{TiCl}_3(\text{c})$ and $\text{TiCl}_2(\text{c})$. The following table summarizes the data used to calculate ΔH_f° .

Heat Capacity and Entropy

The heat capacity of $\text{TiCl}_2(\text{c})$ has been measured by Kim and Stout (8) over the range 6° to 300°K . They calculated the adopted value of S_{298}° from their measurements based on $S_{298}^\circ = 0.017$ eu. The heat capacity above 300°K is estimated by graphical extrapolation. The large uncertainty on S_{298}° is due to the possibility of sizeable electronic contributions to the heat capacity below 6°K which would account for the rather low value of S_{298}° reported by Kim and Stout (8).

Heat of Sublimation

The heat of sublimation is calculated from the heats of formation of $\text{TiCl}_2(\text{c})$ and $\text{TiCl}_2(\text{g})$. The temperature of sublimation is taken as the point at which $\Delta G^\circ = 0$ for the process $\text{TiCl}_2(\text{c}) = \text{TiCl}_2(\text{g})$. These values are hypothetical since TiCl_2 would be decomposed to $\text{TiCl}_3(\text{g})$ and $\text{TiCl}_4(\text{g})$ below this temperature.

Heat of Formation

Gross and Levi (1) have measured the equilibrium $2\text{TiCl}_3(\text{g}) + \text{Ti}(\text{c}) \rightarrow 3\text{TiCl}_2(\text{g})$ at 1723°K and obtain $\Delta G_{1723}^\circ = 21.7$ kcal/mol from four measurements. This yields $\Delta H_{298}^\circ(\text{TiCl}_2, \text{g}) = -56.7 \pm 3$ kcal/mol. They discuss the measurements of Farber and Darnall (2), on the vapor pressure of $\text{TiCl}_2(\text{c})$, and show that the results are probably in error due to disproportionation of $\text{TiCl}_3(\text{g})$ on condensation. In the work of Skinner and Rushwain (3) on the reaction $2\text{NaCl}(\text{g}) + \text{Ti}(\text{c}) = 2\text{Na}(\text{g}) + \text{TiCl}_2(\text{g})$, Gross and Levi indicate that the basic assumption, of conversion to TiCl_2 only, is erroneous. In the third law analysis of both these data sets significant drifts are obtained which tends to confirm the above arguments.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $\text{TiCl}_2(\text{c})$ reported by Benzinger and Rundle (4). The vibrational frequencies are estimated from a valence force field model.

The electronic levels are assumed to correspond to the inverted states of $\text{NiCl}_2(\text{g})$ (5). This linear configuration is adopted, since experimental evidence indicates that other transition metal dihalides are linear (6, 7, 8, 9).

TUNGSTEN DICHLORIDE (WCl₂)

(CRYSTAL)

GF_W = 254.756

Cl₂W

ΔHf° = Unknown

ΔHf°_{298.15} = -61.5 ± 3 kcal/mol

S°_{298.15} = [31.2] gibbs/mol

Td = 862°K

Heat of Formation.

The heat of formation, ΔHf°₂₉₈ (WCl₂, c) = -61.5 ± 3 kcal/mol, is derived from the heat of combustion, ΔHc° = -140 ± 3 kcal/mol for WCl₂(c) + 3/2 O₂(g) → WO₃(c) + Cl₂(g), reported by S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kovs, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin, and A. K. Baev, Zhur. Neorg. Khim. 5, 1650 (1960). The value of ΔHc° was determined calorimetrically, but no further information about the combustion process was given in the paper.

Heat Capacity and Entropy.

CP°₂₉₈ = 6.2 gibbs/g-atom and CP°₉₀₀ = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 900°, which is near the decomposition temperature, the heat capacity is obtained by linear interpolation.

The entropy, S°₂₉₈ = 31.2 eu, is estimated by the method of W. M. Latimer, "Oxidation Potentials," 2nd Ed., Prentice-Hall, Inc., New York, 1952. S. A. Shchukarev et al., loc. cit., have estimated ΔS° = -30 eu for W(c) + Cl₂(g) = WCl₂(c) which leads to S°₂₉₈ (WCl₂, c) = 31.1 eu, using JANAP auxiliary data.

Temperature of Decomposition.

The decomposition temperature is obtained by extrapolation to one atmosphere total pressure of a log P versus 1/T plot of the decomposition pressure data reported by S. A. Shchukarev, G. I. Novikov, and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 10, Ser. Fiz. i Khim., No. 2, 78 (1959). Decomposition pressure data for Cl:W ratios less than two suggest that the decomposition reaction is not simple.

Heat of Formation.

The value of ΔH_f⁰₂₉₈(WCl₂,g) = -3 ± 25 kcal/mol is calculated from the heat of formation of the crystal plus the heat of sublimation, ΔH_s₂₉₈ = 58.5 ± 25 kcal/mol. The latter is estimated from the heats of sublimation of TiCl₂, CrCl₂, MnCl₂, FeCl₂, CoCl₂, NiCl₂ given by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963).

The uncertainty covers the difference between the heats of sublimation among the above compounds and also the possible error in transference from the first row transition metal chlorides to tungsten dichloride.

S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin, and A. K. Beev, Zh. Neorg. Khim. 5, 1650 (1960), have also estimated the heat of sublimation as 102 kcal/mol.

Heat Capacity and Entropy.

The molecular configuration of WCl₂(g) is assumed to be linear. The bond distance is estimated to be the same as that in WCl₆(g). The ground state configuration (⁵Σ_g⁺), the low lying electronic levels and their quantum weights are assumed to be the same as those for CrCl₂(g), observed by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966). The vibrational frequencies are calculated from a valence force field model. The stretching force constant, K₁, is estimated to be the same as that of HgCl₂(g), 2.7 millidynes/Å. The bending force constant is assumed to be one hundredth of the stretching force constant. The moment of inertia is I = 6.013 x 10⁻³⁸ g cm².

Heat of Formation

The value of ΔHf°₂₉₈(ZrCl₂, c) = -103.0 kcal/mol is calculated from the estimated ΔHs°₂₉₈ = 58.5 kcal/mol for ZrCl₂(c) + ZrCl₂(g), using ΔHf°₂₉₈(ZrCl₂, g) = -44.5 kcal/mol (1). The estimated ΔHs°₂₉₈ is obtained as an average of the heats of sublimation at 298°K for TiCl₂, VCl₂, CrCl₂, FeCl₂, NiCl₂ given by L. Brewer, G. R. Somayajulu and E. Brackett (2).

Heat Capacity and Entropy

The heat capacities of ZrCl₂(c) are estimated based on the assumption that Cp(ZrCl₂, c) = 1/2[Cp(ZrCl₄, c) + Cp(Zr, c)]. The entropy, S°₂₉₈, is also estimated in a manner similar to that of the heat capacity.

Melting Data

The melting point was estimated to be 1000°K by L. Brewer (3) and the heat of melting was also estimated by A. Glassner (4).

ZIRCONIUM DICHLORIDE (ZrCl₂) (LIQUID) GFW = 162.126

$$\Delta H_f^{\circ} = [-98.372] \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = [6.4 \pm 3] \text{ kcal/mol}$$

$$\Delta H_v^{\circ} = [45.0] \text{ kcal/mol}$$

$$S_{298.15}^{\circ} = [29.278] \text{ gibbs/mol}$$

$$T_m = [1000]^{\circ}\text{K}$$

$$T_b = [1565.3]^{\circ}\text{K}$$

Heat of Formation

The $\Delta H_f^{\circ}(\text{ZrCl}_2, l)$ is calculated from $\Delta H_f^{\circ}(\text{ZrCl}_2, c)$ by adding ΔH_m° and the difference between $H_{1000} - H_{298}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacities are assumed to be constant at 7.25 gibbs/g-atom. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

The melting point was estimated to be 1000°K by L. Brewer (1), and the heat of melting was also estimated by A. Glasner (2).

Vaporization Data

Tb is the temperature at which the Gibbs energy change approaches zero for the process $\text{ZrCl}_2(l) \rightarrow \text{ZrCl}_2(g)$. The difference between ΔH_f° for $\text{ZrCl}_2(l)$ and $\text{ZrCl}_2(g)$ at Tb is ΔH_v° .

Bond Distance: Zr-Cl = [2.3] Å

Bond Angle: Cl-Zr-Cl = [180°]

Rotational Constant: $B_0 = [0.0494] \text{ cm}^{-1}$ $\sigma = [2]$

Heat of Formation

Potter (1) investigated mass spectrometrically the gaseous equilibria among ZrCl , ZrCl_2 , ZrCl_3 and ZrCl_4 . Ion intensities were measured 2.5 eV above the ionization threshold. Using the reported equilibrium constants for the reaction $\text{ZrCl}_4(g) + \text{ZrCl}_2(g) \rightleftharpoons \text{ZrCl}_3(g)$ in the temperature range 1873-2110°K, second and third law analyses give the heat of reaction at 298°K as -15.6 and -17.7 kcal/mol, respectively. The third law drift is 8.9 ± 3.7 eu. Based on the third law heat of reaction and $\Delta H_f^\circ(\text{ZrCl}_4, g) = -207.77 \text{ kcal/mol}$ (2) and $\Delta H_f^\circ(\text{ZrCl}_3, g) = -125.3 \text{ kcal/mol}$ (3), we obtain $\Delta H_f^\circ(\text{ZrCl}_2, g) = -44.5 \text{ kcal/mol}$ which is adopted in the tabulation.

Ferber et al. (4) also studied mass spectrometrically the reaction (a) $\text{Zr}(c) + \text{ZrCl}_4(g) \rightleftharpoons \text{ZrCl}_3(g)$ and the reaction (b) $\text{Zr}(c) + \text{ZrCl}_2(g) \rightleftharpoons \text{ZrCl}(g)$. They reported second law heats of reaction as $\Delta H_{298}^\circ = 28.6 \pm 1.6 \text{ kcal/mol}$ for reaction (a); and $-141.1 \pm 2.2 \text{ kcal/mol}$ for reaction (b). Third law analysis of the equilibrium constants which were calculated from their ion intensities of run 3 (the only available values) gives $\Delta H_f^\circ(\text{ZrCl}_2, g) = -43.4 \text{ kcal/mol}$. See JANAF $\text{ZrCl}_3(g)$ table (3) for details.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that other transition metal dichlorides are linear (5, 6, 7, 8, 9, 10) even though some fluorides are bent (11). The bond distance is assumed to be the same as that of $\text{ZrCl}_4(g)$. The electronic levels and quantum weights are estimated to be the same as those of $\text{TiCl}_2(g)$ (12).

The vibrational frequencies are calculated from a valence force field model. The stretching force constant is estimated to be 2.5 millidyne/Å and the bending force constant 0.05 millidyne/Å. The moment of inertia is $52.217 \times 10^{-39} \text{ g cm}^2$.

$\Delta H_f^o = -95.80 \pm 0.20$ kcal. mole⁻¹
 ΔH_f^o 298.15 = -95.46 $\pm$ 0.20 kcal. mole⁻¹
 $\Delta H_m^o = 10.30$ kcal. mole⁻¹
 ΔH_g^o (to dimer) = 34.52 kcal. mole⁻¹

$S_{298.15}^o = 34.019$ cal. deg⁻¹ mole⁻¹
 $T_m = 577^\circ K.$

Heat of Formation.

The enthalpy change, ΔH_f^o 298.15 = -24.49 $\pm$ 0.07 kcal. mole⁻¹, for the reaction $Fe() + 3(HCl-12.731 H_2O)(l) + 1/2(H_2O-12.580 H_2O)(l) = FeCl_3(c) + H_2(g) + 45.483 H_2O(l)$ was determined by M. P. Koehler and J. P. Coughlin, J. Phys. Chem. **63**, 605 (1959). This leads to ΔH_f^o 298.15 = -95.48 $\pm$ 0.20 kcal. mole⁻¹ for $FeCl_3(c)$, using ΔH_f^o 298.15 = -38.9 $\pm$ 0.05 and -45.68 $\pm$ 0.01 kcal. mole⁻¹ for hydrochloric acid and hydrogen peroxide solution, respectively, obtained from F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine and I. Jaffe, National Bureau of Standards Circular 500, 1952. From ΔH_f^o 298.15 = -38.0 $\pm$ 0.2 kcal. mole⁻¹ for the reaction $FeCl_3(c) = Fe^{++}(aq.)$ reported by J. C. M. Li and N. W. Gregory, J. Am. Chem. Soc. **74**, 4670 (1952), the value of ΔH_f^o 298.15 ($FeCl_3, c$) was calculated as -93.26 $\pm$ 0.2 kcal. mole⁻¹. The former ΔH_f^o 298.15 value is adopted.

The equilibrium pressures of the reaction $2 FeCl_2(c) + Cl_2(g) = 2FeCl_3(c)$, in the temperature range of 435.7-482.2°K., were measured by H. Schäfer and E. Oehler, Z. anorg. allgem. Chem. **271**, 206 (1953). Using the reported partial pressures for $Cl_2(g)$, the enthalpy change (ΔH_f^o 298.15) of the reaction was evaluated as -27.43 $\pm$ 0.44 and -27.21 kcal. mole⁻¹ by the second and third law methods, respectively. Based on the third law value for ΔH_f^o 298.15, the value of ΔH_f^o 298.15 ($FeCl_3, c$) was derived to be -95.36 $\pm$ 0.12 kcal. mole⁻¹ which is in good agreement with the adopted value.

Heat Capacity and Entropy.

The low temperature (51-298.15°K.) heat capacities and high temperature (339.6-560.9°K.) heat content of $FeCl_3(c)$ were determined by S. S. Todd and J. P. Coughlin, J. Am. Chem. Soc. **73**, 4184 (1951). The low temperature C_p and the derived high temperature C_p were plotted. The two C_p curves were joined smoothly at 298°K. The C_p values above 560.9°K. were obtained by graphical extrapolation. The value of $S_{298.15}^o$ was derived from the low temperature data reported by S. S. Todd and J. P. Coughlin, loc. cit., using $S_{51}^o = 6.29$ cal. deg⁻¹ mole⁻¹. The value of $S_{298.15}^o$ was selected to make the second and third law values of ΔH_f^o , derived from the equilibrium data reported by H. Schäfer and E. Oehler, loc. cit., in good agreement. The difference in $S_{298.15}^o$ between the selected value, 6.29, and the reported value, 4.50 cal. deg⁻¹ mole⁻¹, by S. S. Todd and J. P. Coughlin, loc. cit., is assumed to be the magnetic entropy remaining at 51°K. which was unaccounted for in the report.

Melting Data.

T_m and ΔH_m^o were obtained from S. S. Todd and J. P. Coughlin, loc. cit.

Heat of Sublimation.

The difference between ΔH_f^o 298.15 for $Fe_2Cl_6(g)$ and $2FeCl_3(c)$ is the heat of sublimation at 298.15°K. The former is obtained by the second and third law analyses of related equilibrium data. See $Fe_2Cl_6(g)$ table for details.

IRON TRICHLORIDE (FeCl₃) (LIQUID) MOL. WT. = 162.206

S_{298.15} = 47.955 cal. deg.⁻¹ mole⁻¹
ΔH_f[°] 298.15 = -86.713 kcal. mole⁻¹
ΔH_m[°] = 10.30 kcal. mole⁻¹
ΔH_f[°](to dimer) = 10.46 kcal. mole⁻¹
T_m = 577°K.
T_b = 605°K.

Heat of Formation.

The value of ΔH_f[°] 298.15(FeCl₃, l) was obtained from ΔH_f[°] 298.15(FeCl₃, c) by adding ΔH_m[°] and the difference between H_m[°] - H_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity for FeCl₃(l) was taken from S. S. Todd and J. P. Coughlin, J. Am. Chem. Soc. 73, 4184 (1951) and assumed as constant between 298.15° and 1500°K. The entropy (S_{298.15}) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and ΔH_m[°] were reported by S. S. Todd and J. P. Coughlin, loc. cit.

Vaporization Data.

The boiling point (T_b) is determined as the temperature at which the free energy change (ΔG_p[°]) of the reaction 2FeCl₃(l) = Fe₂Cl₆(g) approaches zero. The corresponding enthalpy change at T_b is the heat of vaporization (ΔH_v[°]).

Bond Distance: Fe-Cl = [2.17] Å

Bond Angle: Cl-Fe-Cl = [120]°

Product of the Moments of Inertia: I_AI_BI_C = [1.43769 × 10⁻¹¹²] g.³ cm.⁶

σ⁻ = [8]

Heat of Formation.

The equilibrium pressures for the reaction Fe₂Cl₆(g) = 2FeCl₃(g) were determined by Kangro and Bernstorff¹ and Schiffer², respectively. Using their vapor pressure data the corresponding values of ΔH_f⁰ 298.15 for that reaction were evaluated by both the second and third law methods. Based on the third law values for ΔH_f⁰ 298.15, the heat of formation (ΔH_f⁰ 298.15) for FeCl₃(g) were derived. The results obtained are presented as follows.

Investigator	Temperature, °K.	Second Law Value	Third Law Value	ΔH _f ⁰ 298.15 kcal. mole ⁻¹
Kangro and Bernstorff ¹	760.2-1014.2	34.99 ± 0.44	35.73	-60.34 ± 0.30
Schiffer ²	673.2-1073.2	34.81 ± 0.02	34.93	-60.74 ± 0.20

¹ W. Kangro and H. Bernstorff, Z. anorg. allgem. Chem. **253**, 318 (1950).

² H. Schiffer, Z. anorg. allgem. Chem. **259**, 53 (1949).

The adopted value of ΔH_f⁰ 298.15(FeCl₃ g) is -80.5 ± 1.2 kcal. mole⁻¹.

Heat Capacity and Entropy.

The molecular structure was assumed to be the same as that of AlCl₃(g) due to the similarities in structure between Fe₂Cl₆(g) and Al₂Cl₆(g). The Fe-Cl bond distance was estimated by comparison with those for Fe₂Cl₆(g) reported by E. Z. Zasorin, N. G. Rambidi and P. A. Akishin, Zh. Strukt. Khim., **4**, 910 (1963) and O. Heasel and H. Viorvöll, Acta Chem. Scand., **1**, 149 (1947). Both the ground state quantum weight and vibrational frequencies were estimated so that the second and third law values of ΔH_f⁰ 298.15, derived from the vapor pressure data, for the reaction Fe₂Cl₆(g) = 2FeCl₃(g) are in reasonable agreement. The three principal moments of inertia are: I_A=1.43769 × 10⁻¹¹² g. cm.² and I_C = 8.31588 × 10⁻³⁸ g. cm.²

Si-H dist. = 1.48

all angles = [109° 28']

Si-Cl dist. = 2.02

Product of Moments of Inertia: I_AI_BI_C = 75.642 X 10⁻¹¹⁴ g.³ cm.⁶

Heat of Formation. ΔH_f^o 298.15 was calculated from heats of reaction reported by E. Wolf, Z. Anorg. u. Allgem. Chem. 313, 228 (1961) for the equation

SiHCl₃(g) + 5NaOH(c) = Na₂SiO₃(c) + 3NaCl(c) + 2H₂O(l)

Heat Capacity and Entropy. Molecular constants were found in Janz and Mikawa, Bull. Chem. Soc. Japan 34, 1495 (1961). Vibrational frequencies can also be found in Henderson and Schaeffer, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data," January, 1960.

June 30, 1962

Lithium Chloride, Trimeric (LiCl)₃ (Ideal Gas)

Mol. Wt. = 127.19

ΔH_f^o 298.15 = -240.134 + 5 kcal. mole⁻¹S_{298.15}^o = 180.223 cal. deg.⁻¹ mole⁻¹298.15 = 180.223 cal. deg.⁻¹ mole⁻¹Point Group = D_{3h}

Vibrational Levels and Multiplicities

 ω_e , cm.⁻¹
[650] {8}
[220] {6}Bond distances and angles
Li-Cl distance = [2.2] Å
Li-Cl-Li angle [120°]
Plane cyclic structure σ = 6Moment of Inertia I_AI_BI_C = 2.675 × 10⁻¹¹² g.³ cm.⁶Heat of Formation. The heat of sublimation at 298° was chosen so as to give the correct ratio of monomer, dimer and trimer at 870°K. The value used was 52.6 kcal. mole⁻¹, which compares very well with the value 53.6 kcal. mole⁻¹ obtained from a third law analysis of the data of An. N. Nesmeyanov and L. A. Sazonov, Zhur. Neorg. Khim. 4, 231 (1960) in conjunction with the relative concentrations of monomer, dimer, and trimer at 870°K from the work of R. C. Millar and P. Kusch, J. Chem. Phys. 25, 860 (1950).

Heat Capacity and Entropy. The postulated structure, bond lengths and frequencies were all taken from D. L. Hildenbrand, A. M. Saul P. R. Basford, S. E. Stephenson, L. Larson and A. Uyehara, Aero-nutronics Panth Quarterly Report on Contract NORD 17890 Report C-898 (1960).

Phosphoryl Chloride (POCl₃)

Heat of Formation.

The ΔH_f^o 298.15 for POCl₃(g) was derived from the ΔH_f^o 298.15 of POCl₃(l) and the ΔH_v^o 298.15 of the POCl₃(l) was calculated from the heat of hydrolysis observed by T. Charnley and H. A. Skinner, J. Chem. Soc., 450, (1953) for the reaction:

The auxiliary thermochemical data, on the heats of formation of water and aqueous solutions of HCl and of H₃PO₄, were taken from the National Bureau of Standards, "Selected Values of Chemical Thermodynamic Properties," Circular 500, and were adjusted for consistency with JANAF tables. The heat of vaporization was measured and corrected to 298.15°K by J. B. Ott and W. F. Glaque, J. Am. Chem. Soc., 82, 1308 (1960). A correction was made for the change in phosphorus reference state [white (α) → red (v)].

Heat Capacity and Entropy.

The molecular constants are from the microwave spectral data of Q. Williams, J. Sheridan, and W. Gordy, J. Chem. Phys., 20, 164 (1952). In order to determine the structure Williams et al. (loc. cit.) assumed the P-Cl distance equal to 1.99 Å. This was the smallest value allowed (2.02 ± 0.03 Å) by the electron diffraction work of L. O. Brockway and J. Y. Beach, J. Am. Chem. Soc., 60, 1836 (1938).

Ott and Glaque (loc. cit.) have given the moments of inertia obtained from a weighted average of the isotopic species. I_A ≠ I_B due to isotopic loss of asymmetry. The S_{298.15} calculated from calorimetric data by Ott and Glaque (loc. cit.) was 77.75 cal. deg⁻¹ mole⁻¹ and the S_{298.15} calculated from the spectral data was 77.77 cal. deg⁻¹ mole⁻¹.

Heat of Formation

Neale and Williams (1) measured the heat of hydrolysis of liquid phosphorus trichloride and reported a $\Delta H_f^\circ = -67.5 \pm 0.3$ kcal/mol for the following reaction:

with X_2 in range 4500 to 7500. Combining this result with heat of formation data for aqueous H_3PO_3 , -223.4 kcal/mol (2, 5, 16), H_2O (2), and aqueous HCl (2) we derive $\Delta H_f^\circ(\text{PCl}_3, \ell) = -76.7$ kcal/mol. Charnley and Skinner (3) made an independent investigation of the hydrolysis of liquid phosphorus trichloride and obtained enthalpy data in very good agreement with Neale and Williams' results. Their results lead to $\Delta H_f^\circ(\text{PCl}_3, \ell) = -76.5$ kcal/mol when combined with heat of formation data (2, 5, 16).

Neale and Williams (4) also investigated the hydrolysis of liquid phosphorus trichloride in aqueous bromine solution with the formation of phosphoric acid rather than phosphorous acid which results when hydrolysis occurs in water. They reported a $\Delta H_f^\circ = -137.9$ kcal/mol for the following reaction:

with X_2 in range 3500 to 6300. Combining this result with the following heat of formation data:

$$\Delta H_f^\circ(\text{H}_3\text{PO}_4 \cdot \text{H}_2\text{O}) = -308.4 \pm 0.5 \text{ kcal/mol (5)}$$

$$\Delta H_f^\circ(\text{Br}_2(\text{aq})) = -0.2 \text{ kcal/mol (6)}$$

$$\text{HCl}(\text{aq}) \text{ and } \text{HBr}(\text{aq}) (2)$$

along with dilution data for $\text{H}_3\text{PO}_4(\text{aq})$ (2), we derive $\Delta H_f^\circ(\text{PCl}_3, \ell) = -77.0$ kcal/mol.

The heat of formation from white phosphorus of gaseous PCl_3 , $\Delta H_f^\circ(\text{PCl}_3, g) = -69.0 \pm 1.1$ kcal/mol, is calculated from the heat of formation of the liquid, $\Delta H_f^\circ(\text{PCl}_3, \ell) = -76.7 \pm 1.0$ kcal/mol, an average value of the three results given above, and the heat of vaporization of PCl_3 . The heat of vaporization of the liquid, $\Delta H_{\text{vap}}^\circ = 7.7 \pm 0.1$ kcal/mol, is determined from a second law analysis of the combined vapor pressure data of Niselson and Saryakov (7) and Regnault (8). The smoothed vapor pressure data of Regnault as reported by Stull (9) were used. Converting to the Pred, V standard state with a $\Delta H_{\text{trans}}^\circ = 4.2 \pm 0.2$ kcal/mol (10), we derive $\Delta H_f^\circ(\text{PCl}_3, g) = -64.8 \pm 1.3$ kcal/mol.

An independent value for the heat of formation can be obtained from the work of Dusa and Mykityuk (12) on the reaction $1.5\text{CaF}_2 + \text{PCl}_3(g) \rightarrow 1.5\text{CaCl}_2 + \text{PF}_3(g)$. The authors report $\Delta H_{300}^\circ = -2.97$ kcal. From a reexamination of their technique we believe that this heat evolution is likely to be too small, perhaps by 1001. The analytical results indicate that the reaction is 93% complete or better; thus, we can use this with JANAF entropies to calculate $\Delta H_{298}^\circ \leq -3.55$ kcal. Finch et al. (19) have reported $\Delta H_f^\circ(\text{CaF}_2, c) - \Delta H_f^\circ(\text{CaCl}_2, c) = -100.87 \pm 0.02$ kcal/mol; thus, we obtain $\Delta H_f^\circ(\text{PCl}_3, g) \geq -70.1 \pm 2.0$ kcal/mol from $\Delta H_{298}^\circ(\text{PF}_3, g) = -724.9 \pm 0.9$ kcal/mol. This value is not adopted because of the lack of calorimeter calibration, but it offers an attractive possibility for further study.

Heat Capacity and Entropy

The molecular structure and bond length given above for PCl_3 are from the electron diffraction studies of Hedberg and Iwasaki (11). The adopted values are in good agreement within experimental error with the following structural data reported by Kialuk and Townes (12) from microwave studies: $r_{\text{P-Cl}} = 2.043 \pm 0.003$ Å, the angle $\text{Cl-P-Cl} = 100.6^\circ \pm 20'$. The vibrational frequencies are from the recent infrared and Raman studies of Frankiss and Miller (13) and are in excellent agreement with those of Miller et al. (14) and Davis and Oetjen (15). Individual moments of inertia calculated from the electron diffraction data are: $I_A = I_B = 32.393 \times 10^{-39}$ g cm², and $I_C = 57.673 \times 10^{-39}$ g cm².

Dec. 31, 1960; Sept. 30, 1962

Thiophosphoryl Chloride (PSCl₃)
(Ideal Gas)

Mol. Wt. = 169.412

ΔH°_f 298.15 = [-86.8] kcal. mole⁻¹

S°_{298.15} = 80.60 cal. deg.⁻¹ mole⁻¹

Point Group C_{3v}

Vibrational Frequencies and Degeneracies

ω, cm. ⁻¹	ω, cm. ⁻¹	ω, cm. ⁻¹
169 (2)	[247] (2)	247 (1)
431 (1)	540 (2)	751 (1)

Bond distance P-S = 1.65 ± 0.02 Å P-Cl = 2.02 ± 0.01 Å σ = 3
Cl-P-Cl angle = 100.5° ± 1° I_AI_BI_C = 2.0690 × 10⁻¹¹² g.³ cm.⁶

Heat of Formation. ΔH°_f 298 was estimated by C. B. Henderson and R. S. Scheffee, Atlantic Research Corporation, Alexandria, Virginia, "Survey of Thermochemical Data," January 1960. Henderson and Scheffee (loc. cit.) use white(α) phosphorus as a reference state. Their estimated ΔH°_f 298 was adjusted to the Red (V) phosphorus reference state [see white(α) phosphorus sheet.]

Heat Capacity and Entropy. J. S. Zimek and E. A. Plotrowski, J. Chem. Phys. 34, 1087 (1961) have chosen the most probable values for the wave numbers from the infrared spectral data of G. Cilento, D. A. Ramsey, and R. N. Jones, J. Am. Chem. Soc. 71, 2753 (1949), and the Raman spectral data of A. Simon and O. Schulze, Naturwissenschaften 25, 669 (1937); V. N. Matthe, Nature 139, 469 (1936); H. Gerding and R. Hestrick, Rec. trav. chim. 61, 842 (1942); and M. Delvaule and F. Francola, Compt. Rend. 220, 817 (1945). Zimek and Plotrowski (loc. cit.) found their normal coordinate treatments gave the listed wave numbers as fundamentals and lent support for the 247 cm.⁻¹ band missing from the Raman spectral data. The structure (bond distances and angles) was determined from microwave data by Q. Williams, J. Sheridan, and W. Gordy, J. Chem. Phys. 20, 164 (1952).

Silicon Trichloride (SiCl₃)

Vibrational Frequencies and Degeneracies

ω_e , cm ⁻¹	ω_e , cm ⁻¹
470 (1)	582 (2)
[240] (1)	[175] (2)

Bond Distance: Si-Cl = [2.02] Å

Bond Angle: Cl-Si-Cl = 110.9°

Product of the Moments of Inertia: $I_A I_B I_C = [7.5469 \times 10^{-113}] \text{ g cm}^6$ $\sigma = 3$

Heat of Formation

The adopted value is derived from an average bond energy of $\Delta H_{\text{atom}}^\circ/3 = 96 \pm 3 \text{ kcal/mol}$. This value is estimated by comparison of average bond energies for M_n where M = C or Si, X = F or Cl, and n = 2, 3 or 4. These comparisons suggest that the average bond energy for SiCl_3 should be bracketed by those for SiCl_4 and SiCl_2 , i.e. 94.3 and 101.5 kcal/mol, respectively. Alternative estimates from linear plots of $\Delta H_f^\circ(\text{SiCl}_n)$ versus ΔH_f° for SiF_4 , CCl_4 , and CF_4 yield -96, -96, and -96 kcal/mol for ΔH_f° of SiCl_3 at 298.15°K. These agree with the adopted value of -86 ± 10 kcal/mol, which corresponds to $\Delta H_{\text{atom}}^\circ = 288 \pm 10 \text{ kcal/mol}$.

Kerr et al. (1) reported relative rates for several reactions of SiCl_3 , but the authors state that no absolute activation energies are known for reactions of this radical. This precludes derivation of thermochemical values from the kinetic studies. Recently, however, Vurzel et al. (2) reported studies of the decomposition of SiCl_4 by adiabatic compression. Rate constants, as reported in Chemical Abstracts, led to an activation energy of $88 \pm 5 \text{ kcal/mol}$ for $\text{SiCl}_4 \rightarrow \text{SiCl}_3 + \text{Cl}$. This activation energy for recombination should be very close to zero, so $\Delta H_f^\circ = 88 \pm 5$ compared with the adopted result of 86 ± 10 at room temperature. Steele et al. (3) derived an average value of $\Delta H_f^\circ(\text{SiCl}_3) = 93 \pm 4 \text{ kcal/mol}$ from an interpretation of electron impact studies on several molecules. Using $\Delta H_f^\circ(\text{Cl}_3\text{SiH}, g) = -122.6 \text{ kcal/mol}$ (3), we calculate $\Delta H_f^\circ(\text{SiCl}_3) = -82 \text{ kcal/mol}$ and estimate the uncertainty as about 10 kcal/mol.

Heat Capacity and Entropy

Jacob and Milligan (5) studied the formation of SiCl_3 by photolysis of HSiCl_3 trapped in matrices of argon, nitrogen and CO. The two stretching fundamentals were assigned from the infrared spectra. Isotopic splittings were found to be consistent with an angle of $72 \pm 5^\circ$ between the threefold axis and each of the Si-Cl bonds. This yields a bond angle of 110.9° which is similar to that of HSiCl_3 . Non-planarity of SiCl_3 is consistent with the electron-spin-resonance studies of Poinc (6).

We adopt the results of Jacob (5) and estimate the bond length and two bending vibrations by analogy with HSiCl_3 . Similar analogies are reliable for SiF_3 and CF_3 . The ground state quantum weight is taken as two, but excited electronic levels are neglected. Jacob (5) observed unstructured absorptions corresponding to excitation energies of 30000-34500 cm⁻¹ and 41000-46000 cm⁻¹. Principal moments of inertia are $I_A = 65.18 \times 10^{-39}$ and $I_B = I_C = 34.03 \times 10^{-39} \text{ g cm}^2$.

TITANIUM TRICHLORIDE (TiCl₃)

(CRYSTAL)

GFW = 154.259

$$\Delta H_f^\circ = -173.1 \pm 1.0 \text{ kcal/mol}$$

$$\Delta H_f^\circ_{298.15} = -172.5 \pm 1.0 \text{ kcal/mol}$$

$$\Delta H^\circ = 0 \text{ kcal/mol}$$

$$\Delta H_g^\circ = [39.71] \text{ kcal/mol}$$

$$S^\circ_{298.15} = 33.4 \pm 0.3 \text{ gibbs/mol}$$

$$T_f = 220.1^\circ\text{K}$$

$$T_g = [1104.1]^\circ\text{K}$$

Heat of Formation

The heat of formation, ΔH_f° , of TiCl₃(c) has been measured by several investigators. The results of these measurements are as follows.

Investigator	Method	ΔH_f° kcal/mol
Schaffer et al. (1954) (1)	Calorimetric, TiCl ₄ + Hg = TiCl ₃ + 1/2Hg ₂ Cl ₂	-171.8, -172.4
Clifton and MacLeod (1956) (2)	Solution calorimetric	-172.4
Johnson et al. (1956) (3)	Calorimetric, TiCl ₄ (l) + Hl(g) = TiCl ₃ (c) + HCl(g) + 1/2I ₂	-172.5
Krievie et al. (1956) (4)	Solution calorimetric	-171.3
Krievie and Mason (1956) (5)	Equilibrium, TiCl ₃ (c) + HCl(g) = TiCl ₄ (g) + 1/2H ₂ (g)	-172.9
Altman et al. (1956) (6)	Equilibrium, Ti(c) + 3TiCl ₄ (g) = 4TiCl ₃ (c)	-169.4, -171.0
Head (1960) (7)	Equilibrium, 2TiCl ₄ (2) + H ₂ (g) = 2TiCl ₃ (c) + 2HCl(g)	-172.3
	TiCl ₄ (l) + Hg(c) = 1/2Hg ₂ Cl ₂ (c) + TiCl ₃ (c)	
	TiCl ₄ (l) + Ag(c) = AgCl(c) + TiCl ₃ (c)	

The chosen value of -172.5 ± 1.0 kcal/mol is that reported by Johnson et al. (3).

Heat Capacity and Entropy

The heat capacity and entropy of TiCl₃(c) has been measured over the temperature range 54° to 1000°K by King et al. (8). The value of S°_{298} is calculated from these data based on $S^\circ_{51} = 4.29 \text{ eu}$.

Transition Data

A second order transition at 220.1°K was observed by King et al. (8). The heat capacity at this temperature is in excess of 146.8 gibbs/mol. King et al. measured the value of $H^\circ_{240} - H^\circ_{200}$ as 1.213 kcal/mol.

Heat of Sublimation

The heat of sublimation is calculated from the heats of formation of TiCl₃(c) and TiCl₃(g) at the sublimation temperature. The sublimation temperature is taken as the point at which $\Delta G_r = 0$ for the process TiCl₃(c) = TiCl₃(g).

Products of the Moments of Inertia: I_AI_BI_C = (1.33 × 10⁻¹¹) g³ cm⁶

Heat of Formation
The heat of formation of TiCl₃(g) is calculated from the heats of reaction for the processes, (A) 3TiCl₄(g) + Ti(c) = 4TiCl₃(g) and (B) TiCl₃(c) = TiCl₃(g), combined with auxiliary JANAF heats of formation for TiCl₄(g), TiCl₃(c) and Ti(c). Equilibrium measurements of reaction (A) have been reported by Gross and Levi (1). Vapor pressure measurements for reaction (B) have been reported by Sanderson and MacKinnon (2) and by Farber and Barnall (3). Second and third law analyses of these data yield the following results.

Source	Reaction	No. Points	Range, °K	ΔH _f ²⁹⁸ , kcal/mol	Second Law	Third Law	Drift, eu	ΔH _f ²⁹⁸ *
Gross and Levi (1)	A	3	1223			31.6 ± 2.0		-128.5
Sanderson and MacKinnon (2)	B	9**	628-823			42.8 ± 1.1		-129.3
Farber and Barnall	B	8	636-732			45.3 ± 2.1		-126.2

*Calculation based on third law ΔH_f²⁹⁸.
**One point rejected due to failure of statistical test.

The chosen value of ΔH_f²⁹⁸ is -128.9 kcal/mol. This value is the average of the first two determinations.

Heat Capacity and Entropy
The interatomic distance is estimated from that of the solid, given as 2.46 Å by Matta et al. (4), and from comparisons of bond distances of crystal and gas phase tetrahalides of titanium. The pyramidal bond angle is estimated assuming TiCl₃(g) similar to the group V trihalides. The principal moments of inertia are I_A = I_B = 4.28 × 10⁻³⁸ g cm² and I_C = 7.26 × 10⁻³⁸ g cm². The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti³⁺ (5).

Cl₃Zr

GFV = 197.579

(CRYSTAL)

ZIRCONIUM TRICHLORIDE (ZrCl₃)Zirconium Trichloride (ZrCl₃)

GFV = 197.579

(Crystal)

 $\Delta H_f^\circ = \text{Unknown}$ $\Delta H_f^\circ_{298.15} = (-170.7 \pm 15) \text{ kcal/mol}$ $\Delta H_f^\circ_{298.15} = (-104.4) \text{ kcal/mol}$ $S_{298.15}^\circ = (34.8 \pm 3) \text{ gibbs/mol}$ $T_s = (1045.9)^\circ\text{K}$ Heat of Formation

Turnbull and Watts (1) determined the equilibrium pressures for the disproportionation of $\text{ZrCl}_3(\text{c})$ in the temperature range from 613°K to 723°K by a modified dew point technique. Third law and second law analyses of their vapor pressure-temperature equation give the same heat of reaction $\Delta H_{298}^\circ = 30.7 \text{ kcal/mol}$ for $2\text{ZrCl}_3(\text{c}) \rightarrow \text{ZrCl}_2(\text{c}) + \text{ZrCl}_4(\text{g})$.

The adopted value, $\Delta H_{298}^\circ(\text{ZrCl}_3, \text{c}) = -170.7 \text{ kcal/mol}$, is calculated from the heat of reaction at 298°K, and $\Delta H_{298}^\circ(\text{ZrCl}_4, \text{g}) = -207.77 \text{ kcal/mol}$ (2) and $\Delta H_{298}^\circ(\text{ZrCl}_2, \text{c}) = -103 \text{ kcal/mol}$ (3). The assigned uncertainty, $\pm 15 \text{ kcal/mol}$ is mainly due to the uncertainty in the heat of formation of $\text{ZrCl}_2(\text{c})$, and also the dew point technique used.

Heat Capacity and Entropy

The heat capacities of $\text{ZrCl}_3(\text{c})$ are estimated from the Cp values of $\text{ZrCl}_4(\text{c})$ by deduction of one Cl atom Cp contributions which are calculated as $1/4(\text{Cp}(\text{ZrCl}_4, \text{c}) - \text{Cp}(\text{Zr}, \text{c}))$. The S_{298}° is calculated as 34.85 eu based on the assumption that $S_{298}^\circ(\text{ZrCl}_3, \text{c}) = S_{298}^\circ(\text{ZrCl}_4, \text{c}) - 1/4(S_{298}^\circ(\text{ZrCl}_4, \text{c}) - S_{298}^\circ(\text{Zr}, \text{c}))$.

Heat of Sublimation

The heat of sublimation is calculated from the difference in the heats of formation of gas and crystal at 298°K. The sublimation temperature is taken as the point at which $\Delta G^\circ = 0$ for $\text{ZrCl}_3(\text{c}) = \text{ZrCl}_3(\text{g})$.

Heat of Formation

Potter (1) investigated mass spectrometrically the equilibrium $\text{CaCl}_2(\text{g}) + \text{ZrCl}_4(\text{g}) \rightleftharpoons \text{CaCl}_2(\text{g}) + \text{ZrCl}_3(\text{g})$ in the temperature range 1163-1557°K. Ion intensities were measured 2.5 eV above threshold and they were used in the calculation of equilibrium constants. Using the reported equilibrium constants, the heats of reaction at 298°K are evaluated by the third law and second law methods as -3.69 and -16.67 kcal/mol, respectively. The third law drift is 9.31 ± 1.25 eu. Using the third law $\Delta H_f^\circ = -3.69 \text{ kcal/mol}$, $\Delta H_f^\circ(\text{ZrCl}_4, \text{g}) = -207.77 \text{ kcal/mol}$ (2), $\Delta H_f^\circ(\text{CaCl}_2, \text{g}) = -28.8 \text{ kcal/mol}$ (3) and $\Delta H_f^\circ(\text{ZrCl}_3, \text{g}) = -115.0 \text{ kcal/mol}$ (4). We obtain $\Delta H_f^\circ(\text{ZrCl}_3, \text{g}) = -125.3 \text{ kcal/mol}$, which is adopted in the tabulation.

Farber et al. (5) also studied mass spectrometrically the reaction $\text{Zr}(\text{Cl}) + \text{ZrCl}_4(\text{g}) \rightleftharpoons \text{ZrCl}_3(\text{g}) + \text{ZrCl}_2(\text{g})$ in the temperature range from 1579°K to 1779°K. They reported a second law heat of reaction as $\Delta H_f^\circ = 59.2 \pm 1.6 \text{ kcal/mol}$. Since the attainment of equilibrium was questionable in their studies, the heat of reaction obtained from the third law method is generally more reliable. Using their reported ion intensities of run 3 (temperature range from 1667°K to 1698°K, five points), we have calculated the equilibrium constants $K_1 = (I_{\text{ZrCl}_2})^2 / (I_{\text{ZrCl}_3}) (I_{\text{ZrCl}_4})$ for reaction (1) $\text{ZrCl}_3(\text{g}) + \text{ZrCl}_2(\text{g}) \rightleftharpoons \text{ZrCl}_4(\text{g})$, and $K_2 = (I_{\text{ZrCl}_3})^2 / (I_{\text{ZrCl}_4}) (I_{\text{ZrCl}_2})$ for reaction (2) $\text{ZrCl}_3(\text{g}) + \text{ZrCl}_2(\text{g}) \rightleftharpoons \text{ZrCl}_4(\text{g})$. Third law analyses of the equilibrium constants give $\Delta H_f^\circ = -11.0 \text{ kcal/mol}$ for reaction (1) and its drift 4.1 ± 1.7 eu; and $\Delta H_f^\circ = 1.4 \text{ kcal/mol}$ for reaction (2) and its drift 11.1 ± 1.2 eu. Using the third law heats of reaction, and $\Delta H_f^\circ(\text{ZrCl}_4, \text{g}) = 49.1 \text{ kcal/mol}$ (5) and $\Delta H_f^\circ(\text{ZrCl}_3, \text{g}) = -207.77 \text{ kcal/mol}$ (2), we obtain $\Delta H_f^\circ(\text{ZrCl}_2, \text{g}) = -124.9 \text{ kcal/mol}$ and $\Delta H_f^\circ(\text{ZrCl}_2, \text{g}) = -43.4 \text{ kcal/mol}$ which are in good agreement with the values adopted.

Heat Capacity and Entropy

The molecular structure is assumed to be a pyramid similar to the group VA trichlorides. The bond distance is assumed to be the same as that of $\text{ZrCl}_4(\text{g})$. The three principal moments of inertia are $I_A = I_B = 45.9145 \times 10^{-39}$ and $I_C = 72.6247 \times 10^{-39} \text{ g cm}^2$. The electronic levels are estimated as three times higher than those of $\text{TiCl}_3(\text{g})$, based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by C. E. Moore (7). The quantum weights are assumed to be the same as those of $\text{TiCl}_3(\text{g})$.

Vibrational frequencies are calculated from the estimated force constants by the valence force method (8). The force constants are estimated from those of PCl_3 , AsCl_3 , and SbCl_3 listed by Herzberg (8).

Heat of Formation

References relative to the monomer-dimer ratio in magnesium chloride vapor are given in the discussion for monomeric ideal gas. The selected best value for the heat of dimerization at 900°K is -39.2 kcal/mol. Combined with heat of formation data for the monomer and the heat capacity of the dimer, this yields ΔH_{f,298.15}^o = -228.10 kcal/mol.

Heat Capacity and Entropy

A planar structure with D_{2h} symmetry was assumed, with the outer Mg-Cl distance the same as in MgCl₂ and the ring Mg-Cl distance slightly larger. The ring was taken to be square, and the Cl-Mg-Cl' angle 135°. This structure gives individual moments of inertia of I_A = 31.12 × 10⁻³⁹ g cm², I_B = 191.61 × 10⁻³⁹ g cm² and I_C = I_A + I_B.

A reasonable set of frequencies was estimated by comparison with MgCl₂ monomer and other dimer molecules. The single observed frequency is from A. Buchler and W. Klemperer, J. Chem. Phys. 29, 121 (1958), who erroneously ascribed it to the bending mode of the monomer. The estimated values were adjusted until the entropy of dimerization at 900°K was -29.9 gibbs/mol, as selected in the discussion for ideal monomeric gas. The calculated thermodynamic properties of monomer and dimer give total vapor pressures in good agreement with experiment and yield a boiling point for magnesium chloride of 1624°K at one atmosphere pressure.

Molybdenum Tetrachloride (MoCl₄)

(Crystal)

GFW = 237.752

$$\Delta H_f^\circ = \text{Unknown}$$

$$\Delta H_{f298.15}^\circ = -114 \pm 2 \text{ kcal/mol}$$

$$\Delta H_m^\circ = [4 \pm 2] \text{ kcal/mol}$$

$$S_{298.15}^\circ = [53.5 \pm 3] \text{ gibbs/mol}$$

$$T_m = 590^\circ\text{K}$$

Heat of Formation

The adopted $\Delta H_f^\circ = -114$ kcal/mol was determined by Shchukarev et al. (1) by solution calorimetry. The authors measured the heat of solution of MoCl₄ in the aqueous solvent FeCl₃ + HCl and obtained the heat of formation from a comparison with the heat of solution of MoCl₅ measured in the same solvent.

The decomposition pressures of 2MoCl₅(c) = 2MoCl₄(c) + Cl₂(g) (80 - 150°C) were measured manometrically by Saeki and Matsuzaki (2). From the reported data we evaluate the enthalpy change for the above reaction by third law analysis.

Based on $\Delta H_{f298}^\circ(\text{MoCl}_5, c) = -126$ kcal/mol and the third law $\Delta H_{f298}^\circ = 24.132$ kcal/mol, we obtain $\Delta H_{f298}^\circ(\text{MoCl}_4, c) = -113.94$ kcal/mol, which is in very good agreement with the value reported by Shchukarev et al. (1).

Heat Capacity and Entropy

The heat capacity is estimated by comparison with that of WCl₄(c). The estimated $S_{298}^\circ = 53.5$ eu is based on the assumption that the entropy differences between MoCl₄(c) and MoCl₅(c) is about the same as that between WCl₄(c) and WCl₅(c). The entropy obtained from the second law analysis of the data of Saeki and Matsuzaki (2) agrees with the adopted one within the error of the vapor pressure data.

Melting Data

See liquid table.

Molybdenum Tetrachloride (MoCl₄)

(Liquid)

GFW = 237.752

MOLYBDENUM TETRACHLORIDE (MoCl₄)

(LIQUID)

Cl₄Mo

GFW = 237.752

S_{298.15} = [58.682] gibbs/mol

ΔHf_{298.15} = [-110.621 ± 2] kcal/mol

Tm = 590°K

ΔHm* = [4 ± 2] kcal/mol

Tb = [680]*K

ΔHv* = [14.7] kcal/mol

Heat of Formation

The heat of formation is obtained from ΔHf₂₉₈(c) by adding ΔHm* and the difference between H₅₉₀^{*} - H₂₉₈^{*} for crystal and liquid.

Heat Capacity and Entropy

The heat capacities are assumed to be constant at 7 gibbs/g-atom. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

Tm is taken from V. Gutmann, "Halogen Chemistry," Vol. 3, Academic Press, New York, 1967. ΔHm* is estimated such that the derived ΔGf* for MoCl₄(l) yields a reasonable boiling point which is expected to be between 600 and 700°K from comparisons with related compounds.

Vaporization Data

Tb is the temperature at which the Gibbs energy change (ΔGr*) of the following process MoCl₄(l) = MoCl₄(g) approaches zero. The difference between ΔHf* for MoCl₄(l) and MoCl₄(g) at Tb is the heat of vaporization.

TUNGSTEN OXYTETRACHLORIDE (WOCl_4) (CRYSTAL) Cl_4OW
 $\text{OPW} = 341.6614$

$\Delta H^\circ_f = \text{Unknown}$
 $\Delta H^\circ_{298.15} = -150.4 \pm 2 \text{ kcal/mol}$
 $\Delta H^\circ = -10.846 \pm 3 \text{ kcal/mol}$

Heat of Formation.

S. A. Shchukarev, I. V. Vasil'kova and G. I. Novikov¹ measured calorimetrically the heats of reaction (1) and (2) at 298°K as -131.5 ± 0.5 and $-13.6 \pm 0.11 \text{ kcal/mol}$, respectively. The reactions are given as follows:
 (1) $\text{WOCl}_4(\text{c}) + 6 \text{ NaOH}(16.3 \text{ H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(190,000 \text{ H}_2\text{O}) + 4 \text{ NaCl}(50,000 \text{ H}_2\text{O}) + 3 \text{ H}_2\text{O}(1)$
 (2) $\text{H}_2\text{WO}_4(\text{c}) + 2 \text{ NaOH}(16.3 \text{ H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(20,000 \text{ H}_2\text{O}) + 2 \text{ H}_2\text{O}(1)$

Based on these data and the heats of dilution for $\text{NaOH}(\text{aq})^2$, and $\text{Na}_2\text{WO}_4(\text{aq})^3$, we obtain $\Delta H^\circ_{298} = -118.0 \pm 1.6 \text{ kcal/mol}$ for $\text{WOCl}_4(\text{c}) + 40\text{H}^+(\infty\text{H}_2\text{O}) \rightarrow \text{H}_2\text{WO}_4(\text{c}) + 4\text{Cl}^-(\infty\text{H}_2\text{O}) + \text{H}_2\text{O}(1)$. This leads to $\Delta H^\circ_{298}(\text{WOCl}_4, \text{c}) = -160.4 \pm 2 \text{ kcal/mol}$, using $\Delta H^\circ_{298}(\text{H}_2\text{WO}_4, \text{c}) = -270.5 \pm 0.4 \text{ kcal/mol}$ ⁵.

Heat Capacity and Entropy.

$\text{Cp}_{300} = 35.0 \text{ gibbs/mol}$ is estimated using Kopp's rule. Since the melting point of $\text{WOCl}_4(\text{c})$ is approximately 500°K, which is relatively low for oxygen to reach its maximum contribution, we estimate $\text{Cp}_{500} = 40.0 \text{ gibbs/mol}$ based on the values for $\text{WO}_2(\text{c})$, $\text{WO}_3(\text{c})$ and $\text{WCl}_6(\text{c})$.

The entropy, $S^\circ_{298} = 41.3 \text{ eu}$, is calculated from $\Delta S^\circ_{457} = 44.5 \text{ eu}$ for $\text{WOCl}_4(\text{c}) \rightarrow \text{WOCl}_4(\text{g})$ obtained from the second law analysis of the vapor pressure equation given by S. A. Shchukarev and A. V. Suvorov⁴. See $\text{WOCl}_4(\text{g})$ table (Mar. 31, 1967) for details.

It is surprising that this entropy is smaller than the corresponding value for $\text{WOF}_4(\text{c})$. See $\text{WOF}_4(\text{c})$ table (Mar. 31, 1967) for details.

Melting Data.

T_m is calculated as the temperature at which the Gibbs energies of formation of crystal and liquid are equal. The difference between the heats of formation of crystal and liquid at the melting point is ΔH_m . This ΔH_m is derived from 2nd law analyses of the vapor pressure equation determined by Shchukarev and Suvorov⁴. See $\text{WOCl}_4(\text{g})$ tables (Mar. 31, 1967) for details.

TUNGSTEN OXYTETRACHLORIDE (WOCl₄) (LIQUID)

OPW = 341.6614

ΔH_{298.15}^o = -150.711 kcal/mol

ΔH_m^o = 10.646 ± 3 kcal/mol

ΔH_v^o = 10.5 kcal/mol

T_m = 484°K

T_b = 495°K

Heat of Formation.

The heat of formation, ΔH₂₉₈^o(WOCl₄, l) = -150.711 kcal/mol, is calculated from that of the gas by subtracting the heat of vaporization ΔH_v₂₉₈^o = 13.643 kcal/mol. The latter is obtained by the third law method from the vapor pressure equation given by S. A. Shchukarev* and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). Second law analysis gives ΔH_{501.9}^o = 10.32 kcal/mol (ΔH₂₉₈^o = 13.643 kcal/mol) and the boiling point T_b = 493°K. *Earlier data reported by Shchukarev et al., Zh. Neorg. Khim. 1, 357 (1956); 3, 2630(1958); and 5, 1850 (1960), have been revised and they are not used here.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom as suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1959.

The entropy, S₂₉₈^o = 60.6 eu, is calculated from ΔS_{501.9}^o = 20.9 eu for WOCl₄(l) → WOCl₄(g) obtained from the second law analysis of the vapor pressure equation given by Shchukarev and Suvorov, loc. cit.

Melting Data.

See WOCl₄(c) table (Mar. 31, 1967) for details.

Vaporization Data.

T_b is calculated as the temperature at which the Gibbs energies of formation of liquid and gas are equal. The difference between the heats of formation of liquid and gas at the boiling point is ΔH_v^o.

Tungsten Oxytetrachloride (WOCl₄)

(Ideal Gas) GFW = 341.6614

Bond Distance: W-Cl = [2.26] Å W-O = [1.81] Å

Bond Angle: Cl-W-O = Cl-W-Cl = [120°]

Cl-W-Cl = Cl-W-O = [90°]

Cl-W-Cl = [180°]

*Equatorial **Axial

Product of the Moments of Inertia: I_AI_BI_C = [5.873 x 10⁻¹¹²] g³ cm⁶

Heat of Formation

The heat of formation, ΔH_{f,298}(WOCl₄, g) = -137.0 kcal/mol, is calculated from ΔH_{f,298} = 23.4 kcal/mol for WOCl₄(c) → WOCl₄(g). The latter is obtained by the third law method from the vapor pressure equation given by S. A. Shchukarev* and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). Second law analysis gives ΔH_{f,298} = 21.9 kcal/mol (ΔH_{f,298} = 23.4 kcal/mol).

*Earlier data reported by Shchukarev et al., Zh. Neorg. Khim. 1, 357 (1956), 3, 2630 (1956), 5, 1650 (1960), have been revised and they are not used here.

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of SOP₄(g), reported by P. L. Ogggin, H. L. Roberts and L. A. Woodward¹. The bond distance W-O and W-Cl are estimated to be the same as those in WO₃(g) and WOCl₂(g), respectively. The three principal moments of inertia are I_A = 8.260 x 10⁻³⁸, I_B = 1.052 x 10⁻³⁷ and I_C = 6.757 x 10⁻³⁸ g cm².

All vibrational frequencies are estimated by comparison with those observed in the infrared and Raman spectra for SOP₄(g)², WOCl₂(g)³, CrO₂Cl₂(g)^{4,5}, WO₃(g)⁶, and WOCl₆(g)⁶. The frequencies are not listed in point group order.

$\Delta H_f^\circ = -195.7 \pm 1.0$ kcal/mol
 $\Delta H_f^\circ_{298.15} = -194.807 \pm 1.0$ kcal/mol
 $\Delta H_m^\circ = 2.382$ kcal/mol

$S^\circ_{298.15} = 49.93 \pm 0.1$ gibbs/mol
 $T_m = 249.05^\circ\text{K}$

Heat of Formation

The heat of formation, ΔH_f° of TiCl₄(c) is calculated from the corresponding quantity for TiCl₄(l) and the values of $H_{249.05}^\circ - H_{298.15}^\circ$ for both crystal and liquid.

Heat Capacity and Entropy

The heat capacity of TiCl₄(c) has been reported by Latimer (1) and by Furukawa (2). The data from the latter investigation are adopted. These data lead to a value of 44.5 eu for $S_{249.05}^\circ$. This compares with Latimer's value (1) of 43.8 eu for the same quantity. The heat capacity of the solid is extrapolated to a value of 18R at 600°K, based on the known heat capacities of TiBr₄(c) and TiI₄(c). The hypothetical entropy at 298°K is based on the integration of the extrapolated curve and the value at the melting point.

Melting Data

The triple point is reported to be 249.05°K, with a measured heat of fusion of 2.382 kcal/mol, by Furukawa (2). Latimer (1) reported values of 248.0°K and 2.233 kcal/mol for these quantities. The former data are adopted.

Heat of Formation

The heat of formation, ΔH_{f,298,15}^a of TiCl₄(l) is calculated from that of TiCl₄(g) and the value of ΔH_{v,298,15}^d. The value of ΔH_{v,298}^d is determined from second and third law analyses of fugacity as follows.

Source	Method	Range	No. Pts.	2nd Law	3rd Law	Drift, eu	ΔH _f ^e 298

* two points rejected due to failure of a statistical test

** three points rejected due to failure of a statistical test

*** selected points from extensive data

Third law analyses of the several vapor pressure sets result in drifts which are proportional to the mean temperatures. Conversion of these data to fugacity eliminates this temperature dependence and the drifts are then scattered randomly about a constant value. This constant value is made to be essentially zero by methods described on the TiCl₄(g) table. The conversion to fugacity was made using Pitzer's method for normal fluids (5). The calculation was carried out using the value of 45.7 atm for the critical pressure, P_c, reported by Minzer (6) and estimated values of 643 ± 15°K for the critical temperature, T_c, and 0.23 ± 0.03 for the acentric constant, a_c. Schafer et al. (2) reported a calorimetric determination of ΔH_{v,298}^d. Their value of 9.9 ± 0.2 kcal/mol was used to check the reliability of their equipment, assuming that the vapor pressure data (3) gave a more accurate determination of ΔH_{v,298}^d. The adopted value of ΔH_{v,298}^d is 9.82 ± 0.02 kcal/mol.

Heat Capacity and Entropy

The entropy and heat capacity of TiCl₄(l) has been measured by Furukawa (8). His reported values are adopted.

Melting Data

See TiCl₄(c) table for details.

Vaporization Data

The boiling temperature, T_b, is taken as the temperature at which K_p = 1 for the reaction TiCl₄(l) = TiCl₄(g). The vapor pressure data are discussed above.

Bond Distance: Ti-Cl = 2.185 Å

Bond Angle: Cl-Ti-Cl = 109° 28'

Product of the Moments of Inertia: I_AI_BI_C = 4.2092 × 10⁻¹¹² g cm⁶

σ = 12

Heat of Formation

The heat of formation, ΔH₂₉₈^o, of TiCl₄(g) and TiCl₄(l) has been measured by several investigators. The results of these measurements are as follows.

Investigations

Investigations	Method	Reaction	ΔH ₂₉₈ ^o , kcal/mol
Johnson et al. (1959) (1)	Calorimetric	Ti(c)+2Cl ₂ (g) = TiCl ₄ (g)	-192.2
Farber and Darnell (1955) (2)	Equilibrium	TiO ₂ (c)+HCl(g) = TiCl ₄ (g)+2H ₂ O(g)	-192.7
Skinner and Ruehrwein (1955) (3)	Calorimetric	Ti(c)+xCl ₂ (g) = [TiCl ₄ (x-2)C ₂] soln	-190.3±3.0
Gross et al. (1957) (4)	Calorimetric	Ti(c)+xCl ₂ (g) = [TiCl ₄ (x-2)C ₂] soln	-191.5±0.3
Krievie et al. (1956) (5)	Calorimetric	Ti(c)+xCl ₂ (g) = [TiCl ₄ (x-2)C ₂] soln	-190.0±0.4
Thomsen (1982) (6)	Calorimetric	TiCl ₄ (l)+2H ₂ O(l) = 4HCl(0.002 m)+TiO ₂ (c)	-194.5

The chosen value of ΔH₂₉₈^o is that reported by Johnson et al. (1). This investigation has the advantage of being independent of the heat of vaporization of chlorins and any heats of solution in deriving the value of the heat of formation.

Heat Capacity and Entropy

The adopted value for the interatomic distance is that reported by Kimura et al. (7). The tetrahedral structure was established by the Raman work of Bhagavantam (8). The vibrational frequencies determined from the infrared and Raman spectra of TiCl₄ by Hawkins and Carpenter (9) are adjusted downward 8 cm⁻¹ for ν₂ and ν₄ so that the heats of vaporization determined by both second and third law methods are in agreement. See TiCl₄(l) table for details. The principal moments of inertia are: I_A = I_B = I_C = 74.943 × 10⁻³⁹ g cm².

TUNGSTEN TETRACHLORIDE (WCl₄)

(CRYSTAL)

OPW = 325.662

ΔH_f⁰ = UnknownΔH_f⁰_{298.15} = -105.9 ± 15 kcal/molS_{298.15}⁰ = [47.4] gibbs/mol

Td = [771]°K

Heat of Formation.

The heat of formation, ΔH_f⁰₂₉₈(WCl₄, c) = -105.9 kcal/mol, is calculated from ΔH_f⁰₂₉₈ = 58.9 kcal/mol for 3WCl₄(c) = WCl₂(c) + 2WCl₅(g). The value of ΔH_f⁰₂₉₈ is calculated by the third law method from decomposition pressure data in the temperature range from 354°C to 435°C reported by S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The second law ΔH_f⁰₂₉₈ = 73.6 ± 7.9 kcal/mol and the third law drift is -24 ± 12 eu, which would correspond to a total entropy discrepancy of -8 ± 4 eu per mole of WCl₄. This entropy discrepancy is probably within the combined uncertainty of the data and the estimated entropies for the three species. S. A. Shchukarev et al., Vestnik Leningrad. Univ. 14, No. 10, Ser. Fiz. i Khim., No. 2, 78 (1959), have shown that decomposition pressures are essentially independent of the composition in the solid phase until WCl₄(c) is almost completely decomposed to WCl₂(c). This is consistent with the assumption of solid phase activities of unity which we have used in the equilibrium analysis.

Heat Capacity and Entropy.

Cp₂₉₈ = 6.2 gibbs/g-atom and Cp₇₀₀ = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 700°, which is near the decomposition temperature, the heat capacity is obtained by linear interpolation.

The entropy of WCl₄(c), S₂₉₈⁰ = 47.4 eu, is estimated by the method of W. M. Latimer, "Oxidation Potentials," 2nd Ed., Prentice-Hall, Inc., New York, 1952.

Temperature of Decomposition.

Td is calculated as the temperature at which the Gibbs energy change of the reaction 3 WCl₄(c) = WCl₂(c) + 2 WCl₅(g) approaches zero. We have also derived an approximate value of decomposition temperature, Td = 744°K, by extrapolation to one atmosphere total pressure of a log P versus 1/T fit of the decomposition pressure data reported by S. A. Shchukarev et al., Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The difference between the two decomposition temperatures is related to the second law entropy and the adopted entropy.

Bond Distance: W-Cl = [2.26] Å

Bond Angle: Cl-W-Cl = [109.47]°

Product of the Moments of Inertia: I_AI_BI_C = [5.154 x 10⁻¹¹²] g³ cm⁶

Heat of Formation.

The heat of formation, ΔHf°₂₉₈ (WCl₄(g)) = -80.3 kcal/mol, is calculated from ΔHf° = 37.7 kcal/mol for WCl₆(g) → WCl₄(g) + Cl₂(g). The value of ΔHf°₂₉₈ is calculated by the third law method from the equation for log Kp given by S. A. Shchukarev and A. V. Suvorov, *Vestnik Leningrad. Univ.* 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961).

The second law ΔHf°₂₉₈ is 43.6 kcal/mol and the third law drift is -9.6 eu.

Heat Capacity and Entropy.

The molecular configuration is assumed to be tetrahedral similar to those of SiCl₄, TiCl₄, VCl₄, GeCl₄, ZrCl₄, SnCl₄, PbCl₄. The bond distance is estimated to be the same as that in WCl₆(g). The three principal moments of inertia are: I_A = I_B = I_C = 80.18 x 10⁻³⁹ g cm².

All vibrational frequencies are estimated from those of SiCl₄, TiCl₄, VCl₄, GeCl₄, SnCl₄ and PbCl₄ given by Kazuo Nakamoto, "Infrared Spectra of Inorganic and Coordination Compounds," John Wiley & Sons, Inc., New York, 1963.

If it is considered that the metal atoms are effectively ionized, then the W⁴⁺ will have 2 d electrons in a field of chloride ions. The electronic splitting would be roughly the inverse of that in NiCl₂(g), as given by D. W. DeKock and D. M. Gruen, *J. Chem. Phys.* 44, 4387 (1966), where Ni has a d⁸ configuration. By analogy with the splitting in NiCl₂, the low lying electronic levels are estimated to be 10000 cm⁻¹ and 30000 cm⁻¹, both triplets.

ZIRCONIUM TETRACHLORIDE (ZrCl₄)

GTV = 233.032

(CRYSTAL)

Zirconium Tetrachloride (ZrCl₄)

GFW = 233.032

 $\Delta H_f^\circ = 43.36 \pm 0.7$ gibbs/mol $\Delta H_f^\circ = -234.42 \pm 0.26$ kcal/mol $\Delta H_f^\circ = -234.17 \pm 0.26$ kcal/mol $\Delta H_m = 12 \pm 3$ kcal/mol $\Delta H_{298.15}^\circ = 26.4 \pm 0.3$ kcal/mol

Ts = 606.8°K

Heat of Formation

Gal'chenko et al. (1) determined the heat of formation of ZrCl₄(c) by the direct chlorination of the highly pure Zr metal in a bomb calorimeter. Complete chlorination of the metal was accomplished as indicated by the absence of unreacted metal and of lower chlorides. Their value, ΔH_f° (ZrCl₄, c) = -234.17 ± 0.26 kcal/mol, is adopted in the tabulation.

Gross et al. (2) measured calorimetrically $\Delta H_{298}^\circ = -225.69$ kcal/mol for Zr(c) + 2Cl₂(g) = ZrCl₄(c). Corrections for the difference in heat content between liquid and gaseous chlorine at 25°C and 1 atm led to the value of standard heat of formation, ΔH_f° (ZrCl₄, c) = -234.7 ± 0.4 kcal/mol, which is in good agreement with the value adopted. Siemonsen and Siemonsen (3) also measured the heat of formation by direct chlorination of the metal in an enameled bomb calorimeter. However, they did not report their detailed experimental procedure, neither the purity of their sample, nor the corrections. The value was given as $\Delta H_{298}^\circ = -231.9 \pm 0.5$ kcal/mol.

Heat Capacity and Entropy

Todd (4) measured the low temperature heat capacities from 52.6 to 295.7°K, and made an extrapolation to 0°K which yielded an entropy of 8.12 eu at 51°K. We have adopted the measured heat capacities, but have made our own extrapolation to 0°K, based on the ratio of the measured heat capacities of ZrF₄ (5), TiF₄ (6), and TiCl₄ (7) from 6° to 50°K. This extrapolation gives $S_{50}^\circ = 6.758 \pm 0.7$ eu which is used in the table. Coughlin and King (8) measured high temperature enthalpy data from 335.9° to 566.8°K by drop calorimetry. Their data are smoothly joined with Todd's low temperature heat capacities and adopted in the table.

Melting Data

The melting point, 710°K, has been observed by Rahlfs and Fischer (9), Palko et al. (10), Denisova et al. (11, 12).

Palko et al. derived the heat of melting as 9 ± 2.5 kcal/mol from their vapor pressure data. Denisova et al. (11, 12) determined thermographically the heat of melting as 14 ± 3 kcal/mol and also determined the heat of vaporization at 710°K as 10.4 kcal/mol which combined with the heat of sublimation at 710°K (23.6 kcal/mol) gives the heat of melting as 13.4 kcal/mol. A weighted average 12 ± 3 kcal/mol is adopted for the heat of melting.

Heat of Sublimation

Several investigators have measured the vapor pressure of ZrCl₄(c) by the static method. Second and third law analyses for the vapor pressure data are summarized below:

Source	No. of Points	Temperature Range (°K)	ΔH_{298}° (kcal/mol)	Drift (eu)
Rahlfs and Fischer (9)	11	535-607	27.516	46.57
Palko et al. (10)	86*	500-689	26.255	44.573
Denisova et al. (11)	17**	626-708	26.515	44.81
				-0.29±0.51

* 4 points rejected due to failure of a statistical test.

** 1 point rejected due to failure of a statistical test.

The third law value, $\Delta H_{298}^\circ = 26.4$ kcal/mol, is adopted in the tabulation.

The sublimation temperature is obtained from the Gibbs free energy crossover between solid and gas. Rahlfs and Fischer (9) reported the sublimation temperature as 604°K.

Since the sublimation temperature is lower than the melting point, the liquid phase is thermodynamically unstable at normal conditions.

99 (2)	110 (3)

Bond Distance: Zr-Cl = 2.32 ± 0.02 Å

Bond Angle: Cl-Zr-Cl = 109°28'

Product of the Moments of Inertia: I_AI_BI_C = 6.03177 × 10⁻¹¹² g³ cm⁶

σ = 12

Heat of Formation

The heat of formation of gaseous ZrCl₄, ΔH_f²⁹⁸ = -207.77 ± 0.2 kcal/mol, is calculated from the heat of formation of the crystal and the formation derived from vapor pressure data. (See JANAF ZrCl₄(c) table dated Dec. 31, 1969).

Hildenbrand et al. (1) determined the equilibrium constants by the transpiration method for the reaction:

Second and third law analyses for their data are given below:

Series	No. of Points	Temp. Range (°K)	ΔH _f ²⁹⁸ (kcal/mol)	2nd law	3rd law	Drift (eu)	ΔH _f ²⁹⁸ (g)* (kcal/mol)
I	10	1171-1375	28.853	29.321			-205.8
II	9	1169-1374	31.397	30.007		-1.08±0.47	-205.0

*Derived from third law ΔH_f²⁹⁸ and ΔH_f²⁹⁸(ZrO₂, c) = -262.3 kcal/mol, ΔH_f²⁹⁸(HCl, g) = -22.063 kcal/mol and ΔH_f²⁹⁸(H₂O, g) = -57.798 kcal/mol.

The derived heat of formation is in fair agreement with the value adopted.

Heat Capacity and Entropy

Spiridonov et al. (2) measured the bond distance Zr-Cl = 2.32 ± 0.02 Å in the vapor phase by electron diffraction. The molecule was also found to be a regular tetrahedron. The same bond distance was also reported by Lister and Sutton (3) and Kimura et al. (4). The three principal moments of inertia are I_A = I_B = I_C = 84.4942 × 10⁻³⁸ g cm². Wilmshurst (5) observed one fundamental vibrational frequency (ν₃ = 421 cm⁻¹) in the infrared spectrum of ZrCl₄ vapor, and made reasonable estimates (ν₁ = 368, ν₂ = 102 and ν₄ = 112 cm⁻¹) for the three remaining unobserved fundamentals, based on observed overtone and combination bands. Godnev et al. (6) calculated the four fundamental vibrational frequencies (382, 108, 423 and 114 cm⁻¹) from data for related group IV halides through the use of a 5-parameter potential function. Büchler et al. (7) also found in the infrared spectrum the vibrational frequency, ν₃ = 423 cm⁻¹. Delvaule and Francois (8) observed the symmetric stretching vibration ν₁ at 383 cm⁻¹ from the Raman spectrum of ZrCl₄ in PCl₃ and POC₂, both of which form complexes with ZrCl₄. Bobovich (9) reported the symmetric stretching vibration ν₁ at 315 cm⁻¹ from a partially polarized band in his Raman spectrometric studies.

Pontrelli (10) observed in the Raman spectrum all four fundamental vibrational frequencies (376, 99, 418 and 110 cm⁻¹) which are adopted in the tabulation.

$\Delta H_{298.15}^\circ = -126 \pm 2 \text{ kcal/mol}$

$\Delta H_m^\circ = [4.5 \pm 1.5] \text{ kcal/mol}$

$S_{298.15}^\circ = [57 \pm 3] \text{ gibbs/mol}$

$T_m = 467^\circ\text{K}$

Heat of Formation

The heat of formation is obtained from S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin, and A. K. Baev, Zh. Neorg. Khim. 5, 1650 (1960). The authors derived the ΔH_f° (MoCl₅, c) = -126 kcal/mol by measuring the heat of solution of MoCl₅ in NaOH(aq), which was compared with the heats of solution of MoO₃ and NaCl measured in the same solvent.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with that of MoCl₃ (c). S_{298}° is estimated as 57 eu from the vapor pressure data for MoCl₅ (c) + MoCl₅ (g) measured by S. A. Shchukarev, I. V. Vasil'kova and B. N. Sharupin, J. Gen. Chem. USSR (English Transl.) 26, 2335 (1956).

Cl₅Mo

MOLYBDENUM PENTACHLORIDE (MoCl₅) (LIQUID) GFW = 273.205

$$S_{298.15}^{\circ} = [65.441] \text{ gibbs/mol}$$

$$\Delta H_f^{\circ} = [-121.9705] \text{ kcal/mol}$$

$$T_m = 487^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = [4.5 \pm 1.5] \text{ kcal/mol}$$

$$T_b = 537^{\circ}\text{K}$$

$$\Delta H_v^{\circ} = [12.0] \text{ kcal/mol}$$

Heat of Formation

The heat of formation is obtained from $\Delta H_f^{\circ}(c)$ by adding ΔH_m° and the difference between $H_m^{\circ} - H_{298}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed constant and estimated as 42 gibbs/mol or 7 gibbs/g-atm. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

T_m is taken from S. A. Shechukarev, G. I. Novikov, A. V. Suvorov and V. K. Mokeimov, Russ. J. Inorg. Chem. (English Transl.) 4, 935 (1959). ΔH_m° is estimated by comparison with that of WCl₅(c).

Vaporization Data

T_b is the temperature at which the difference between the Gibbs energy of formation for MoCl₅(l) and MoCl₅(g) approaches zero. The difference between $\Delta H_f^{\circ}(\text{MoCl}_5, l)$ and $\Delta H_f^{\circ}(\text{MoCl}_5, g)$ is ΔH_v° .

MOLYBDENUM PENTACHLORIDE (MoCl_5)

(IDEAL GAS)

 $GFW = 273.205$ Point Group D_{3h}
$$\Delta M f_0^\circ = -106.6 \pm 1 \text{ kcal/mol}$$
$$\Delta H_{298.15}^{\circ} = -107.0 \pm 1 \text{ kcal/mol}$$
$$\Delta G_{298.15}^\circ = [95 \pm 3] \text{ gibbs/mol}$$

Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

Meat of Formation

The adopted $\Delta H_f^\circ = -107.0$ Kcal/mol is obtained from the vapor pressure data for $\text{HocCl}_5(\text{c}) \rightleftharpoons \text{HocCl}_5(\text{g})$ measured by Shchukarev et al. (1) and Saeki and Matsuzaki (2).

Source	Method	Reaction	Temperature range, °K	$\Delta H_{298.15}^\circ$	ΔH_{298}°	Drift	ΔH_{298}°
				Second law	Third law	e.u.	kcal/mol
Shchukarev	Transpiration	$\text{MoCl}_5(\text{c}) = \text{MoCl}_5(\text{g})$	343 - 435	19.04 ± 0.45	19.18	0.3	-106.82
Saeki	Manometric	$\text{MoCl}_5(\text{c}) = \text{MoCl}_5(\text{g})$	298 - 474	16.79 ± 0.06	18.94	5.6	-107.06

* Calculation based on third law ΔH_{298}° .

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those of NbCl_5 obtained from infrared and Raman spectra by Carlson (4). Structure, bond distance and bond angle are taken from Evans et al. (4). The three principal moments of inertia are $I_A = I_B = 106.1682 \times 10^{-39}$ and $I_C = 91.0074 \times 10^{-39} \text{ g cm}^2$. The electronic levels are estimated to be 0, 7000 and 14000 cm^{-1} , all doublets, by comparison with those of WCl_6 (5).

PHOSPHORUS PENTACHLORIDE (PCl₅) (IDEAL GAS)

ΔH_f⁰ = -81.0 ± 1.0 kcal. mole⁻¹

Point group D_{3h}

Vibrational Frequencies and Degeneracies

ω, cm. ⁻¹	ω, cm. ⁻¹	ω, cm. ⁻¹
394 (1)	394 (1)	465 (1)
176 (1)	592 (2)	335 (2)
100 (2)	280 (2)	

Bond angles: Cl₂(equatorial)-P-Cl(equatorial) = 120° Cl(axial)-P-Cl(equatorial) = 180° Cl(equatorial)-P-Cl(equatorial) = 90°

Bond distance: P-Cl(equatorial) = 2.04 Å P-Cl(axial) = 2.19 Å

Product of moment of inertia: I_AI_BI_C = 6.3873 X 10⁻¹¹² g.³ cm.⁶

Heat of Formation: σ = 6

ΔH_f⁰ 298.15 was calculated from the ΔH_f⁰ 298.15 for the reaction: PCl₃(g) + Cl₂(g) → PCl₅(g). Third law calculations using experimental equilibrium constants, and free energy functions from JANAF Tables gave a ΔH_f⁰ 298.15 = -20.884 kcal. mole⁻¹. This ΔH_f⁰ is the average of (1) ΔH_f⁰ 298.15 = -20.768 ± 0.26 kcal. mole⁻¹ and (2) ΔH_f⁰ 298.15 = -21.001 ± 0.24 kcal. mole⁻¹. The first, ΔH_f⁰(1), was obtained from eleven experimental equilibrium constants measured by C. Holland, Z. Elektrochem. 18, 234 (1912) as corrected by W. Nernst, Z. Elektrochem. 22, 37 (1916). The second, ΔH_f⁰(2), was obtained from thirteen experimental equilibrium constants measured by W. Fischer and O. Jüßmann, Z. anorg. u. allgem. Chem. 235, 337 (1935).

For the same reaction, PCl₃(g) + Cl₂(g) = PCl₅(g), a third law calculation by D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941) gave a ΔH_f⁰ = -21.320 ± 0.107 kcal. mole⁻¹. With a new assignment of fundamental frequencies J. K. Wilhamurst and H. J. Bernstein, J. Chem. Phys. 27, 661 (1957) reported a ΔS₀⁰ = -20.525 ± 0.16 kcal. mole⁻¹.

The ΔH_f⁰ 298.15 values corresponding to these heats of reaction are:

Source
ΔH _f ⁰ 298.15
-82.9 kcal. mole ⁻¹
-82.1 kcal. mole ⁻¹
-81.9 kcal. mole ⁻¹
D. P. Stevenson and D. M. Yost (loc. cit.).
J. K. Wilhamurst and H. J. Bernstein (loc. cit.).
Calculated using free energy functions from JANAF Tables.

Heat Capacity and Entropy.

The fundamental vibrational frequencies were assigned by Wilhamurst and Bernstein (loc. cit.) from their infrared and Raman spectral data, except the frequency, 176 cm.⁻¹, which they calculated. Electron diffraction data of M. Rouault, Ann. Phys. 14, 78 (1940) and Sargent and Schomaker, (quoted in) J. Chem. Phys. 9, 403 (1941), show the free PCl₅ molecule to be a trigonal bipyramid of D_{3h} symmetry. The bond lengths were calculated from force constants and Badger's rule by Wilhamurst and Bernstein (loc. cit.). Their values are in good agreement with the electron diffraction bond lengths of M. Rouault, (loc. cit.). The calculated moments of inertia are I_A = I_B = 93.2177 X 10⁻³⁹ g. cm.² and I_C = 73.5053 X 10⁻³⁹ g. cm.².

 $\Delta H_f^\circ = \text{Unknown}$ $\Delta H_f^\circ_{298.15} = -122.6 \pm 10 \text{ kcal/mol}$ $\Delta H_m^\circ = 4.917 \pm 1 \text{ kcal/mol}$ $\Delta H_s^\circ_{298.15} = 24.0 \text{ kcal/mol}$ $S^\circ_{298.15} = [52.0] \text{ gibbs/mol}$ $T_m = 526^\circ\text{K}$

Heat of Formation.

The heat of formation, ΔH_f° (WCl₅, c) = -122.6 kcal/mol, is calculated from that of the gas less the heat of sublimation, $\Delta H_s^\circ = 24.0 \text{ kcal/mol}$. The latter is calculated by the third law method from partial pressures of WCl₅(g) derived from the total pressure data* of S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4 Ser. Fiz. i Khim., No. 1, 120 (1959). Dimer pressures, calculated from the same authors' dimer-monomer dissociation data, are subtracted from the total pressures in order to obtain the monomer pressures. Analyses of the monomer pressures over both crystal and liquid give similar results and the average values for ΔH_s° are 20.6 (second law) and 24.0 kcal/mol (third law) with a drift of about 7 eu.

*Earlier data reported by Shchukarev et al., Zhur. Neorg. Khim. 1, 357 (1956); 2, 2630 (1958), have been revised and are not used here.

Heat Capacity and Entropy.

$CP_{298} = 6.2 \text{ gibbs/g-atom}$ and $CP_{526} = 7.25 \text{ gibbs/g-atom}$ are estimated using the method described by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 526°, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, $S^\circ_{298} = 52 \text{ eu}$, is estimated by comparison with those of WCl₂ (c), WCl₄ (c) and WCl₆ (c).

Melting Data.

The melting point was determined from vapor pressure data by Shchukarev et al., loc. cit. The heat of melting is the difference at the melting point between the second law heats of vaporization and sublimation derived from total vapor pressure data of Shchukarev et al., loc. cit.

Heat of Sublimation.

See the heat of formation of WCl₅(g) for details.

Dec. 31, 1962; Dec. 31, 1966

$S^\circ_{298.15} = [59.393] \text{ gibbs/mol}$
 $T_m = 526^\circ\text{K}$
 $T_b = 561.4^\circ\text{K}$

$\Delta H^\circ_{298.15} = -118.4 \text{ kcal/mol}$
 $\Delta H_m^\circ = 4.917 \pm 1 \text{ kcal/mol}$
 $\Delta H_v^\circ = 16.266 \text{ kcal/mol}$

Heat of Formation.

The heat of formation, $\Delta H^\circ_{298}(\text{WCl}_5, l) = -118.4 \text{ kcal/mol}$, is calculated from that of $\text{WCl}_5(c)$ by adding the heat of melting and the difference between $H^\circ_{526} - H^\circ_{298}$ for the crystal and liquid.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom.

The entropy of $\text{WCl}_5(l)$, $S^\circ_{298.15} = 59.393 \text{ eu}$, is calculated in a manner analogous to that of the heat of formation.

Melting Data.

See $\text{WCl}_5(c)$ table for details.

Vaporization Data.

The boiling point, 561.4°K , is calculated as the temperature at which the Gibbs energy of formation for both $\text{WCl}_5(l)$ and $\text{WCl}_5(g)$ are equal. The difference in the heats of formation of $\text{WCl}_5(l)$ and $\text{WCl}_5(g)$ at the boiling point is the heat of vaporization. S. A. Shchukarev, G. I. Novikov and N. V. Andreeva¹ revised their previous data² and derived the boiling point as 561.2°K from their vapor pressure measurements.

* Equatorial ** Axial

Product of the Moments of Inertia: I_AI_BI_C = [9.98 × 10⁻¹¹²] g³ cm⁶

Heat of Formation.

The heat of formation, ΔH°_{f,298} (WCl₅, g) = -98.6 kcal/mol, is calculated from ΔH°_{f,298} = 19.4 kcal/mol for WCl₆(g) → WCl₅(g) + 1/2 Cl₂(g). The value of ΔH°_{f,298} is calculated by the third law method from the equation for log Kp given by S. A. Shchukarev and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). The second law ΔH°_{f,298} is 24.6 kcal/mol and the third law drift is -8.5 eu.

Heat Capacity and Entropy.

The molecular configuration is assumed to be a trigonal bipyramid similar to that of MoCl₅ determined by electron diffraction by R. V. G. Ewens and M. W. Lister, Trans. Faraday Soc. 34, 1358 (1938). The bond distance is estimated to be the same as that in WCl₆(g). The three principal moments of inertia are: I_A = I_B = 105.23 × 10⁻³⁹ and I_C = 90.20 × 10⁻³⁹ g cm².

All vibrational frequencies are estimated from those of SbCl₅, PCl₅, NbCl₅ and TaCl₅ obtained from infrared and Raman spectra by G. L. Carlson, Spectrochim. Acta 19, 1291 (1963).

If it is considered that the metal atoms are effectively ionized, then the W⁵⁺ will have a single d electron in a field of chloride ions. The electronic splitting would be roughly the inverse of that in CuCl₂(g) as given by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966), where Cu has a d⁹ configuration. By analogy with the splitting in CuCl₂, the low lying electronic levels are estimated to be 7000 cm⁻¹ and 14000 cm⁻¹, both doublets.

Molybdenum Hexachloride (MoCl₆)

(Crystal) GFW = 308.658

MOLYBDENUM HEXACHLORIDE (MoCl₆)

(CRYSTAL)

GFW = 308.658

 $\Delta H_f^\circ = \text{unknown}$ $\Delta H_f^\circ_{298.15} = [-125 \pm 10] \text{ kcal/mol}$ $S^\circ_{298.15} = [61.0 \pm 4.0] \text{ gibbs/mol}$ $T_s = [527]^\circ\text{K}$

Heat of Formation

G. I. Novikov and N. V. Galitskii, Zh. Neorg. Khim. 10, 576-8 (1965), assumed that the equilibrium $\text{MoCl}_5(\text{c}) = \text{MoCl}_5(\text{g}) + 1/2 \text{Cl}_2(\text{g})$ exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics, $\Delta H_f^\circ = 4 \text{ kcal/mol}$ and $\Delta S_f^\circ = 8 \text{ eu}$, of the equilibrium $\text{MoCl}_5(\text{c}) = \text{MoCl}_5(\text{c}) + 1/2 \text{Cl}_2(\text{g})$, from which they obtained the $\Delta H_f^\circ_{298}(\text{MoCl}_5, \text{c}) = -125 \text{ kcal/mol}$.

Heat Capacity and Entropy

The adopted heat capacity is the same as that of $\text{WCl}_6(\text{g}, \text{c})$, since the heat capacities of W and Mo are almost the same. The entropy is estimated from that of $\text{MoCl}_5(\text{c})$ by the addition of 4 eu due to one extra chlorine atom in the molecule.

Vaporization Data

The sublimation point is calculated from the free energy crossover between crystal and gas. However, it should be noted that $\text{MoCl}_6(\text{c})$ is unstable with respect to $\text{MoCl}_5(\text{c})$ at all temperatures and thus sublimation could occur only under an atmosphere of Cl_2 .

Heat of Formation

G. I. Novikov and N. V. Galitskii, Zh. Neorg. Khim. **10**, 576-82 (1965), assumed that the equilibrium MoCl₆(g) = MoCl₅(g) + 1/2 Cl₂(g) exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics, $\Delta H_f^\circ = 2.5$ kcal/mol and $\Delta S_f^\circ = 10$ eu of the equilibrium MoCl₆(g) = MoCl₅(g) + 1/2 Cl₂(g), from which they obtained the ΔH_f° (MoCl₆, g) = -105 kcal/mol.

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those of MoF₆ and WF₆, given by K. Nakamoto, "Infrared Spectra of Inorganic and Coordination Compounds," John Wiley and Sons, Inc., New York - London, 1963, and WCl₆ given by J. C. Evans and G. Y. S. Lo, J. Mol. Spectrosc. **25**, 147 (1968).

Structure, bond distance and bond angle are estimated to be the same as those of WCl₆. The three principal moments of inertia are $I_A = I_B = I_C = 120.2684 \times 10^{-39}$ g cm².

TUNGSTEN HEXACHLORIDE, ALPHA (α -WCl₆) (CRYSTAL) GFW = 396.568

$\Delta H_f^\circ =$ Unknown
 $\Delta H_{298.15}^\circ = -141.9 \pm 6$ kcal/mol
 $\Delta H^\circ (a_1 \rightarrow a_2) = [1.0] \text{ kcal/mol}$
 $\Delta H^\circ (a_2 \rightarrow \beta) = 3.77 \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = 23.9 \text{ kcal/mol}$

$S_{298.15}^\circ = [57.0] \text{ gibbs/mol}$
 $Tt (a_1 \rightarrow a_2) = 450 \pm 10^\circ K$
 $Tt (a_2 \rightarrow \beta) = 503^\circ \pm 3^\circ K$

Heat of Formation.

S. A. Shchukarev, I. V. Vasilkova and G. I. Novikov, Zh. Neorg. Khim., **3**, 2642 (1958), have measured calorimetrically the heat of solution of WCl₆(c) and also of H₂NO₄(c) in a 12% solution of NaOH as -188.0 ± 0.3 and -13.6 ± 0.11 kcal/mol, respectively. Based on these data and a heat of dilution value for Na₂WO₄ which is essentially zero, we obtain $\Delta H_{298}^\circ = -174.4 \pm 0.3 \text{ kcal/mol}$ for WCl₆(c) + 6NaOH(16.3H₂O) → H₂WO₄(c) + 6NaCl(22.00H₂O) + 2H₂O(l). This reaction gives $\Delta H_{298}^\circ(WCl_6, c) = -141.9 \pm 6 \text{ kcal/mol}$, using a revised $\Delta H_{298}^\circ(H_2WO_4, c) = -270.5 \text{ kcal/mol}$, and other auxiliary data from JANAP Tables and from V. B. Parker, "Thermal Properties of Aqueous Unit-univalent Electrolytes," NBS-RS-252, Natl. Bur. Std., Washington, D.C., April, 1965. The authors have suggested a possible uncertainty of the order of 5 kcal/mol due to the slowness of the dissolution of WCl₆(c).

Heat Capacity and Entropy.

J. R. Welty¹ has measured the enthalpy changes for WCl₆(a,c) in the temperature range from 406° to 502.4°K by drop calorimetry. Few points were measured in the region of the $a_1 \rightarrow a_2$ transition and no attempt was made to investigate the phase present at the conclusion of the drop. Thus, these data appear to be inadequate to define the heat capacities of the a_1 and a_2 phases. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

The entropy $S_{298}^\circ = 57.0 \text{ eu}$, is calculated from that of the gas using $\Delta S_{298}^\circ = 43.155 \text{ eu}$ from the vaporization and sublimation data given in the WCl₆(g) table (December 31, 1966).

Transition Data.

Transition temperatures and heats of transition have been reported by the following investigators, and their results are summarized as follows:

Investigator	Method	$a_1 \rightarrow a_2$ transition		$a_2 \rightarrow \beta$ transition	
		Temperature (°K)	ΔH° (kcal/mol)	Temperature (°K)	ΔH° (kcal/mol)
Ketelaar ² et al.	Vapor pressure	441	-	500	3.4
Stevenson ³	Cooling curve	458	-	503	-
Welty ¹	Vapor Pressure	-	-	503	1.9
Shchukarev ⁴ et al.	Drop calorimetric	-	-	504	3.4
Dobrotin ⁵	Vapor pressure	-	-	504	3.4
	Approximate calorimetric	-	-	493 ± 10	5.5

The adopted $\Delta H_{450}^\circ (a_1 \rightarrow a_2)$ and $\Delta H_{503}^\circ (a_2 \rightarrow \beta)$ are calculated as 1.0 and 3.77 kcal/mol, respectively, based on the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to a_1 phase as the final state, although no experimental evidence for this is given.

Melting Data.

See WCl₆ (p.c) table (December 31, 1966).

Heat of Sublimation.

See WCl₆(g) table (December 31, 1966) for detailed information about sublimation data.

ΔH°_0 = Unknown
 $\Delta H^\circ_{298.15} = [-136.921] \text{ kcal/mol}$
 $\Delta H^\circ (a_2 \rightarrow \beta) = 3.77 \text{ kcal/mol}$
 $\Delta H^\circ = 1.60 \text{ kcal/mol}$
 $\Delta H^\circ_{298.15} = 18.921 \text{ kcal/mol}$

Heat of Formation.

The heat of formation, $\Delta H^\circ_{298} (\text{WCl}_6, \beta, c) = -136.921 \text{ kcal/mol}$, is calculated from that of $\text{WCl}_6 (g, c)$ by adding the heat of $a_2 \rightarrow \beta$ transition and the difference between $H^\circ_{503} - H^\circ_{298.15}$ for $\text{WCl}_6 (g, c)$ and $\text{WCl}_6 (\beta, c)$.

Heat Capacity and Entropy.

J. R. Welty¹ has measured the enthalpy changes for $\text{WCl}_6 (\beta, c)$ in the temperature range from 508° to 553°K by drop calorimetry. Because of the short temperature range, poor distribution of points, and lack of identification of the phase present at the conclusion of each drop, we feel that the enthalpy data are insufficient to define the heat capacity accurately. The adopted heat capacities are estimated so that they are consistent with the enthalpy data within their probable uncertainty.

The entropy of $\text{WCl}_6 (\beta, c)$, $S^\circ_{298.15} = 67.066 \text{ eu}$, is calculated in a manner analogous to that of the heat of formation.

Transition Data.

See $\text{WCl}_6 (g, c)$ table (Dec. 31, 1966).

Melting Data.

Melting point and heat of melting have been reported by the following investigators, and their results are summarized as follows:

Investigator	Method	Melting Point (°K)	ΔH_m° (kcal/mol)
Ketelaar ² et al.	Vapor pressure	557	2.3
Stevenson ³	Cooling curve	555	-
Welty ¹	Vapor pressure	555	1.5
Shchukarev ⁴ et al.	Drop calorimetric	556	1.6
Dobrotin ⁵ et al.	Vapor pressure	564	2.0
	Approximate calorimetric	545 $\pm$ 12	4.2

The adopted heat of melting, $\Delta H^\circ_{555} = 1.6 \text{ kcal/mol}$, is calculated from the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to a_1 phase as the final state, although no experimental evidence for this is available.

Heat of Sublimation.

$\Delta H^\circ_{298.15}$ is calculated as the difference between $\Delta H^\circ_{298.15}$ for $\text{WCl}_6 (\beta, c)$ and $\text{WCl}_6 (g)$.

TUNGSTEN HEXACHLORIDE (WCl₆)

(LIQUID)

GF_W = 396.568

S_{298.15}^o = [68.085] gibbs/mol

T_m = 555 ± 2 °K

T_b = 613.6 °K

ΔH_f^o_{298.15} = -136.091 kcal/mol

ΔH_m^o = 1.60 kcal/mol

ΔH_v^o = 14.319 kcal/mol

Heat of Formation.

The heat of formation, ΔH_f^o_{298.15}(WCl₆l) = -136.091 kcal/mol, is calculated from that of WCl₆(β,c) by adding the heat of melting and the difference between H_{298.15}^o for WCl₆(β,c) and WCl₆(l).

Heat Capacity and Entropy.

J. R. Welty, Ph.D. Thesis, Oregon State University (1962), has measured the enthalpy changes for WCl₆(l) in the temperature range from 560° to 603°K by drop calorimetry. Since the temperature range was very short and no attempt was made to investigate the phase present at the conclusion of the drop, we feel that the enthalpy data are insufficient to define the heat capacity accurately. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

The entropy of WCl₆(l), S_{298.15}^o = 68.085 eu, is calculated in a manner analogous to that of the heat of formation.

Melting Data.

See WCl₆(β,c) table dated Dec. 31, 1966.

Vaporization Data.

The boiling point, 613.6°K, is calculated as the temperature at which the Gibbs energies of formation for both WCl₆(l) and WCl₆(g) are equal. The difference in the heats of formation of WCl₆(l) and WCl₆(g) at the boiling point is the heat of vaporization.

J. A. A. Ketelaar, G. M. Oosterhout and P. B. Braun, Rec. Trav. Chim. 82, 597 (1943), have determined the boiling point and the heat of vaporization as 603.7°K and 15.24 kcal/mol, respectively, from vapor pressure measurements. S. A. Shchukarev and A. V. Suvorov revised their previous data^{1,3} and gave the boiling point and the heat of vaporization as 616.2°K and 14.7 kcal/mol, respectively, from their vapor pressure measurements.

See WCl₆(g) table, dated Dec. 31, 1966, for detailed information about vaporization data.

Bond Distance: W-Cl = 2.26 Å

Bond Angle: Cl-W-Cl = 90°

Product of the Moments of Inertia: I_AI_BI_C = 1.7396 x 10⁻¹¹¹ g³ cm⁶

σ = 24

Heats of Formation

The heat of formation of WCl₆(g), ΔH_f²⁹⁸ = -118.0 kcal/mol, is calculated from that of the crystal plus the adopted heat of sublimation, ΔH_{sub}²⁹⁸ = 23.9 kcal/mol for WCl₆(s,c). The latter was obtained from third law analysis of the vapor pressure data 1,2,3,4, using all JANAF functions (Dec. 31, 1966).

Investigator	Phase Studied	Temp. range (K)	No. of Points	ΔH _f ²⁹⁸ (kcal/mol)	Drift (eu)	ΔH _f ²⁹⁸ (WCl ₆ /g)***
Stevenson ¹	α, e	462 - 502	38	20.9 ± 0.5	23.74	-118.16
	β*, e	503 - 551	15	23.1 ± 0.2	23.89	-118.01

A. A. Vernon⁴ has also determined the equilibrium constants in the temperature range from 1350° to 1600°K for the decomposition of WCl₆(g) to W(c) and Cl₂(g) by reaction of the sample with a hot tungsten filament in a vacuum bulb. Using the reported equilibrium constants, the heat of formation of WCl₆(g) at 298°K is calculated by the second and third law method as -131.8 ± 2.9 kcal/mol and -135.2 kcal/mol, respectively. The third law drift is 2.4 ± 1.9 au. Unfortunately, the reported equilibrium constants may be seriously in error, since atomic chlorine is the main species at the pressure and temperature studied.

* Enthalpy changes are converted to ΔH_f²⁹⁸ for WCl₆(α, c) → WCl₆(g).

** Vapor pressure equations for the crystal (α,β) and the liquid to gas are given.

*** The third law ΔH_f²⁹⁸ is used in calculation.

Heat Capacity and Entropy

R. O. Evans and W. Lister, Trans. Faraday Soc. 34, 1358 (1938), have determined the octahedral structure for WCl₆(g) by electron diffraction and found the bond length to be 2.26 Å.

The vibrational frequency of ν₃, 375 cm⁻¹, was observed in the infrared spectra by J. C. Evans, The Dow Chemical Company, private communication, Dec. 1, 1966. The values of ν₁, ν₂ and ν₅ (360, 340 and 180 cm⁻¹, respectively) are estimated, based on those of the aqueous ion PtCl₆²⁻ reported by L. A. Woodward and J. A. Creighton, Spectrochim. Acta 17, 594 (1961). The values of ν₄ and ν₆ (140 and 120 cm⁻¹, respectively) are estimated by comparison with those of WF₆(g).

The three principal moments of inertia are I_A = I_B = I_C = 120.2684 x 10⁻³⁹ g cm².

Bond Distance: W-Cl = [2.26] Å

Bond Angle: Cl-W-Cl = [90]° W-Cl-bridge-W = [90]°

Cl-W-Cl = [180]° Cl-W-Cl = [90]°

*Equatorial **Axial

Product of the Moments of Inertia: I_AI_BI_C = [8.638] x 10⁻¹¹⁰ g³ cm⁶

Heat of Formation

The heat of formation, ΔH_f²⁹⁸ (W₂Cl₁₀/g) = -207.6 kcal/mol, is calculated from ΔH_f²⁹⁸ = 10.4 kcal/mol for W₂Cl₁₀(g) = 2 WCl₅(g), using all JANAP Functions (Dec. 31, 1966). The value of ΔH_f²⁹⁸ is obtained from third law analysis of the partial pressures of WCl₅(g) and W₂Cl₁₀(g) derived from PVT data determined by S. A. Shchukarev, G. I. Novikov and N. V. Andreev, Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The second law ΔH_f²⁹⁸ is 10.4 ± 0.3 kcal/mol.

Heat Capacity and Entropy

The molecular configuration is estimated by analogy with that of Mo₂Cl₁₀ reported by D. Z. Sands and P. Zaikin, Acta Cryst. 12, 723 (1959). Chlorine atoms are placed octahedrally around two tungsten atoms and these two octahedra share one common edge with six chlorine and two tungsten atoms in a plane. The bond length is estimated to be the same as that in WCl₆(g). The three principal moments of inertia are I_A = 210.5 x 10⁻³⁹, I_B = 576.8 x 10⁻³⁹ and I_C = 566.8 x 10⁻³⁹ g cm².

All vibrational frequencies are estimated, based on those of WCl₅ (AlCl₃)₂ and Cs₂Cl₂, such that S₂₉₈(W₂Cl₁₀/g) = 216.65 eu. This entropy is derived from ΔS₂₉₈ = 19.92 + 0.5 eu for W₂Cl₁₀(g) = 2WCl₅(g), obtained by second law analysis of the data of Shchukarev et al., loc. cit. The frequencies are not in point group order.

COBALT (Co)

(CRYSTAL)

GFW = 58.9332

 $\Delta H_f^\circ = 0$ kcal/mol $\Delta H_{298.15}^\circ = 0$ kcal/mol $\Delta H_t^\circ = 0.108$ kcal/mol $\Delta H_m^\circ = 3.87 \pm 0.06$ kcal/mol $\Delta H_{298.15}^\circ = 101.5 \pm 0.5$ kcal/mol $S_{298.15}^\circ = 7.18 \pm 0.1$ gibbs/mol $T_t = [700^\circ] \text{ K}$ $T_m = 1768^\circ \text{ K}$

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity of Co(c) is adopted from Hultgren et al. (1). Their selected values are based on the data from nineteen investigations. The entropy values are based on $S_t^\circ = 0.0011$ eu. The heat capacity has a maximum value of 13.14 gibbs/mol at the Curie point (1394°K).

Transition Data

The exact nature of the $\alpha(\text{hcp})-\beta(\text{fcc})$ transition is yet to be clearly elucidated. Three investigations (2,3,4) indicate that it is not a simple time- and temperature-dependent phenomenon. Crystalline cobalt exists as pure β -phase above 700°K whereas mixtures of alpha and beta cobalt commonly coexist in varying proportions below this temperature. The values of T_t° and ΔH_t° are those selected by Hultgren et al. (1).

Melting Data

The temperature and heat of melting are those selected by Hultgren et al. (1).

Heat of Sublimation

The heat of sublimation is calculated from the data of Edwards et al. (5). See Co(g) table for details.

Heat of Formation

The heat of formation (ΔH°_{298}) of Co(l) is obtained from that of the crystal by adding ΔH_m° and the differences between $H_{1768}^\circ - H_{298}^\circ$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity of Co(l) selected by Hultgren et al. (1) is used at temperatures above 1768°K. The heat capacities at temperatures below the melting point are estimated by assuming a glass transition at 1100°K and heat capacities similar to those of the crystal below 1100°K.

Melting Data

See Co(c) table for details.

Vaporization Data

The boiling point is calculated from the adopted thermodynamic functions and the chosen heat of sublimation at 298°K so that the free energy functions calculated by integration of the crystal liquid data and by statistical methods from the gas phase are equal at the boiling point.

Heat of Formation

The heat of formation is the heat of sublimation at 298°K. The adopted value is that reported by Edwards et al. (1). Their value is used because their vapor pressure measurements for Fe (1) and Cu (2) have proved to be very reliable. The results obtained by Vintaikin and Tomash (3) are rejected because their vapor pressure data for Fe (4) resulted in a value for the heat of sublimation which was higher than the accepted value [see JANAF Fe(g) Table for details]. The remaining vapor pressure data are rejected either because the drift was too large or because there were not enough points. Second and third law analyses of the available vapor pressure data gave the following results, with reaction A corresponding to Co(c) = Co(g) and reaction B corresponding to Co(l) = Co(g).

Source	Reaction	Method	No. Pts.	Range, T°K	$\Delta H_f^{\circ} 298.15$	$\Delta H_f^{\circ} 298$

Heat of Formation

The heat of formation, ΔH_f° , is calculated from the equation $\text{Co(g)} = e^- + \text{Co}^+(\text{g})$ with the JANAF auxiliary value for Co(g) ; using an ionization potential of 69438 cm^{-1} (191.377 kcal/mol) obtained from C. E. Moore, "Atomic Energy Levels," Vol. II, U. S. Natl. Bur. Std. Circ. 467, 1949. The value of $H^\circ - H^\circ_{298}$ is -1.504 kcal/mol.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, loc. cit. Levels above $30,000 \text{ cm}^{-1}$ are averaged.

COBALT DIFLUORIDE (CoF₂)

(CRYSTAL)

GFW = 96.9300

Cobalt Difluoride (CoF₂)

(Crystal)

GFW = 96.9300

$$S_{298.15}^{\circ} = 19.60 \pm 0.10 \text{ gibbs/mol}$$

$$T_m = 1400^{\circ}\text{K}$$

$$\Delta H_f^{\circ} = -160.2 \pm 1.0 \text{ kcal/mol}$$

$$\Delta H_f^{\circ}{}_{298.15} = -160.5 \pm 1.0 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 14.058 \pm 3.0 \text{ kcal/mol}$$

$$\Delta H_s^{\circ} = 75.3 \pm 3.0 \text{ kcal/mol}$$

Heat of Formation

Heus and Egan (1) measured the electromotive force of a solid state galvanic cell which involved the reactions

$$E_{973} = 1.611 \text{ volts}$$

$$E_{973} = 2.231 \text{ volts}$$

Combining these results with auxiliary thermodynamic data (2) for the reactants and products, we derive $\Delta H_f^{\circ}(\text{CoF}_2, \text{c}) = -160.2$ and -159.5 kcal/mol .

Several equilibrium studies (3, 4, 5) involving $\text{CoF}_2(\text{c})$ have been reported in the literature. Second and third law analyses of these equilibrium data are summarized below, auxiliary data for Co(c) and $\text{CoCl}_2(\text{c})$ are from (6).

Reference	Chemical Reaction	Temp. Range *K	Points	ΔH_{298}° kcal/mol	2nd law gibbs/mol	3rd law gibbs/mol	Drift $\Delta H_f^{\circ}(\text{CoF}_2, \text{c})$ kcal/mol
(3)	$\text{CoF}_2(\text{c}) + 2\text{HCl(g)} \rightleftharpoons \text{CoCl}_2(\text{c}) + 2\text{HF(g)}$	588-605	3	4.1	1.75±0.4	-1.7±0.1	-162.6±2.0
(4)	$\text{CoF}_2(\text{c}) + \text{H}_2(\text{g}) \rightleftharpoons \text{Co(c)} + 2\text{HF(g)}$	673-673	3	35.2	31.5±1.0	-4.2±3.5	-161.8±2.0
(5)	$\text{CoF}_2(\text{c}) + \text{H}_2\text{O(g)} \rightleftharpoons \text{CoO(c)} + 2\text{HF(g)}$	773-1023	5	30.2	31.1±0.2	0.9±0.3	-160.4±2.0

*Third law values except for the first reaction.

We note that Heus and Egan (1), in the same paper, measured $\Delta H_f^{\circ}(\text{AlF}_3, \text{c}) = -360.2 \text{ kcal}$ in excellent agreement with the JANAF value (2). Domange (5) also measured similar equilibria for MgF_2 and CaF_2 , which were very consistent with the JANAF heats of formation (2). Jellinek and Rudat (4) reported similar equilibria for $\text{PbF}_2(\text{c})$, which show excellent consistency with the JANAF heat of formation (2). Thus, it is apparent that these three sets are probably quite reliable, and we adopt $\Delta H_f^{\circ}{}_{298.15}(\text{CoF}_2, \text{c}) = -160.5 \pm 1 \text{ kcal/mol}$.

Heat Capacity and Entropy

Catalano and Stout (7) measured low temperature heat capacities in the temperature range 10° to 300°K . Heat capacity data above 300°K are calculated from the high temperature (458-1400°K) enthalpy data of Binford et al. (8). Both sets of data were smoothed by computer and joined at 298.15°K .

The value of $S_{298.15}^{\circ}$ is obtained from the low temperature heat capacity data of Catalano and Stout (7) and is based on $S_{10}^{\circ} = 0.013 \text{ gibbs/mol}$.

Melting Data

$T_m = 1400^{\circ}\text{K}$ is from the high temperature enthalpy studies of Binford et al. (8). ΔH_m is calculated from their enthalpy data. Premelting of the sample is assumed to be responsible for the rapid rise in the enthalpy near the melting point. This enthalpy is included in ΔH_m .

Heat of Sublimation

Kana'an et al. (9) made sublimation studies of CoF_2 using Knudsen and Langmuir techniques over the temperature range 972° to 1241°K . Second and third law analyses of these sublimation pressures are summarized below.

Method	Temp. Range *K	No. of Points	ΔH_{298}° kcal/mol	Drift gibbs/mol
Knudsen	1058-1242	17	75.0	0.1±0.2
Langmuir	972-1032	6	72.8	2.6±1.4

The selected value is $\Delta H_{298}^{\circ} = 75.3 \pm 3.0 \text{ kcal/mol}$.

(LIQUID)

COBALT DIFLUORIDE (CoF₂)

GFW = 96.9300

$$S_{298.15}^{\circ} = 20.61 \pm 2.5 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = -152.412 \pm 4.0 \text{ kcal/mol}$$

$$T_m = 1400^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = 14.058 \pm 3.0 \text{ kcal/mol}$$

$$T_b = 12012^{\circ}\text{K}$$

$$\Delta H_v^{\circ} = [48.0] \text{ kcal/mol}$$

Heat of Formation

$\Delta H_f^{\circ}(l)$ is calculated from $\Delta H_f^{\circ}(c)$ by adding the heat of melting and the difference in $(H_{1400}-H_{298})$ between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of liquid CoF₂ is estimated by comparison with those for FeCl₂(l), MgF₂(l), and PbF₂(l) and is assumed constant in the temperature range 298°-3000°K. Binford et al. (1) reported $C_p = 30.3$ gibbs/mol for liquid CoF₂ at 1444°K. This value is based on only two enthalpy points near the melting point and appears high in comparison with heat capacities for other liquid metal dihalides. Therefore, the value is not adopted.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See the CoF₂(c) table for details.

Vaporization Data

T_b is the temperature at which the Gibbs energy change for the process CoF₂(l) + CoF₂(g) approaches zero. The difference between the heat of formation of the gas and liquid at T_b is ΔH_v° .

Bond Distance: Co-F = [1.72] Å

Bond Angle: F-Co-F = [185°]

Product of Moments of Inertia: $I_A I_B I_C = 6.5424 \times 10^{-116} \text{ g cm}^6$ $\sigma = 2$

Heat of Formation

The heat of formation of gaseous CoF₂, $\Delta H_f^\circ = -88.1 \pm 7.0$ kcal/mol, is calculated from the heat of formation of the crystal, $\Delta H_{298}^\circ = -163.4 \pm 4.0$ kcal/mol, and the heat of sublimation, $\Delta H_{298}^\circ = 75.3 \pm 3.0$ kcal/mol. The sublimation value is determined from a third law analysis of the vapor pressure data for CoF₂ reported by Kana'an at al. (1). See CoF₂(c) table for details.

Heat Capacity and Entropy

Büchler et al. (2) investigated the deflection of a molecular beam of CoF₂(g) by an electric field and found that within the sensitivity of the apparatus the molecule was nonpolar and consequently possessed a linear structure. Hastie et al. (3) recently investigated the infrared absorption spectra of several transition metal difluorides through the use of matrix isolation techniques. Isotopic shift measurements for matrix isolated NiF₂, ZnF₂, and CuF₂ in neon and argon indicated that these species were slightly bent. Based upon these results, the authors estimated the F-Co-F angle as 165°. This value is adopted here. The bond length was estimated by Bravar at al. (4). Individual moments of inertia are $I_A = 0.1925 \times 10^{-39}$, $I_B = 18.341 \times 10^{-39}$, and $I_C = 18.533 \times 10^{-39} \text{ g cm}^2$. Hastie et al. (3) isolated CoF₂ in neon and argon matrices and observed the ν_3 fundamental at 762 cm⁻¹. They also calculated $\nu_1 = 600 \text{ cm}^{-1}$ by a valence force field method and estimated ν_2 as 151 cm⁻¹ by applying the variation in the frequencies for the chlorides of Co, Ni, Cu, and Zn to the fluorides. The electronic levels and quantum weights are estimated by comparison with the electronic energy levels for Co²⁺(g) ion (5) and those for CoCl₂(g) observed by Hough et al. (6).

$$T_m = 301.55 \pm 0.01^\circ\text{K}$$

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

Lien (4), Filby (3), and Horgan (5). The adopted values are derived based on the Cp data reported by Filby (3) and Lien (4). Lien measured the heat capacities in the temperature range 0.1874 to 1.20°K in the adiabatic demagnetization cryostat and at higher temperatures, 1.2 to 4.09°K, in the liquid-helium temperature cryostat. The Cs sample was obtained from a commercial source of 99.8 per cent purity. Filby determined the Cp values in the temperature ranges 0.4-1.5°K, 3-26°K and 20-320°K, using commercial samples of 99.9 per cent purity. These two sets of measurements are joined smoothly at 4°K. S_{298.15} is derived from the adopted heat capacities, based on S_{0,20} = 0.0002 eu.

Dauphinee (1) determined the heat capacities of Cs(c) employing a sample badly contaminated with oxygen. In the temperature range of approximately 100 to 200°K, an anomaly of Cp curve somewhat similar to those found for sodium and potassium was reported. This anomaly was not observed by Filby who used the higher purity cesium sample. The Cp values reported by Dauphinee are lower than the adopted ones by about 0.5 to 1.5 per cent in the temperatures 55 to 220°K; above 270°K his reported heat capacities are unreasonably high. Therefore the data are not adopted for evaluation. McCollum (2) calculated the Debye 8 values from the measured low temperature heat capacities and plotted them, since no numerical data were reported these were not used. The low temperature Cp values determined by Martin (3) and Horgan (5) are in good agreement with the adopted ones.

Melting Data

See Cs(4) table for details.

Heat of Sublimation

ΔH_{sub}[°]_{298.15} is calculated as the difference between ΔH_f[°]_{298.15} for Cs(g) and Cs(c).

Heat of Formation

The total pressures of Cs(g) and Cs₂(g) over Cs(c) and Cs(l) in the temperature range 738.6 to 1268.3°K have been measured, using the boiling point method, by Bonilla (4), Tepper (3) and Achener (2); using the static method, by Kröner (10), Scott (7) and Stone (11); and the positive ion method by Taylor (g). Fichtbauer (g) and Hacksbill (g) have determined the vapor pressures of Cs(l) by a spectroscopic method and P-V-T relationships, respectively. Based on the reported total pressures, the partial pressures of Cs(g) and Cs₂(g) are evaluated by use of dimer-monomer ratios calculated from JANAF free energy functions and $\Delta H_{298.15}^\circ = 11.24$ kcal/mol for the reaction $Cs_2(g) = 2Cs(g)$. The value of $\Delta H_{298.15}^\circ$ is adopted such that the derived monomer partial pressures give consistent second and third law heats of vaporization. The results are presented in the table below.

Stone et al. (3) measured the vapor pressures of Cs(l) at temperatures 920-1682°K and pressures 0.811-33.53 atm in both the saturation and superheat regions, using a static method and a refractory metal apparatus with a diaphragm as a null-point detector. These vapor pressures reported at temperatures 920-1267.3°K and total pressure below 10 atm are used for evaluation and are reasonably represented by a mixture of monomer and dimer ideal gases. The value of ΔH_{298}° (Cs, g) is adopted as 18.32±0.5 kcal/mol which is derived based on the vapor pressures reported by Stone et al. The results obtained are in reasonable agreement with the values derived from the other vapor pressure sets.

Investigator	Temperature, °K	Points	No. of ΔH_{298}° , kcal/mol	Drift, eu	ΔH_{298}° , kcal/mol*
1. Stone (1966)	920.6-1267.7	79	18.19±0.02	-0.37±0.02	18.32
2. Achener (1964)	751.5-1144.3	15	18.15±0.04	-0.30±0.05	18.38

5. Wathford (1961)	722.2-1277.8	11	18.01±0.01	0.08±0.01	18.59
6. Taylor (1937)	238.6-298.5	8	18.41±0.03	-0.22±0.11	18.35
	303.3-345.8	6	17.75±0.10	0.32±0.31	18.36
7. Scott (1924)	321.4-386.6	8	17.28±0.28	-0.43±0.79	17.63
8. Fichtbauer (1921)	464.1-505.5	4	17.20±0.74	1.86±1.54	18.60
9. Hacksbill (1913)	503.2-670.2	10	18.33±0.47	-0.56±0.80	18.50
10. Kröner (1913)	522.7-628.7	12	18.67±0.44	-1.00±0.76	18.60

*Calculation based on the third law ΔH_{298}° and $\Delta H_{298}^\circ = 0$ and 0.499 kcal/mol for Cs(c) and Cs(l), respectively.

Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights ($n \leq 10$) are obtained from Moore (11). The electronic levels above 25000 cm⁻¹ are average values calculated from those given by Moore. The missing electronic levels, where quantum number $n = 7, 8, 9$ and 10, and the corresponding quantum weights are estimated according to the method recommended by Gurvich (12). The calculated values at 6000°K, e.g. Cp = 19.668 gibbs/mol and S° = 61.980 eu, are not significantly different from the corresponding values, Cp = 19.650 gibbs/mol and S° = 61.871 eu, obtained from using all the electronic levels reported by Moore for calculation without cutting or adding any levels.

June 30, 1968

Cs⁺

Heat of Formation

The ionization potential of Cs(g) was reported as 3.893 eV or 89.776 kcal/mol by C. E. Moore, U. S. Natl. Bur. Std. Circ. 467, 1958. Based on this data we derived $\Delta H^\circ_{298,15} = 108.1 \pm 1$ kcal/mol for Cs⁺(g).

Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights were reported by Moore, loc. cit. However, the lowest electronic level above ground state is given as 107392.33 cm⁻¹ which is so high that the evaluated thermodynamic properties of Cs⁺(g) will not be affected if we disregard all of these higher levels for calculation. Therefore we do not use them. The H⁻H₂₉₈ value at 0°K is -1.481 kcal/mol.

Electronic Levels and Quantum Weights

$$\frac{E_i, \text{cm}^{-1}}{0} \frac{g_i}{1}$$

Ground State Configuration 1S₀

$$\Delta H^\circ_f = 108.5 \pm 1 \text{ kcal/mol}$$

$$S^\circ_{298,15} = 40.565 \pm 0.0005 \text{ gibbs/mol}$$

$$\Delta H^\circ_{298,15} = 108.1 \pm 1 \text{ kcal/mol}$$

CESIUM FLUORIDE (CsF)

(CRYSTAL)

GFW = 151.9034

 $\Delta H^\circ_f = \text{Unknown}$ $\Delta H^\circ_{298,15} = -132.57 \pm 0.5 \text{ kcal/mol}$ $\Delta H_m^\circ = 5.19 \text{ kcal/mol}$ $\Delta H^\circ_{298,15} (\text{to monomer}) = 47.37 \text{ kcal/mol}$ $S^\circ_{298,15} = [21.1 \pm 2] \text{ gibbs/mol}$ $T_m = 976^\circ\text{K}$

Heat of Formation

The enthalpy of solution (ΔH_{soln}) of CsF(c) in water at 298.15°K has been carefully determined with an adiabatic calorimeter by Somsen (1). Based on the reported value, $\Delta H_{\text{soln},298} = -8.62 \pm 0.04 \text{ kcal/mol}$ and $\Delta H^\circ_{298} = -61.69 (2)$ and -79.5 kcal/mol for Cs⁺ (in H₂O) and F⁻ (in H₂O), respectively, the heat of formation for CsF(c) is calculated to be -132.57 kcal/mol which is adopted.

The value, $\Delta H_{\text{soln},298} = -8.81 \pm 0.2 \text{ kcal/mol}$ for CsF(c), was reported by Parker (1), which is in agreement with the value measured by Somsen (1).

Heat Capacity and Entropy

The heat capacities of CsF(c) are estimated according to the method of Kristov (3), based on $H^\circ_{298} - H^\circ_{298} = 9.4 \text{ kcal/mol}$ reported by Dworin (8). The entropy (S°_{298}) is estimated such that the calculated and observed vapor pressures are in good agreement (see CsF(g) and Cs₂F₂(g) tables for details).

Melting Data

T_m and ΔH_m° are obtained from Bredig (7) and Dworin (8). Bukhalova (9) reported $T_m = 958^\circ\text{K}$, which is not adopted.

Heat of Sublimation

ΔH°_{298} is calculated as the difference between ΔH°_{298} for CsF(g) and CsF(c).

CESIUM FLUORIDE (CsF)

(LIQUID)

GFW = 151.9034

 $S^\circ_{298.15} = [21.534] \text{ gibbs/mol}$ $\Delta H^\circ_{298.15} = -129.983 \text{ kcal/mol}$ $\Delta H_m^\circ = 5.19 \text{ kcal/mol}$ $\Delta H_v^\circ = 27.6 \text{ kcal/mol of liquid}$ $T_m = 976^\circ\text{K}$ $T_b = 1504^\circ\text{K}$

Heat of Formation

 $\Delta H^\circ_{298}(l)$ is obtained from $\Delta H^\circ_{298}(c)$ by adding ΔH_m° and the difference between H°_{298} and the difference between H°_{298} for crystal and liquid.

Heat Capacity and Entropy

Dorbin (1) measured the heat capacity of CsF(l) at the melting point to be 17.7 gibbs/mol which is adopted and assumed to be constant in the temperature range 298 - 3000°K. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See CsF(c) for details.

Vaporization Data

T_b is the temperature at which the calculated vapor pressures of CsF(g) and $\text{Cs}_2\text{F}_2(\text{g})$ equal one atmosphere. The vapor composition at T_m is calculated as CsF 80.3 per cent and Cs_2F_2 19.7 per cent. The heat required to vaporize one mole of liquid to the above vapor mixture at T_m is ΔH_v° .

T_b has been observed as 1524 and 1526°K by Wartenberg (1) and Ruff (2), respectively, which are in fair agreement with the calculated one, 1504°K.

$\omega_e = [280] \text{ cm}^{-1}$ $\sigma = 1$

$B_e = [0.198] \text{ cm}^{-1}$ $\sigma_e = [0.001] \text{ cm}^{-1}$

$r_e = [2.40] \text{ \AA}$

Heat of Formation

The heat of formation is estimated from three calculated values. The methods of estimation are described as follows. Brewer and Margrave (1) suggested that the ΔH_f value for MO(g) from the gaseous ions can be taken as the mean of the corresponding ΔH_f values for the alkali fluoride and chlorides with a maximum uncertainty of 10 kcal/mol. Adopting $\Delta H_f^\circ = -131.1$ and -109.6 kcal/mol for the reaction $\text{Cs}^+(g) + \text{F}^-(g) = \text{CsF}(g)$ and $\text{Cs}^+(g) + \text{Cl}^-(g) = \text{CsCl}(g)$, respectively, we obtain $\Delta H_{298}^\circ = -120.4$ kcal/mol for $\text{Cs}^+(g) + \text{O}^-(g) = \text{CsO}(g)$ which leads to $\Delta H_{298}^\circ(\text{CsO}, g) = 12.0$ kcal/mol. The ΔH_{298}° values of the above species used for calculation are taken from the respective JANAF Thermochemical Tables.

Based on the assumption that $D(\text{Cs-O}) = 1/2[D(\text{Ca}_2) + D(\text{O}_2)]$, we derive $D_{298}(\text{Cs-O}) = 65.2$ kcal/mol and $\Delta H_{298}^\circ = 12.7$ kcal/mol for $\text{CsO}(g)$.

Adopting the Cs-O bond energy as half of the atomization energy of Cs_2O , we calculate $D(\text{Cs-O}) = 60 \pm 10$ kcal/mol and $\Delta H_{298}^\circ(\text{CsO}, g) = 17 \pm 10$ kcal/mol.

The heat of formation for $\text{CsO}(g)$ is tentatively selected as 15 ± 10 kcal/mol.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of the isoelectronic molecule OH(g). ω_e is estimated from those of LiO(g), CaF(g), and CsCl(g). The bond distance is taken from that in CsOH(g) reported by Lide and Kuczkowski (2). ω_e is estimated by comparison with those of the other alkali oxides. The values of B_e and σ_e are calculated from r_e , ω_e and $\omega_e \sigma_e$ by the method suggested by Herzberg (3). The moment of inertia is $1.413 \times 10^{-38} \text{ g cm}^2$.

Heat of Formation

Evidence from the velocity distribution in molecular beams (1) has shown that alkali halide vapors contain significant amounts of polymeric species. Using the same method Eisenstadt (2) determined the molecular composition of CsF vapor in the temperature range 838 - 919°K. Based on the reported equilibrium constants for the reaction (CsF)₂(g) = 2CsF(g), we evaluate the enthalpy change (ΔH_F^o) by the second and third law methods to be 40.53 ± 1.75 and 42.34 ± 0.26 kcal/mol, respectively. Employing ΔH_F^o₂₉₈ = 42.34 and ΔH_F^o₂₉₈(CsF, g) = -85.2 kcal/mol, we obtained ΔH_F^o₂₉₈ = -212.74 kcal/mol for Cs₂F₂(g), which is adopted.

Heat Capacity and Entropy

The Cs₂F₂ molecule is assumed to have a rhombic configuration of symmetry D_{2h} as Cs₂Cl₂(3). The Cs-F bond distance is taken as the same as that in CsF(g). The bond angles and vibrational frequencies are estimated by comparison with those of the other dimeric alkali halides (3, 4). The three principal moments of inertia are: I_A = 1.590 × 10⁻³⁸, I_B = 1.325 × 10⁻³⁷ and I_C = 1.484 × 10⁻³⁷ g cm².

GFW = 281.8094

(IDEAL GAS)

DICESIUM MONOXIDE (Cs₂O) $\Delta H_f^\circ = -20.6 \pm 10$ kcal/mol $\Delta H_f^\circ = -22.0 \pm 10$ kcal/molPoint Group C_{2v} $S_{298.15}^\circ = \{76 \pm 2\}$ gibbs/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

 $\frac{\text{cm}^{-1}}{\text{g cm}^{-1}}$
 [290] (1)
 [130] (1)
 [300] (1)
Bond Distance: Cs-O = $[2.4] \text{ \AA}$ Bond Angle: Cs-O-Cs = $[105^\circ]$ Product of the Moments of Inertia: $I_{AB} I_C = [1.415 \times 10^{-112}] \text{ g cm}^2$

Heat of Formation

The appearance potentials of CsOH and Cs₂O ions were investigated by Emel'yanov et al. (1), using the electron-impact method with a mass spectrometer fitted with a heated ion source and a Pt effusion chamber. The heat of atomization of Cs₂O was derived as 117 ± 9 kcal/mol. Based on this value we calculate the heat of formation (ΔH_f°) of Cs₂O to be -22 ± 10 kcal/mol, employing $\Delta H_f^\circ = 18.68$ and 58.99 kcal/mol for Cs(g) and O(g), respectively. Brewer and Mastick (2) calculated theoretically the stability of gaseous alkali oxides according to ionic models and gave the heats of formation from gaseous atoms for Cs₂O(g) as -74 kcal/mol. The ΔH_f° value is evaluated to be 71.2 kcal/mol which is not adopted.

Heat Capacity and Entropy

The molecular structure of Cs₂O(g) has been determined to be nonlinear by Buchler et al. (3), using electric-deflection method. The Cs-O bond distance is assumed to be the same as that in CsOH(g) reported by Lide and Kuczkowski (4). The bond angle is estimated by comparison with that in the H₂O molecule. Three vibrational frequencies are estimated from those for H₂O(g). The three principal moments of inertia are: $I_A = 5.350 \times 10^{-39}$, $I_B = 1.600 \times 10^{-37}$, and $I_C = 1.6535 \times 10^{-37} \text{ g cm}^2$.

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The low temperature specific heat of copper has been measured by several workers and generally there is good agreement. The selected values lie close to the determinations of J. A. Kok and W. H. Keason (1.2-20°K), Physics 3, 1035 (1936); D. L. Martin (20-300°K), Can. J. Phys. 39, 17 (1960); C. B. Satterthwaite, R. S. Craig and W. E. Wallace, J. Am. Chem. Soc. 76, 232 (1954), and S. M. Dookerby, Can. J. Research 2, 84 (1933) and 15L, 59 (1937). Several other workers have reported values of C_p slightly higher than the adopted values especially W. P. Glaue and P. P. Meads, J. Am. Chem. Soc. 63, 1897 (1941), however these measurements were not used for reasons discussed by Martin. The heat capacity above room temperature has been determined directly by several workers, the values of R. E. Pawel and E. E. Stanbury, J. Phys. Chem. Solids 26, 607 (1965) join well with the low temperature data and are adopted. These values lie within 1% of the values adopted by R. Hultgren, R. L. Orr, P. D. Anderson, and K. K. Kelley "Selected Values of Thermodynamic Properties of Metals and Alloys", John Wiley and Sons, Inc., New York, 1963. Several determinations of the solid enthalpy are also in good agreement with selected heat capacity curve. For references to these determinations refer to Hultgren et al. loc. cit.

Melting Data.

The melting point of copper is well established and the recent determination of W. Heyne, Exptl. Tech. Physik. 12, 87 (1964) is adopted. The heat of fusion was obtained from the calculated enthalpy of the solid at the melting point and the liquid enthalpy measurements of P. Just, A. Meuthen and R. Durrer, Forsch. Geb. Ingenieurw. VDI-Forsch. 204 (1918). The liquid enthalpies of I. B. Fieldhouse, J. C. Hedge, J. I. Lang and T. E. Waterman, ASTIA Doc. No. A. D. 150954 are somewhat higher than the adopted values.

Sublimation Data.

See Cu(g) for details.

Dec. 31, 1965

COPPER (Cu) (LIQUID) AT. WT. = 63.54

$\Delta H_f^\circ = 9.683 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_m^\circ = 1356.6^\circ \text{K.}$
 $\Delta H_v^\circ = 2848^\circ \text{K.}$

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔH_m° and the difference between $H_{1356.6}^\circ - H_{298}^\circ$ for (c) and (l).

Heat Capacity and Entropy.

The heat capacity was calculated from the enthalpy data of P. Kist, A. Weithen and R. Durrer, Forsch. Geb. Ingenieurw. VDI-Forsch. 204 (1916). The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

See crystal table for details.

Vaporization Data.

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

The first eight references may be considered to have reasonable drifts and second and third law agreement. The three Langmuir values are grouped closely together at about 80.3 kcal. mole⁻¹. The Knudsen values all lie a little higher averaging 81.4 kcal. mole⁻¹, the single transport determination is at 80.55 kcal. mole⁻¹. If the evaporation coefficient is not unity in the Langmuir experiments then one would observe lower pressures and higher heats of sublimation, thus it appears that the coefficient must be unity and that all techniques are measuring valid heats of sublimation. A value of 81 ± 0.5 kcal. mole⁻¹ was chosen weighted toward the more precise Knudsen work of Hersh.

Heat Capacity and Entropy.

The electronic ground state configuration and higher electronic levels were taken from C. E. Moore "Atomic Energy Levels", Natl. Bur. Std. Circular 467, Washington 1952.

21928.6	7	72085.4	42
22847.0	5	85388.8	5
23988.3	3	88505.7	9
26264.5	5	95565.7	9

Heat of Formation.

The heat of formation was obtained from the dissociation limit of Cu(g) which was given as 62317.2 cm.⁻¹ (or 178.187 kcal. mole⁻¹) by C. E. Moore "Atomic Energy Levels", Nat. Bur. Stds. Circ. 467, Washington 1952. This value applies to 0°K. the enthalpy of Cu, Cu⁺ and e⁻ between 298°K. and zero are all 1.481 kcal. mole⁻¹, thus at 298°K. the dissociation energy is 179.668 kcal. mole⁻¹. The heat of formation was then obtained from the reaction Cu(g) → Cu⁺ + e⁻ as ΔH_f⁰ 298.15 = 260.668 ± 0.5 kcal. mole⁻¹, the uncertainty is that due to Cu(g).

Heat Capacity and Entropy.

The ground state configuration and higher electronic levels were taken from C. E. Moore, loc. cit. Levels above 100,000 cm.⁻¹ were not included since they do not affect the thermodynamic function, levels above 30,000 cm.⁻¹ were averaged.

COPPER MONOFLUORIDE (CuF)

(CRYSTAL)

GFW = 82.5384

 $\Delta H_f^o = \text{Unknown}$ $\Delta H_f^o_{298.15} = [-46 \pm 10] \text{ kcal/mol}$ $\Delta H_m^o = \text{Unknown}$ $\Delta H_m^o_{298.15} = [58] \text{ kcal/mol}$ $S^o_{298.15} = [15.5 \pm 0.5] \text{ gibbs/mol}$ $T_m = \text{Unknown}$ Heat of Formation

The heat of formation ($\Delta H_f^o_{298.15}$) for CuF(c) is not available from literature at the present time. The lattice energy (U_o) for CuF(c) has been calculated to be 209, 213 and 232 kcal/mol, based on the assumption of ionic bonding in CuF(c), by Pauling, Zachariasen and Ebert and Kottinek, respectively (see T. C. Maddington, Trans. Faraday Soc. 55, 1531 (1959) for details). The corresponding enthalpy change for the reaction CuF(c) = Cu⁺(g) + F⁻(g) was evaluated as 210.18, 214.18 and 233.18 kcal/mol. Using $\Delta H_f^o = 280.67 \text{ kcal/mol}$ for Cu⁺(g) and -62.2 kcal/mol for F⁻(g), the values of ΔH_f^o (CuF, c) were calculated to be -11.7, -15.7 and -34.7 kcal/mol. However, based on $\Delta H_f^o_{298.15}(\text{CuF, g}) = 12 \pm 9 \text{ kcal/mol}$ which was measured, the values of $\Delta H_f^o_{298.15}$ would be 23.7, 27.7 and 46.7 kcal/mol which seem to be too small. By comparison with those for KF(c) and HgF(c), the value of $\Delta H_f^o_{298.15}$ was estimated as 58 kcal/mol. From this $\Delta H_f^o_{298.15}$ value and $\Delta H_f^o_{298.15}(\text{CuF, g})$, the heat of formation for CuF(c) was derived.

Heat Capacity and Entropy

The heat capacities, 298.15-1000°K, and $S^o_{298.15}$ were estimated by comparison with those for CuCl(c), NaCl(c) and NaF(c). The Cp values above 1000°K were obtained by graphical extrapolation.

Heat of Sublimation

The value of $\Delta H^o_{298.15}$ was estimated by comparison with those for KF(c) and HgF(c).

COPPER MONOFLUORIDE (CuF)

(IDEAL GAS)

OFW = 82.5384

Ground State Configuration $1\Sigma^+$
 $\Delta H_f^\circ = 12 \pm 9 \text{ kcal/mol}$
 $S_{298.15}^\circ = 54.11 \text{ gibbs/mol}$
 $\Delta H_f^\circ = 12 \pm 9 \text{ kcal/mol}$
 $\Delta H_f^\circ = 12 \pm 9 \text{ kcal/mol}$

Electronic Levels and Quantum Weights

$$\frac{\epsilon_i, \text{cm}^{-1}}{0} \frac{g_i}{1}$$

$$\omega_e x_e = 3.941 \text{ cm}^{-1}$$

$$\alpha_e = 0.004586 \text{ cm}^{-1}$$

$$r_e = 1.743 \text{ \AA}$$

Heat of Formation

Based on spectroscopic data, the dissociation energy (D_0°) of CuF (g) was selected as $3.0 \pm 1.0 \text{ eV}$ by A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953. Using $\Delta H_f^\circ = 18.36$ and 80.71 kcal/mol for F(g) and Cu(g), respectively, the value of ΔH_f° for CuF (g) was calculated to be $30 \pm 23 \text{ kcal/mol}$.

Values of the dissociation energy for CuF(g) have been derived by R. A. Kent, J. D. McDonald, and J. L. Margrave, J. Phys. Chem. **70**, 874 (1966), as 3.63 ± 0.2 to $4.1 \pm 0.5 \text{ eV}$, based on mass spectrometric studies of CuF₂ sublimation from a Knudsen cell, the appearance potential of CuF⁺ ion from CuF₂ in both reducing and nonreducing systems, and a theoretical calculation assuming an ionic model like that used by E. S. Rittner, J. Chem. Phys. **19**, 1030 (1951). Until further data are available, a value $D(\text{CuF}) = 3.8 \pm 0.5 \text{ eV}$ was recommended. Using this dissociation energy for CuF (g), the heat of formation (298.15°K) for CuF(g) was evaluated to be $12 \pm 9 \text{ kcal/mol}$ which is adopted here.

Heat Capacity and Entropy

The values of ground state configuration, ω_e , $\omega_e x_e$, α_e , r_e , ΔH_f° , $S_{298.15}^\circ$ were obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., New York, 1950, and corrected to the average isotopic species.

CuF₂

(CRYSTAL)

COPPER DIFLUORIDE (CuF₂)

GFW = 101.5368

$\Delta H_f^\circ = \text{Unknown}$
 $\Delta H_f^\circ_{298.15} = -131.2 \pm 0.8 \text{ kcal/mol}$
 $\Delta H_m^\circ = [9.4] \text{ kcal/mol}$
 $\Delta H_f^\circ_{298.15} = 62.5 \pm 0.6 \text{ kcal/mol}$

$S^\circ_{298.15} = [16.4] \text{ gibbs/mol}$
 $T_m = 1043^\circ\text{K}$

Heat of Formation.

The chemical equilibrium for the reaction (1) $\text{CuF}_2(\text{c}) + \text{H}_2(\text{g}) = \text{Cu}(\text{c}) + 2\text{HF}(\text{g})$ has been studied by K. Jellinek and A. Rudat, Z. anorg. allgem. Chem. 175, 281 (1928). The equilibrium gas phase composition was found to be HF 4.3% and H_2 95.7%, at 423°K. From this data the enthalpy change ($\Delta H^\circ_{298.15}$) of the reaction was evaluated. The equilibrium for the reaction (2) $\text{CuF}_2(\text{c}) + \text{H}_2\text{O}(\text{g}) = \text{CuO}(\text{c}) + 2\text{HF}(\text{g})$ was investigated by L. Domange, Compt. rend. 200, 239 (1935). Based on the equilibrium data reported, the $\Delta H^\circ_{298.15}$ value for the reaction was derived. The results obtained are presented as follows.

Reaction	Temperature, °K	Second Law Value	Third Law Value	Drift	$\Delta H^\circ_{298.15}$ kcal/mol
(1)	423	22.38	22.15	—	-152.0
(2)	473.15-723.15	23.06 ± 1.33	22.15	-1.67 ± 1.96	-131.2

Using the third law values for $\Delta H^\circ_{298.15}$, the corresponding $\Delta H^\circ_{298.15}$ (CuF_2 , c) values were calculated. The adopted heat of formation for $\text{CuF}_2(\text{c})$ is $-131.2 \pm 0.8 \text{ kcal/mol}$.

Heat Capacity and Entropy.

The heat capacities, $S^\circ_{298.15}$ and $S^\circ_{298.15}$ were estimated by comparison with those for $\text{CuCl}_2(\text{c})$, $\text{CaF}_2(\text{c})$ and $\text{CaCl}_2(\text{c})$, respectively. The Cp values above 1000°K were obtained by graphical extrapolation.

Melting Data.

T_m was reported by H. M. Haendler, L. H. Towle, E. F. Bennett and M. L. Patterson, Jr., J. Am. Chem. Soc. 76, 2178 (1954). T_m for $\text{CuF}_2(\text{c})$ in $\text{HF}(\text{g})$ or $\text{H}_2(\text{g})$ was found to be $950 \pm 5^\circ\text{C}$ or $785 \pm 10^\circ\text{C}$, respectively, by H. von Wartenberg, Z. anorg. allgem. Chem. 241, 381 (1939). Heat of melting was estimated by comparison with those for other related compounds.

Heat of Sublimation.

See $\text{CuF}_2(\text{g})$ table for details.

OPW = 101.5368

(LIQUID)

COPPER DIFLUORIDE (CuF₂)

$\Delta H_{298.15}^{\circ} = [-124.30] \text{ kcal/mol}$

$\Delta H_m^{\circ} = [9.4] \text{ kcal/mol}$

$\Delta H_v^{\circ} = [43.98] \text{ kcal/mol}$

$S_{298.15}^{\circ} = [20.584] \text{ gibbs/mol}$

$T_m = 1043^{\circ}\text{K}$

$T_b = [1722]^{\circ}\text{K}$

Heat of Formation.

The heat of formation ($\Delta H_{298.15}^{\circ}$) was obtained from $\Delta H_{298.15}^{\circ}$ (CuF₂, c) by adding ΔH_m° and the difference between H_{1043}° - $H_{298.15}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated based on an assumption that the average heat capacity for CuF₂(l) is 7.5 gibbs/atom. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See CuF₂(c) table for details.

Vaporization Data.

T_b is the temperature at which the free energy change for the reaction CuF₂(l) = CuF₂(g) becomes zero. The difference between ΔH_m° for liquid and gas at T_b is ΔH_v° .

Heat of Formation

The vapor pressures of CuF₂(c), at temperatures from 897 to 1026°K, have been determined by R. A. Kent, J. D. McDonald and J. L. Margrave, J. Phys. Chem. 70, 874 (1966). Based on these data, the heat of sublimation (ΔH_{sub}⁰) of CuF₂(c) was derived to be 62.45 ± 0.5 and 62.50 kcal/mol by the second and third law method, respectively. From the values of ΔH_{sub}⁰ and ΔH_f⁰ for CuF₂(c), the heat of formation (ΔH_f⁰) for CuF₂(g) was evaluated.

Heat Capacity and Entropy

The molecular structure, bond distance and angle were estimated by L. Brewer, O. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The ground state electronic configuration, 2Σ⁺, was obtained from A. Büchler, J. L. Stauffer and W. Klemperer, Intern. J. Chem. Phys. 30, 6, Apr. 30, 1964, Arthur D. Little, Inc., Cambridge, Mass. The other electronic levels and quantum weights were assumed from those for CuCl₂(g) reported by J. T. Hougen, G. E. Leroy and T. C. James, J. Chem. Phys. 33, 1670 (1961). The vibrational frequency, ν₃, was determined by P. H. Kasa, E. B. Whipple and M. Weltner, Jr., J. Chem. Phys. 44, 2581 (1966). The other two frequencies, ν₁ and ν₂, were calculated by Valence Force Treatment described by O. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand Company, Inc., New York, 1945, using appropriate force constants. The principal moment of inertia is I = 1.6649 X 10⁻³⁸ g cm².

ΔHf°_{298.15} = -107.64 ± 2.0 kcal/mol

S°_{298.15} = [25.9] gibbs/mol

Td = 433°K

Heat of Formation.

The enthalpy change (ΔHf°₄₃₃) for the reaction Cu(OH)₂(c) = CuO(c) + H₂O(g) has been determined by L. V. Py, Bull. soc. chim. France, No. 3, 545 (1964). Based on the reported value, ΔHf°₄₃₃ = 12 kcal/mol, the heat of formation (ΔHf°_{298.15}) for Cu(OH)₂(c) was derived as -107.64 kcal/mol, using ΔHf°_{298.15} = -37.250 and -57.798 kcal/mol for CuO(c) and H₂O(g), respectively, which was adopted here.

The free energy change (ΔGf°_{298.15}) of the reaction Cu(OH)₂(c) = Cu⁺⁺(aq) + 2 OH⁻(aq) was evaluated to be 26.36 and 26.26 kcal/mol, based on the solubility product for Cu(OH)₂(c) reported by (1) E. S. Oenelina, Zh. prikl. Khim. 37, 1358 (1964) and (2) N. P. Zhuk, Zh. Fiz. Khim. 28, 1523 (1954), respectively. Using values of S°_{298.15} and ΔHf°_{298.15} for Cu⁺⁺(aq) and OH⁻(aq) from "Selective Values of Chemical Thermodynamic Properties," Circular 500, National Bureau of Standards, 1952, and NBS Technical Note 270-1, 1955, by D. D. Wagman and co-workers, the corresponding enthalpy change ΔHf°_{298.15} and heat of formation (ΔHf°_{298.15}) for Cu(OH)₂(c) were derived. The results obtained are presented as follows.

Chemical Reaction	ΔHf° _{298.15} kcal/mol	Reference
Cu(OH) ₂ (c) = Cu ⁺⁺ (aq) + 2 OH ⁻ (aq)	10.06	(1)
Cu(OH) ₂ (c) = Cu ⁺⁺ (aq) + 2 OH ⁻ (aq)	9.97	(2)
CuO(c) + H ₂ O(l) = Cu(OH) ₂ (c)	-1.9	(3)
CuO(c) + H ₂ O(l) = Cu(OH) ₂ (c)	0.3	(4)

The heats of solution of CuO(c) and Cu(OH)₂(c) in HNO₃(aq.) have been determined by (3) de Forcrand, Compt. rend. 157, 441 (1913) to be -16.38 and -14.46 kcal/mol, respectively. From these data the enthalpy change for the reaction CuO(c) + H₂O(l) = Cu(OH)₂(c) was derived as -1.9 kcal/mol. For the same reaction, the enthalpy change was reported to be 0.3 kcal/mol by (4) P. Sabatier, Compt. rend. 125, 301 (1897). Based on ΔHf°_{298.15} = -37.25 and -68.315 kcal/mol for CuO(c) and H₂O(l), respectively, the heat of formation for Cu(OH)₂(c) was evaluated. The results obtained are presented in the above table.

Heat Capacity and Entropy.

The heat capacities, 298.15-700°K, were estimated by comparison with those for CuO(c), CaO(c) and Ca(OH)₂(c). The Cp values above 700°K were obtained by graphical extrapolation. S°_{298.15} was estimated such that the derived ΔGf° (Cu(OH)₂, c) = ΔGf° (CuO, c) + ΔGf° (H₂O, g) at 433°K.

Decomposition Temperature.

Td is the temperature at which the Gibbs energy change for the reaction Cu(OH)₂(c) = CuO(c) + H₂O(g) equals zero.

Heat of Formation.
 The more consistent data relative to the heat of formation are reviewed below. The selected value of -37.25 kcal/mol was derived from $\Delta H^0_{298} = -40.7$ kcal/mol for $Cu_2O(c)$ and $\Delta H^0_{298} = 33.80$ kcal/mol for $2CuO(c) = Cu_2O(c) + O_2$. Four different sets of oxygen dissociation pressure measurements yield heats of reaction in close agreement with each other and with the aqueous calorimetry of Thomsen. Thomsen's data may be reduced to the heat of reduction of $CuO(c)$ by combining heats of reaction for $CuO + H_2SO_4$, $Fe + H_2SO_4$, and $Fe + CuSO_4(aq)$. Direct calorimetric measurement of the heat of reduction by von Wartenberg and Werth yields $\Delta H^0_{298} = -36.04 \pm 0.2$ when corrected for incomplete condensation of water. Direct measurement is difficult and this value may correspond to incomplete reduction. The value of -33.02 reported by Wöhler and Jochum, Z. physik. Chem. 167, 169 (1933), is unreasonable. Equilibrium constants derived from Balesdent and Chiche yield -37.6 kcal/mol by third law analysis, but a serious entropy error is present. This is no doubt due to uncertainties in the activity of Cu in Cu-Au alloys. Other data have been reviewed by Randall, Nielsen and West, Ind. Eng. Chem. 23, 388 (1931).

Heat Capacity and Entropy.

Low temperature values are based on data (15-297°K) from J. Hu and H. L. Johnston, J. Am. Chem. Soc. 75, 2471 (1953). Earlier data from R. W. Miller (71-302°K), J. Am. Chem. Soc. 51, 215 (1929), are in satisfactory agreement, while those of K. Clusius and P. Harteck (30-200°K), Z. physik. Chem. 134, 243 (1928), are higher by several percent. A small anomaly in the heat capacity is observed in the region 210-230°K. Magnetic measurements of M. O'Keefe and F. S. Stone, Phys. Chem. Solids 23, 261 (1962), and neutron diffraction studies of B. N. Brockhouse, Phys. Rev. 94, 781 (1954), suggest that this is a Néel point associated with antiferromagnetism. The entropy was obtained from the heat capacities based on $S^0_{15} = 0.016$ eu.

High temperature values are based on specific heats (373-1273°K) obtained from a dynamic method by D. M. Chizhikov and A. S. Khirik, Tr. Inst. Met. im. A. A. Baikova, Akad. Nauk SSSR, No. 12, 79 (1963); cf. Chem. Abs. 59, 5860 b (1963). Enthalpy data (523-1253°K) of Wöhler and Jochum, loc. cit., lead to a value for S^0_{1200} lower by about 0.25 eu, but this is inconsistent with the equilibrium data for $2CuO = Cu_2O + 0.5 O_2$.

Temperature of Decomposition.

T_d is calculated as the temperature at which ΔF equals zero for $2CuO(c) = Cu_2O(c) + 0.5 O_2(g)$.

Heat of Formation

The heat of formation is calculated from that of the crystal, $\Delta H_{298}^{\circ} = 95.1$ kcal/mol, which was obtained by 3rd law analysis of the sublimation pressure at 1773°K reported by Mack et al. (1). They employed a transpiration method and analysed for copper (in minute amounts) by its catalytic effect on the oxidation rate of sodium sulfite. The resulting pressure is only 100 times the predicted pressure of Cu(g) over CuO(c). These pressures were reported but not used in the range 873-1173°K, since these yield a much smaller value for the heat of vaporization and imply a high dissociation energy.

Some estimates of D_0° CuO obtained by different methods are given below. These estimates along with a correlation of D_0° values for MnO, FeO, NiO and ZnO favor $D_0^{\circ} = 82 \pm 10$, close to the value adopted.

Method	ΔH_{298}° , kcal/mol	D_0° , kcal/mol	ΔH_{298}° , kcal/mol
Mack et al. (1) Transpiration	95.1	80.8	58.9
Arithmetic mean of D_0° for O ₂ and Cu ₂		82	57.7
Geometric mean of D_0° for O ₂ and Cu ₂		73	66.7
Linear Birge-Sponer extrapolation of A ² Π state		76±12	63.7±12

Heat Capacity and Entropy

The visible spectrum of CuO has been extensively investigated, but only very recently has significant progress been made in its analysis. Antic-Jovanovic et al. (2) were able to obtain a vibrational analysis of the major band system by use of ⁶³isotope studies. Shirk and Bass (3) recently reported absorption and fluorescence spectra in inert-gas matrices which allows assignment of the ground state and the first two excited states. They have strong evidence for the lower state of the blue system being the ground state and also for the second system, which corresponds to the red-orange system, originating in the upper state of the blue system. Thus, it is probable that the B state is ²Σ and the X and A states are both ²Π with very similar molecular constants, which serves to confuse the analysis of the spectra. It also appears likely that the 4187Å band analysed by Lagerqvist and Uhler (4) is a ²Π-²Π transition terminating in the ground state; thus we adopt their rotational constants for the X and C states. The vibrational frequencies and anharmonicities for the A and B states were from Antic-Jovanovic (2), as well as the vibrational interval for the ground state. The anharmonicity for the ground state was chosen so as to provide a reasonable Birge-Sponer extrapolation of the dissociation energy. The values of the ω_e were estimated from the Morse potential function relations. The rotational constants were assumed to be nearly constant. The values of the splitting in the electronic levels in the X and A states are from Antic-Jovanovic (2), and are roughly confirmed by Shirk and Bass (3).

The thermodynamic functions were calculated by summing over the individual partition functions for the separate states.

COPPER SULFATE (CuSO₄) (CRYSTAL)

GFW = 159.6016

$$\Delta H_f^\circ = -181.66 \pm 0.2 \text{ kcal/mol}$$

$$\Delta H_f^\circ_{298.15} = -184.03 \pm 0.2 \text{ kcal/mol}$$

$$S^\circ_{298.15} = 26.11 \pm 0.1 \text{ gibbs/mol}$$

$$T_d = 1078^\circ\text{K}$$

Heat of Formation.

The heat of solution ($\Delta H_{298.15}$) of CuO(c) in sulfuric acid to form CuSO₄(c) has been measured by L. H. Adami and E. G. King, U. S. Bur. Mines RI 6617, 1965. From the reported value, $\Delta H_f^\circ = -5.61 \pm 0.09 \text{ kcal/mol}$ for the reaction CuO(c) + H₂SO₄(7.068 H₂O) = CuSO₄(c) + H₂O(l), the heat of formation ($\Delta H_f^\circ_{298.15}$ for CuSO₄(c) was evaluated as -184.03 kcal/mol, using $\Delta H_f^\circ_{298.15} = -37.25$, -209.49 and -68.315 kcal/mol for CuO(c), H₂SO₄(7.068 H₂O) and H₂O(l), respectively. See Fe₂(SO₄)₃(c) table for the sources of the last two $\Delta H_f^\circ_{298.15}$ values.

The equilibrium pressures for the following chemical reactions: (A) 2CuSO₄(c) = CuO·CuSO₄(c) + SO₃(g), (B) 3Cu(c) + CuSO₄(c) = 2Cu₂O(c) + SO₂(g), and (C) 4CuSO₄(c) + Cu₂O(c) = 3CuO·CuSO₄(c) + SO₂(g), were determined by several investigators. For reaction (A), the partial pressures of SO₃(g) at different temperatures were calculated from the measured total pressures exerted by SO₃(g), SO₂(g) and O₂(g) produced by the reaction SO₃(g) = SO₂(g) + 1/2 O₂(g). From these vapor pressure data, the corresponding enthalpy changes ($\Delta H_{298.15}$) for the three reactions were evaluated by the second and third law methods. The results obtained are presented in the following table. The value of $\Delta H_f^\circ_{298.15}$ (CuSO₄, c) adopted was -184.03 ± 0.2 kcal/mol.

Heat Capacity and Entropy.

The low temperature heat capacities, 52.67-296.29°K, were obtained from W. W. Weller, U. S. Bur. Mines RI 6669, 1965. The high temperature heat capacities were measured by H. Schottky, Z. phys. Chem. 54, 415 (1908), 282°K; R. Ewald, Ann. Physik., 44, 1215 (1914), 275-373°K; A. N. Krestovnikov and E. J. Peigine, J. Gen. Chem. USSR, 6, 1481 (1936), 288-873°K; and D. M. Chizhikov and A. S. Khirik, Tr. Inst. Met. Im. A. A. Baikova, Akad. Nauk SSSR, No. 12 79-84 (1963), 373-1273°K. The heat capacities below 51°K were obtained from J. W. Stout, J. Chem. Phys. 2, 285 (1941). In that paper, the Cp values, 15-58°K, were plotted as function of temperature and the Cp curve shows a maximum at 34.8°K. In an attempt to evaluate the entropy due to the anomalous portion of the curve, a "normal" heat capacity curve was drawn. The entropy above the normal Cp curve is reported to be 0.48 eu, rather than a magnetic entropy of Rln2 = 1.377 eu. Apparently the magnetic entropy increases gradually above 40°K so that it is not feasible to separate the heat capacity due to magnetic effects from that of the crystal lattice.

The Cp values above 298.15°K were extrapolated smoothly by comparison with those for MnSO₄(c) (see FeSO₄(c) table for details). The adopted Cp values are close to the average of the reported Cp values.

The value of $S^\circ_{298.15}$ was derived using the low temperature Cp data reported by W. W. Weller, loc. cit., based on $S^\circ_{51} = 2.851$ eu evaluated from Cp data determined by J. W. Stout, loc. cit.

Decomposition Temperature.

T_d is the temperature at which the total pressure of the gaseous decomposition products equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for CuSO₄(c), determined by T. R. Ingraham, loc. cit.

Heat of Formation

The heat of formation was calculated from that of Cu(g) using $\Delta H_f^\circ = 46.0 \text{ kcal/mol}$ for $\text{Cu}_2(\text{g}) \rightarrow 2 \text{ Cu(g)}$ obtained by third law analysis of the mass spectrometric data of Ackerman et al. Earlier studies of mass spectra and of the electronic band spectra yield values in reasonable agreement as shown below. The selected ΔH_f° corresponds to $D_0 = 1.97 \text{ eV}$ compared with the linear Birge-Sponer extrapolation of 2.1 eV.

Source	Method	Range °K	2nd law	3rd law	Drift eu	ΔH_f° kcal/mol
1. Ackerman et al. (1950)	Mass Spect.	1549-1709	47.8 ± 2.6	45.99	-1.0 ± 1.6	116.0
2. Schiessel (1957)	Mass Spect.	1575-1720	50.3 ± 3.7	46.76	-2.1 ± 2.3	115.0

1. M. Ackerman, P. E. Stafford and J. Drowart, J. Chem. Phys. **33**, 1784 (1960). Dimer-monomer pressure ratio obtained from intensity ratio using factor 0.705.

2. P. Schiessel, J. Chem. Phys. **26**, 1276 (1957). Point at 1730°K omitted. Dimer-monomer pressure ratio obtained from intensity ratio using factor 0.598.

3. J. Drowart and R. E. Honig, J. Chem. Phys. **25**, 581 (1956).

4. B. Klemen and S. Lindqvist, Arkiv Fysik **9**, 333 (1954).

Heat Capacity and Entropy

Molecular constants, except for $\omega_e x_e$, were taken from the rotational analysis of bands of the B-X system given by D. N. Travia and R. P. Barrow, Proc. Chem. Soc. (London), **44** (1962). The value for $\omega_e x_e$ was obtained from the earlier study of Klemen and Lindqvist, loc. cit., who showed by means of the vibrational isotope effect that the emitter was Cu_2 . The spectroscopic characters of the ground and excited states are uncertain, but Travia and Barrow indicate that the transition is probably $1\Sigma_u^+ - 1\Sigma_g^+$ for the B-X system. Vibrational and rotational constants were adjusted for 30.91% ^{65}Cu .

Copper Monoxide (Cu₂O)

(Crystal) GFW = 143.0794

Cu₂O

DICOPPER MONOXIDE (Cu₂O) (CRYSTAL) GFW = 143.0794

$\Delta H_f^\circ = -40.31 \text{ kcal/mol}$
 $\Delta H_f^{298.15} = -40.7 \pm 0.5 \text{ kcal/mol}$
 $\Delta H_m^\circ = 13.58 \pm 2 \text{ kcal/mol}$
 $T_m = 1509^\circ\text{K}$

Heat of Formation.

Summarized below are the more consistent results for the heat of formation. The selected value of -40.7 kcal/mol is based on data from Thomsen and from Ishakawa and Kimura. More recent equilibrium data yield essentially the same average for ΔH_f but the separate values scatter by about $\pm 0.7 \text{ kcal/mol}$ and significant entropy errors are apparent. Thomsen obtained values of -40.80, -40.87 and -41.51 from aqueous calorimetry using three different paths. He favored the first path which may be recalculated by combination of the heats of reaction of $\text{Cu}_2\text{O} + \text{H}_2\text{SO}_4$, $\text{Fe} + \text{H}_2\text{SO}_4$ and $\text{Fe} + \text{CuSO}_4(\text{aq})$ to yield the heat of reduction of Cu_2O with H_2 . Direct measurements of the heat of reduction reported by L. Wöhler and N. Jochum, *Z. physik. Chem.* 167A, 169 (1933), appear to be unreliable since they lead to -43.0 for the heat of formation. The cell data of Ishakawa and Kimura show very little drift and are in excellent agreement with Thomsen.

Heat Capacity and Entropy.

Low temperature values are based on data from L. V. Oregon (2.8-21°K), *J. Phys. Chem.* 56, 1645 (1962) and from J. Hu and H. L. Johnston (15-300°K), *J. Am. Chem. Soc.* 73, 4550 (1951). Earlier data by R. W. Miller (76-291°K), *J. Am. Chem. Soc.* 51, 215 (1929) are in satisfactory agreement. The entropy was obtained from the heat capacities based on $S_{2.8}^\circ = 0.0015 \text{ eu}$.

High temperature values were obtained from specific heats (373-1273°K) determined with a dynamic method by D. M. Chizhikov and A. S. Knirik, *Tr. Inst. Met. im A. A. Baikova, Akad. Nauk SSSR*, No. 12, 79 (1963); cf. *Chem. Abs.* 59, 79 (1963). Enthalpy data (543-1223°K) from Wöhler and Jochum, *loc. cit.*, yield for S_{1000}° a value about 0.4 eu higher, but this is inconsistent with extensive equilibrium data for $2\text{Cu}(\text{c}) = \text{Cu}_2\text{O}(\text{c}) + 0.5 \text{O}_2$ (see $\text{CuO}(\text{c})$).

Melting Data.

For details see $\text{Cu}_2\text{O}(\text{l})$.

June 30, 1966

$S_{298.15}^{\circ} = 22.901$ gibbs/mol
 $T_m = 1509^{\circ}\text{K}$

$\Delta H_{298.15}^{\circ} = -32.029$ kcal/mol
 $\Delta H_m^{\circ} = 13.58 \pm 2$ kcal/mol

Heat of Formation.
 The heat of formation was calculated from that of the crystal by adding ΔH_m° and the difference between $(H_{1509}^{\circ} - H_{298}^{\circ})$ for the crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated on the basis of 8 gibbs per g atom, giving a value of 24 gibbs/mol which is essentially the same as that of the crystal at the melting point. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

T_m is the value recommended by S. J. Schneider, NBS Monograph 88, U. S. Govt. Printing Office, Washington, D.C., October, 1963, based on pressure-temperature-composition studies of H. S. Roberts and P. H. Smyth, J. Am. Chem. Soc. 43, 1061 (1921). The heat of melting was selected as 13.58 kcal/mol, corresponding to $\Delta S_m^{\circ} = 3$ eu per g atom. A value of 13.4 kcal/mol has been derived from the Cu₂O-CuCl phase diagram by K. K. Kelley, USNM Bulletin 393, U. S. Govt. Printing Office, Washington, 1936. Another value may be obtained from oxygen dissociation pressures for the system Cu₂O(l)-CuO(c) determined by Roberts and Smyth, loc. cit. Equilibrium constants may be obtained for the reaction $2\text{CuO}(c) = \text{Cu}_2\text{O}(l) + 0.5 \text{O}_2$ by assuming the activity of Cu₂O in the melt to be equal to its mole fraction. Based on the mole fractions given by Randall, Nielsen and West, Ind. Eng. Chem. 23, 388 (1931), the equilibrium data yield $\Delta H_m^{\circ} = 15.8 \pm 0.8$ kcal/mol by second law analysis of all points or 12.9 ± 1.6 by omission of 4 points at high pressure and low mole fraction. These results appear to be consistent with the selected value within the approximations involved.

Copper Oxide Sulfate ($\text{CuO} \cdot \text{CuSO}_4$) (Crystal)

$\Delta H_f^\circ = 239.141$

$$\Delta H_f^\circ = 239.141$$

$$\Delta H_f^\circ = 239.141$$

$$S_{298.15}^\circ = [57.5 \pm 2] \text{ e.u./mol}$$

$$T_0 = 1135.4^\circ\text{K}$$

Heat of Formation.

The equilibrium pressures for the following reactions: (A) $\text{CuO} \cdot \text{CuSO}_4(s) = 2\text{CuO}(c) + \text{SO}_2(g)$ and $\text{SO}_3(g) = \text{SO}_2(g) + \frac{1}{2}\text{O}_2(g)$, and (B) $\text{CuO} \cdot \text{CuSO}_4(s) = \text{Cu}_2\text{O}(c) + \text{SO}_2(g)$, were determined by (1) A. Rindler and P. Schuster, *Z. anorg. allgem. Chem.*, **126**, 35 (1923), and (2) E. B. Williams, *Trans. Am. Soc. Appl. Phys.*, **55** (1955). Using the reported vapor pressures, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

Reference	Reaction	Temperature, $^\circ\text{K}$	Second Law Value	Third Law Value	Unit	$\Delta H_{298.15}^\circ$, kcal/mol
(1)	A	1015 - 1035	43.03 $\pm$ 2.53	52.43	-0.7 $\pm$ 2.4	-221.5
(2)	B	527 - 1027	41.72 $\pm$ 3.42	42.43	0.6 $\pm$ 3.4	-221.7
(2)	A**	298 - 1153	50.52 $\pm$ 0.16	52.67	1.6 $\pm$ 0.2	-221.7

* Based on the third law value for $\Delta H_{298.15}^\circ$.

** Partial pressures were calculated from JANAF values for the SO_2 - SO_3 equilibrium. The value of $\Delta H_{298.15}^\circ$ ($\text{CuO} \cdot \text{CuSO}_4$, c) adopted is -221.7 $\pm$ 0.3 kcal/mol.

Heat Capacity and Entropy.

The heat capacities were calculated as the sum of those for $\text{CuO}(c)$ and $\text{CuSO}_4(c)$. The value of $S_{298.15}^\circ$ was estimated by comparison with those for $\text{CuO}(c)$ and $\text{CuSO}_4(c)$, and adjusted so that, using the derived free energy functions, the second and third law values for $\Delta H_{298.15}^\circ$ agree reasonably.

Decomposition Temperature.

T_d is the temperature at which the total pressure of the gaseous decomposition products of reaction (A) equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for $\text{CuO} \cdot \text{CuSO}_4(c)$, determined by E. B. Williams, loc. cit.

Fluorine, Monatomic (F)

(Ideal Gas) Mol. wt. = 18.9984

$$\Delta H_f^\circ 0 = 18.36 \pm 0.40 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^\circ 298.15 = 18.86 \pm 0.40 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^\circ 298.15 = 37.917 \text{ cal. deg}^{-1} \text{ mole}^{-1}$$

$$S_{298.15}^\circ = 37.917 \text{ cal. deg}^{-1} \text{ mole}^{-1}$$

Dec. 31, 1960; June 30, 1961; Sept. 30, 1965

Heat of Formation.

The dissociation energy (D_0) of fluorine has been discussed by numerous investigators for many years. Until about fifteen years ago, high values of $D_0(F_2)$, about 65 kcal. mole⁻¹, were widely accepted. These values were obtained from extrapolations of the spectroscopic data for the halogens, e.g. $D_0 = 63.3$ kcal. mole⁻¹ was reported by H. V. Martenbergs, O. Sprenger and J. Taylor, *Z. Physik. Chem., Bodenstein-Pentland*, 61 (1931). However, mean-while many indirect determinations as well as estimation have been carried out, which yield appreciably lower values. In 1950 the available data were examined critically by M. O. Evans, E. Warhurst and E. Whittle, *J. Chem. Soc.* 1524 (1950) and shown to support a value, $D_0(F_2) = 37 \pm 8$ kcal. mole⁻¹. The indirect determinations include (1) the thermal conductivity measurements by E. U. Franck and E. Wicke, *Z. Elektrochem.* 55, 643 (1951); (2) the explosion method by K. Fritz, *Disser.*, Göttingen, 1952; (3) estimation by use of the relations between D_0 and the vibrational frequencies by A. Bucken and E. Wicke, *Naturwiss.*, 37, 233 (1950); and (4) spectroscopic data on the dissociation energy of diatomic fluorides. Recently more direct methods have been used to determine $D_0(F_2)$. They gave similar values. The D_0 values reported by the previous investigators have been reviewed by L. Haar and C. W. Beckett, National Bureau of Standards Report 1435 (1952), and E. Wicke and H. Fritz, *Z. Elektrochem.* 57, 9 (1953).

The low bond dissociation energy of $F_2(g)$ has been attributed to the repulsion between the unshared electrons on the bound fluorine atoms by K. S. Pitzer, *J. Am. Chem. Soc.* 70, 2140 (1948), or to the absence in fluorine of strengthening of the bond by hybridization of the p- or d- orbitals as may take place in the higher halogens by R. S. Mulliken, *J. Am. Chem. Soc.* 77, 884 (1955). M. O. Brown, *Trans. Faraday Soc.* 55, 9 (1959) suggests that the observed low D_0 value results from the large energy required to promote the p atoms to the valence state from which the bond may be formed.

The equilibrium pressures for the reaction $F_2(g) \rightarrow 2F(g)$ have been measured by several investigators. Using the reported equilibrium constants, the dissociation energy, $D_{298.15}$, was evaluated by both the second and third law methods. The results obtained are presented as follows.

Temperature, °K.	$D_{298.15}$, kcal. mole ⁻¹			Reference
	2nd Law Value	3rd Law Value		
759 - 1115	36.91 ± 0.41	37.76	1	
810 - 960	36.7 ± 18.2	38.1	2	
723 - 820	41.8 ± 0.2	38.0	3

4. M. Farber, et al. "Study of Rocket Engine Exhaust Products", Thirteenth Quarterly Report, June 1 - Oct. 31, 1964, Westmont Corporation, Pasadena, California.

By use of H_2-F_2 mixture explosion method, $D_0(F_2)$ was reported as 37 ± 2 kcal. mole⁻¹ by E. Wicke and H. Fritz, loc. cit. K. L. Wray and D. F. Hornis, *J. Chem. Phys.* 24, 1271 (1956), using shock wave method, obtained $D_0 = 31.0 \pm 4.3$ kcal. mole⁻¹. The continuous absorption electronic spectrum of $F_2(g)$ and the Raman displacement for the $0 \rightarrow 1$ vibrational transition have been used by A. L. O. Rees, *J. Chem. Phys.* 26, 1567 (1957) to compute the potential energy curve for the repulsive Π_u state dissociating to two normal $F(g)$. This curve is consistent with the value, $D_0 = 37.1 \pm 0.85$ kcal. mole⁻¹. The absorption spectrum of $F_2(g)$ has been observed in the vacuum UV region by R. P. Iczkowski and J. L. Margrave, *J. Chem. Phys.* 30, 403 (1959). From a progression of bands at 8744, the value, $D_0 = 37.5 \pm 2$ kcal. mole⁻¹ is deduced.

The P_2 dissociation energy is selected as 37.72 ± 0.60 kcal. mole⁻¹, yielding $\Delta H_f^\circ 298.15(P, g) = 18.86 \pm 0.40$ kcal. mole⁻¹.

Heat Capacity and Entropy.

The ground state configuration, electronic levels and quantum weights were taken from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

F⁻

FLUORINE UNINEGATIVE ION (F⁻) (IDEAL GAS)

MOL. WT. = 18.99895

Ground State Configuration 1S₀
S°_{298.15} = 34.768 cal. deg.⁻¹ mole⁻¹
ΔH°_f 0 = -81.1 ± .5 kcal/mole
ΔH°_f 298.15 = -62.2 ± .5 kcal/mole

Electronic Levels and Quantum Weight
C₁, cm.⁻¹ g₁
0.00 1

Heat of Formation.

The heat of formation was calculated from the equation: P(g) + e⁻ → F⁻(g) with the JANAP auxiliary value for P(g) using the measured electron affinity = 3.446 e.v. (79.511 kcal/mole) obtained from R. S. Berry and C. W. Reinmann, J. Chem. Phys. 39, 1540 (1963). Other calculated values for the electron affinity are: 3.37 reported by E. Clementi and A. D. McLean, Phys. Rev. 133, A419 (1964); 3.08 e.v. E. Clementi, A. D. McLean, D. L. Raimondi, and M. Yoshimine, 133, A1274 (1964); 3.50 e.v. B. Edlen, J. Chem. Phys. 33, 98 (1960).

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Neon. The electronic levels above 1 X 10⁵ cm.⁻¹ were omitted because their contribution is negligible below 6000°K. The H⁺-H⁺ value at 0°K. is -1.481 kcal/mole.

 $\omega_e X_e = 4138.37$ cm⁻¹ $\sigma = 1$ $B_e = 20.9557$ cm⁻¹ $\alpha_e = 0.798$ cm⁻¹ $r_e = 0.9168$ Å

Heat of Formation

The selected value is obtained from a least squares, simultaneous solution (1) for the heats of formation of HF(g), HF(50 H₂O) and five closely related fluorides. Other results, based on 23 selected observations relating the 7 variables, are as follows in kcal/mol: HF(50 H₂O), -76.78 ± 0.1; NaF(c), -137.52 ± 0.2; BF₃(g), -271.42 ± 0.4; CF₄(g), -221.04 ± 0.3; NF₃(g), -31.43 ± 0.3; and C₂F₄ (polymer), -198.2 ± 0.7. The ± values are approximate estimates of the overall uncertainty including systematic error. Further details of the simultaneous solution are given in (1).

The values given above require the use of certain auxiliary data; e.g., the value for NaF(c) presumes ΔH_f°_{NaCl} = 0.23 ± 0.01 and ΔH_f°_{Na}(= H₂O) = -57.47 ± 0.04 kcal/mol. Use of these auxiliary data leads to ΔH_f°_{298.15} = -79.82 kcal/mol for HF(= H₂O) and F⁻(= H₂O); however, values for HF(n H₂O) should be obtained from that of HF(50 H₂O) by use of [Δ_f(n) - Δ_f(50)] taken from the tables of Parker (2). This procedure should be reliable except in dilute solutions (n > 1000) where the equilibria HF + H⁺ + F⁻ + HF⁺ + HF⁻ yield an overall ΔH of about 3 kcal/mol. Parker (2) used thermodynamic data for these equilibria in order to calculate Δ_f for the dilute solutions, but recent data (3-5) suggest that minor changes in the calculations may be desirable. For this reason the simultaneous solution includes Δ_f(50) = 3184 ± 300 cal/mol (2) as an "observation" rather than as a fixed value. The result of the simultaneous solution is smaller by only 150 cal/mol, suggesting that Δ_f(50) does not contain a major inconsistency.

Heat Capacity and Entropy

The ground state configuration is that deduced from UV spectra by Johns and Barrow (6). The excited state near 85000 cm⁻¹ is omitted since its contribution to the thermodynamic functions is negligible. High-resolution studies of the vibration-rotation spectrum were reported by Hann et al. (7) and subsequently confirmed by others (8, 9). The analysis of Webb and Rao (2) is adopted for this table.

Product of the Moments of Inertia: I.I.I. = [1.2826 × 10⁻¹⁷] g.³ cm.⁶
σ = 1

Hest of Formation.

The value of ΔH_f° 298.15 for $\text{HFO}(\text{g})$ was calculated based on an estimated value for the heat of atomization i.e., $\Delta H_f^\circ = 161.6 \text{ kcal. mole}^{-1}$ for the reaction $\text{HFO}(\text{g}) = \text{H}(\text{g}) + \text{F}(\text{g}) + \text{O}(\text{g})$. The ΔH_f° value was assumed to be the sum of the F-O and H-O bond energies which were obtained from the corresponding bond energies in $\text{F}_2\text{O}(\text{g})$ and $\text{H}_2\text{O}(\text{g})$ molecules.

Heat Capacity and Entropy.

The H-O and F-O bond distances were assumed to be the same as those in the $\text{H}_2\text{O}(\text{g})$ and $\text{F}_2\text{O}(\text{g})$ molecules. The vibrational frequencies and H-O-F bond angle were estimated by comparison with the corresponding values for $\text{H}_2\text{O}(\text{g})$, $\text{F}_2\text{O}(\text{g})$ and $\text{Cl}_2\text{O}(\text{g})$. The three principal moments of inertia are $I_A = 0.1332 \times 10^{-39}$, $I_B = 3.0366 \times 10^{-39}$ and $I_C = 3.1699 \times 10^{-39}$ g. cm.²

Moments of Inertia: $I_A = 0.9784 \times 10^{-39} \text{ g. cm.}^2$ $\sigma = 3$
 $I_B = 5.8578 \times 10^{-39} \text{ g. cm.}^2$ $I_C = 5.8578 \times 10^{-39} \text{ g. cm.}^2$

Heat of Formation. $\Delta H_f^0 298.15$ was estimated in C. B. Henderson and R. S. Scheffee, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data", January, 1960.

Heat Capacity and Entropy. Vibrational levels and multiplicities were found in Henderson and Scheffee, op. cit. Moments of Inertia were calculated using the constants found in C. Newman, J. K. O'Leane, S. R. Polo, and M. K. Wilson, J. Chem. Phys. **25**, 855 (1956).

Heat of Formation

A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Ed., Chapman and Hall, London 1953, gives 32 ± 12 kcal for the heat of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants from G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York 1950. Rotational constants were estimated using equation III, 123 p. 108, G. Herzberg (loc. cit.). Bond length estimated by comparison of the mercurous halides with thallium and cesium halides.

g

ω_e , cm.⁻¹

$\omega_e x_e$, cm.⁻¹

α_e , cm.⁻¹

r_e , Å

σ^-

Heat of Formation.

R. A. Durie and A. G. Gaydon, J. Phys. Chem. **56**, 316 (1952), have obtained the dissociation limit (from the spectra) of IF as 23570 cm.⁻¹. The first excited states of F and I are 404 and 7598 cm.⁻¹ above the ground state respectively. There are two sets of dissociation products possible: $I(^2P_{1/2}) + F(^2P_{3/2})$ or $I(^2P_{3/2}) + F(^2P_{1/2})$. When corrected to the normal atoms, the observed limit gives $D_0(\text{IF}(g))$ 2.87 ± 0.04 e.v. or 66.18 ± 0.9 kcal. mole⁻¹ and 1.98 ± 0.04 e.v. or 45.66 ± 0.9 kcal. mole⁻¹ for dissociation energy respectively. Durie and Gaydon, loc. cit., favored the lower value. However L. Slutsky and S. H. Bauer, J. Am. Chem. Soc. **76**, 270 (1954) have pointed out a numerical error in their calculations, which removes the chief support for the lower value and presented additional evidence favoring the higher value. More weight was given to the higher value which gives ΔH_f^0 238.15 = -22.648 ± 0.9 kcal. mole⁻¹ for the reaction $1/2 I_2(g) + 1/2 F_2(g) = \text{IF}(g)$.

Heat Capacity and Entropy.

All molecular constants were obtained from W. H. Evans, T. R. Munson, and D. D. Wagman, J. Res. Natl. Bur. Standards **55**, 147 (1955) except $r_e = 1.906$ Å was obtained from L. O. Cole and O. W. Elverum Jr., J. Chem. Phys. **20**, 1543 (1952) and ground state configuration was estimated by comparison with that for IFr and ICl from O. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, 1950.

POTASSIUM FLUORIDE (KF)

GFW = 58.1004

(CRYSTAL)

Potassium Fluoride (KF)
(Crystal)

GFW = 58.1004

$$\Delta H_f^\circ = -135.5 \pm 0.1 \text{ kcal/mol}$$

$$\Delta H_{298.15}^\circ = -135.9 \pm 0.1 \text{ kcal/mol}$$

$$\Delta H_m^\circ = 6.50 \text{ kcal/mol}$$

$$\Delta H_{298.15}^\circ = 57.8 \text{ kcal/mol (to monomer)}$$

Heat of Formation

The heat of solution of KF(c) in water has been measured by several investigators. Their results have been converted to ΔH_{∞}° by Farker (5) and listed in the table below. Using $\Delta H_{\infty}^\circ = -4.24$, $\Delta H_{298}^\circ(K^+ \infty H_2O) = -60.32$ (6), and $\Delta H_{298}^\circ(F^- \infty H_2O) = -79.82$ kcal/mol (7), we obtain $\Delta H_{298}^\circ = -135.9 \pm 0.1$ kcal/mol which is adopted.

Investigator	Temperature, °K	Concentration, molality	No. of Determinations	ΔH_{∞}° , kcal/mol

Heat Capacity and Entropy

The low temperature heat capacities, 16-323°K, were measured by Westrum and Pitzer (8). The high temperature enthalpies, 298-530°K and 291-1187°K, were determined by Westrum and Pitzer (8), and Lyashenko (9), respectively. However, the high temperature Cp values derived from both sets appear to be inconsistent with the low temperature Cp values. The heat capacities derived from the enthalpy data of Westrum and Pitzer are too high (3% at 530°K and less at lower temperatures) to be joined smoothly with their low temperature Cp's. The adopted enthalpy at 530°K is about 1.4% lower than the reported value. The heat capacity derived from the enthalpy data of Lyashenko is 2.5% lower than the adopted one at 900°K. The differences are smaller at lower temperatures. At 900°K, the adopted enthalpy is 1.3% higher than the reported value. The adopted heat capacities in the temperature range, 323-2000°K, are estimated by graphical comparison with other alkali fluorides and chlorides, and joined smoothly with the low temperature data at 298°K.

S₂₉₈° is derived based on the adopted low temperature heat capacities.

Melting Data

See the KF(t) table.

Heat of Sublimation

The value of ΔH_{298}° is obtained as the difference between ΔH_{298}° for KF(c) and KF(g).

Potassium Fluoride (KF)

(Liquid) GFW = 58.1004

POTASSIUM FLUORIDE (KF)

(LIQUID)

GFW = 58.1004

$$S_{298.15}^{\circ} = 16.167 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = -132.519 \text{ kcal/mol}$$

$$T_m = 1131^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = 6.50 \text{ kcal/mol}$$

$$T_b = 1790^{\circ}\text{K}$$

$$\Delta H_v^{\circ}(\text{to mixture}) = 33.9 \text{ kcal/mol of liquid}$$

Heat of Formation

The $\Delta H_{298}^{\circ}(t)$ is obtained from $\Delta H_{298}^{\circ}(c)$ by adding ΔH_m° and the difference between H_{1131}° and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those of the alkali fluorides and chlorides, and is assumed to be constant in the temperature range, 298-1000°K. The Cp value, 16 gibbs/mol, derived from the enthalpy data of Lyashenko (12) appears low and is not adopted.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

Tm has been reported as 1119 (1, 2), 1129 (3, 4), 1131 (5, 6), and 1153°K (7). The value 1131°K is adopted. Kelley (8) evaluated the following freezing-point data of binary systems: KF-AlF₃ (9), KF-K₂SO₄ (10), KF-KCl (11), KF-K₂CO₃ (13), and KF-K₂PO₄ (14), and derived the values of ΔH_m° (in kcal/mol) as 5.5, 5.55, 6.51, 7.1, and 7.1 respectively. The best value is recommended as 6.50 kcal/mol. Other reported ΔH_m° values are 6.70 (2) and 6.75 ± 0.1 kcal/mol (12). The value of heat of melting is tentatively adopted as 6.50 kcal/mol.

Vaporization Data

The boiling point (Tb) is calculated to be the temperature at which the partial pressures of KF(g) and K₂F₂(g) equal one atmosphere. The composition of the gaseous mixture in equilibrium with KF(l) at Tb is calculated as K₂F₂ 21.1% and KF 78.9%. The heat required to vaporize one mole of liquid at Tb is evaluated to be 33.9 kcal. The experimental values for the boiling point are 1778°K (1) and 1771°K (15).

$\epsilon_i, \text{cm}^{-1}$	$\frac{g_i}{0}$	$\frac{g_i}{1}$
$\omega_{\text{e}} = 426.04 \text{ cm}^{-1}$	$\omega_{\text{e}} x_{\text{e}} = 2.43 \text{ cm}^{-1}$	$\sigma = 1$
$B_{\text{e}} = 0.27994 \text{ cm}^{-1}$	$\alpha_{\text{e}} = 0.002335 \text{ cm}^{-1}$	$r_{\text{e}} = 2.17155 \text{ \AA}$

Heat of Formation

The total vapor pressures of KF(g) and $K_2F_2(g)$ over KF(c, l) have been determined by many investigators using the boiling point (1, 2, 5), Knudsen-effusion (3), transpiration (4), and torsion-effusion (5) methods. A method of trial and error is employed to select the appropriate values for $\Delta H_{298}^\circ(\text{KF}, \text{c})$ and $\Delta H_{298}^\circ(\text{KF}, \text{l})$ such that by use of these two values and $\Delta H_{298}^\circ = 50 \text{ kcal/mol}$ for the reaction $K_2F_2(g) = 2\text{KF}(g)$ and the Gibbs energy functions for KF(c), KF(l), KF(g), and $K_2F_2(g)$, the calculated total pressures of KF(g) and $K_2F_2(g)$ are consistent with the measured ones. Adopting $\Delta H_{298}^\circ = 57.8$ and $\Delta H_{298}^\circ = 54.42 \text{ kcal/mol}$, we evaluate the partial pressures of KF(g) and $K_2F_2(g)$ from the reported total pressure measurements. Based on the derived partial pressures for KF(g), the enthalpy changes for the processes: A. KF(c) = KF(g), and B. KF(l) = KF(g) are calculated by the second and third law methods. Using the third law $\Delta H_{298}^\circ = -135.90$ and $-132.519 \text{ kcal/mol}$ for KF(c) and KF(l), respectively, we obtain the ΔH_{298}° for KF(g). The results are presented in the table below.

The dissociation energy (D_0) of KF(g) has been determined as $117 \pm 8 \text{ kcal/mol}$ by flame photometry by Page and Sugden (2), and Bulwicz, Phillips, and Sugden (5), yielding $\Delta H_{298}^\circ(\text{KF}, \text{g}) = -77.6 \pm 8 \text{ kcal/mol}$. Barrow and Caunt (3) measured the fluctuation bands in the ultraviolet absorption spectra of KF and reported the upper limit for the $D_0(\text{KF}, \text{g})$ value to be 121.8 kcal/mol which leads to $\Delta H_{298}^\circ(\text{KF}, \text{g}) = -81.4 \text{ kcal/mol}$ as the lower limit. Gaydon (12) reported $D_0 = 116.9 \pm 4.6 \text{ kcal/mol}$ for KF(g). The corresponding value of ΔH_{298}° is calculated as $-77.5 \pm 4.6 \text{ kcal/mol}$.

The heat of formation for KF(g) at 298°K is adopted as $-78.1 \pm 0.5 \text{ kcal/mol}$.

** Only the data point at 1233°K is adopted for evaluation.

Heat Capacity and Entropy

The rotational transition spectrum of KF(g) has been measured in the millimeter- and submillimeter-wave region with a high resolution molecular-beam absorption spectrometer by Veasey and Gordy (13). From the derived potential constants the vibrational constants were calculated. The reported values for ω_{e} , $\omega_{\text{e}} x_{\text{e}}$, B_{e} , α_{e} and r_{e} are adopted.

Other values of ω_{e} reported are (in cm^{-1}): 390 ± 39 (11), 408 ± 25 (12), 426 ± 4 (13). The value of $\omega_{\text{e}} x_{\text{e}}$ has been determined as 1.45 cm^{-1} by Barrow and Caunt (3), and 2.4 cm^{-1} by Ritchie and Lew (12) and Baikov and Vasilevskii (13). Using the molecular beam electric resonance method, Green and Lew (14) measured the rotational transitions between the $J = 0$ and $J = 1$ states of K_2F_2 and reported the following values: $B_{\text{e}} = 0.27994 \text{ cm}^{-1}$, $\alpha_{\text{e}} = 0.002335 \text{ cm}^{-1}$, and $r_{\text{e}} = 2.17144 \pm 0.00005 \text{ \AA}$ which are in excellent agreement with the adopted values. By use of the same method, Grabner and Hughes (15) investigated the rotational Stark spectrum of K_2F_2 and reported the K-F bond distance for the zeroth vibrational state as $2.55 \pm 0.06 \text{ \AA}$.

Heat of Formation

The $\Delta H_f^{\circ}(\text{LiF})$ is obtained from $\Delta H_f^{\circ}(\text{LiF})$ by adding ΔH_m° and the difference between $H_{1121.3}^{\circ}$ and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

T. B. Douglas and J. L. Dever, J. Am. Chem. Soc. **76**, 4876 (1954), and N. K. Voskresenskaya, V. A. Sokolov, E. I. Banashek, and N. E. Shmidt, Akad. Nauk SSSR, Izvest. Sekt. Fiz. - Khim. Anal. **27**, 733 (1956), have measured the enthalpies of LiF liquid to 1200 and 1400°K, respectively. Using the reported enthalpy data, a constant heat capacity is derived for each set. The adopted C_p for LiF(l) is the mean of the two derived heat capacities, and is extended arbitrarily to the temperatures above T_b and below T_m . The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point has been determined by many investigators. See the table below for details. The adopted value, 1121.3 $\pm$ 1.0°K, is that reported by Douglas and Dever, loc. cit. The heat of melting is the mean of the ΔH_m° values reported by Douglas and Dever, loc. cit., and Voskresenskaya et al., loc. cit.

Vaporization Data

T_b is the temperature at which the partial pressures of LiF(g), $\text{Li}_2\text{F}_2(\text{g})$, and $\text{Li}_3\text{F}_3(\text{g})$, in equilibrium with LiF(l), equal one atmosphere. The vapor composition at the boiling point is evaluated as LiF 69%, Li_2F_2 26.6%, and Li_3F_3 4.44%. The heat required to vaporize one mole of liquid to form 0.739 mole of vapor mixture of the above composition at T_b is calculated to be 35.08 kcal.

The value of T_b for LiF(l) has been reported to be 1943 and 1949°K by O. Ruff, G. Schmidt, and S. Muggan, Z. Anorg. Allgem. Chem. **223**, 83 (1922), and H. von Wartenberg and H. Schulz, loc. cit., respectively, which were obtained by extrapolation of their vapor pressure data, measured by the boiling point method.

Heat of Formation

The molecular species produced on vaporization of lithium fluoride have been studied by many investigators during the last ten years. The occurrence of dimer and trimer molecules in addition to the monomer has been established by use of mass spectro-metric (2, 3, 8), torsion effusion (3, 6), molecular beam (9, 10), and transpiration (11) methods. To evaluate ΔH_F⁰(LiF, g), we have used a trial and error variation of ΔH_F⁰ and ΔH_F⁰ for the monomer, dimer and trimer in order to obtain reasonable agreement with the observed total pressures, 997-1939 K. (3, 2, 3, 5, 6). Using, as guidelines, these total pressures and the equilibrium data for dimer and trimer (see these tables), we adopt ΔH_F⁰(g) = 66.0, 69.57 and 79.73 and ΔH_F⁰(g) = 61.63, 60.83 and 66.62 kcal/mol for LiF, Li₂F₂ and Li₃F₃, respectively. The adopted value ΔH_F⁰(g) = 63.1 kcal/mol is in agreement with the reported values: 64.8 ± 2 (12), 63.6 ± 1 (6) and 63.0 ± 1.5 kcal/mol (8) at 1000 K.

A second and third law analysis of the total pressure data is given below. Monomer pressures for this analysis are obtained by deducing dimer and trimer pressures calculated from JANAF free energy functions and the adopted values of ΔH_F⁰(g) and ΔH_F⁰(g).

The vapor pressure data reported by Eisenstadt et al. (3, 10) are too low and so not consistent with the others and are not used for evaluation. The transpiration data of Sense and Stone (11) and Knudsen-effusion data of Evseev et al. (13) are not considered for analysis because of the complications involved in converting the reported apparent pressures to the real total pressures of the gaseous mixtures containing monomer, dimer and trimer.

Herzberg (14) and Gaydon (15) reported the dissociation energies (D₀) of LiF(g) to be ≤ 6.6 and 5.95 ± 0.3 eV, respectively. Using these D₀ values, we derive ΔH_F⁰(LiF, g) = -95.9 and -80.9 ± 6.9 kcal/mol. By use of flame-photometric method, Page and Sugden (16) and Bulevich et al. (17) gave D₀ = 141 and 136 ± 8 kcal/mol, yielding ΔH_F⁰(LiF, g) = -84.7 and -79.7 ± 8 kcal/mol.

* Data points are calculated from the given vapor pressure equation.

† Process I: LiF(c) = LiF(g); II: LiF(c) = LiF(g); ΔH_F⁰(LiF, g) values are calculated based on the third law ΔH_F⁰(g).

Heat Capacity and Entropy

The infrared spectrum of LiF(g) and microwave spectrum of Li₂F₂ have been observed by Vidale (18), and Wharten and Klemperer (21), respectively. The reported vibrational and rotational constants for Li₂F₂(g) and Li₂F₂(g), are adopted and corrected to the average isotopic species. Veasey and Gordy (19) measured the rotational transitions of Li₂F₂ with a high resolution molecular-beam absorption spectrometer. By use of the electric resonance method of molecular beam spectroscopy, Braunstein and Trischka (22) observed the transitions between v = 0 and v = 1 vibrational states. The infrared spectrum of LiF(g) have also been measured by Vasilievskii and Baikov (20).

Bond Distances: Li-O = [1.59] Å P-O = [1.41] Å

Bond Angle: P-O-Li = [104]°

σ = 1

Product of the Moments of Inertia: I_AI_BI_C = [4.21684 X 10⁻¹¹⁶] g.³ cm.⁶

Heat of Formation.

The heat of formation (ΔH_f⁰ 298.15) for LiFO(g) was calculated from ΔH_f⁰ 298.15 = 139 kcal. mole⁻¹ for the reaction LiFO(g) = Li(g) + F(g) + O(g) where the value of ΔH_f⁰ 298.15 was estimated to be the sum of the P-O and Li-O bond energies. The values of the P-O and Li-O bond energies were obtained from those in P₂O(g) and Li₂O(g) molecules, respectively.

Heat Capacity and Entropy.

The P-O and Li-O bond distances were assumed to be the same as those in P₂O(g) and Li₂O(g) molecules, respectively. The P-O-Li bond angle and vibrational frequencies were estimated by comparison with the corresponding values for the same oxide molecules. The three principal moments of inertia are: I_A = 5.1543 X 10⁻³⁵, I_B = 1.2729 X 10⁻³⁵ and I_C = 6.4272 X 10⁻³⁵ g. cm.²

$$a_e = [0.00386] \text{ cm}^{-1}$$

Heat of Formation

The equilibrium constants for the decomposition of MgF(g) into Mg(g), MgF₂(c) and MgF₂(g) were determined by T. C. Ehlert, Ph.D. Thesis, University of Wisconsin, 1963. Using this data, the heats of decomposition are evaluated by both the third and second law methods. The results are presented in the table below. The equilibrium constants for the reaction $\text{AlF}_3(\text{g}) + 2\text{Mg}(\text{g}) \rightarrow \text{AlF}(\text{g}) + 2\text{MgF}(\text{g})$ were also reported by T. C. Ehlert, loc. cit. The heat of reaction is calculated by the third and second law methods, respectively. The dissociation energy (D_0^o) of MgF(g) was reported to be 3.2 ± 0.7 and 4.2 eu by A. O. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953, and G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., 1950, respectively. The corresponding values of $\Delta H_f^{298.15}$ for MgF(g) are derived. The results are also listed in the table. The value of $\Delta H_f^{298.15}$ for MgF(g) adopted is the average of the first two $\Delta H_f^{298.15}$ values.

Investigator	Chemical Reaction	Third Law Value	Second Law Value	$\Delta H_f^{298.15}$ kcal/mol
T. C. Ehlert	$2\text{MgF}(\text{g}) = \text{Mg}(\text{g}) + \text{MgF}_2(\text{g})$	-34.76 $\pm$ 0.74	-70 $\pm$ 19	-52.8 $\pm$ 1.3*
	$2\text{MgF}(\text{g}) = \text{Mg}(\text{g}) + \text{MgF}_2(\text{c})$	-126.66 $\pm$ 0.80	-92 $\pm$ 21	-53.4 $\pm$ 1.2*
G. Herzberg	$\text{AlF}_3(\text{g}) + 2\text{Mg}(\text{g}) = \text{AlF}(\text{g}) + 2\text{MgF}(\text{g})$	18.66 $\pm$ 0.40	2.7 $\pm$ 3.2	-67.7 $\pm$ 1.0*
A. O. Gaydon	$\text{MgF}(\text{g}) \rightarrow \text{Mg}(\text{g}) + \text{F}(\text{g})$	$D_0^o = 4.2$ eV	$D_0^o = 3.2 \pm 0.7$ eV	-42.6 $\pm$ 16.1

*Based on $\Delta H_f^{298.15}$ value by the third law method.

Heat Capacity and Entropy

All the molecular constants are taken from G. Herzberg, loc. cit., except a_e which is estimated.

Dec. 31, 1960; June 30, 1965

NITROGEN MONOFLUORIDE (NF)

(IDEAL GAS)

MOL. WT. = 33.0051

Ground State Configuration $(\frac{1}{2})$

$S^\circ_{298.15} = 51.427 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$\Delta H^\circ_f = 59.5 \pm 8 \text{ kcal. mole}$

$\Delta F^\circ_f = 59.5 \pm 8 \text{ kcal. mole}$

Electronic Levels and Quantum Weight

$\frac{E_1, \text{ cm.}^{-1}}{0} = \frac{g_1}{5}$

$\mu_0 \times 10^{-18} = [12.175]$

$\sigma = 1$

$r_e = [1.51 \text{ \AA}]$

$\nu_0 = 1115 \text{ cm.}^{-1}$

$B_e = [-.923] \text{ cm.}^{-1}$

Heat of Formation.

The heat of formation was obtained by taking an average of two estimates of the dissociation energy of NF.

The first estimate of 5.15 e.v. (72.4 kcal./mole) was obtained from V. C. Price, T. R. Pasmore and D. M. Rossner Discussion Faraday Soc. 55, 201 - 11 (1963). The second estimate of 70.4 kcal./mole was obtained by taking one-half the dissociation energy of NF₂ (g) calculated from JANAF values. The ΔH°_f 298.15 for NF (g) was then calculated with auxiliary JANAF data from a dissociation energy of 71.4 kcal./mole.

Heat Capacity and Entropy.

The ΔH°_f value was obtained from infrared studies of D. E. Milligan and M. E. Jacox, J. Chem. Phys. 40, 2461 (1964). The r_e value was estimated from Duggeheimer's relation for single bonded molecules. [K. M. Duggeheimer, Proc. Phys. Soc. (London), 59, 456 (1946)] The enthalpicity constant x_0 was estimated by assuming the separation of the vibrational levels to be a linear function of the vibrational quantum number. The λ_e value was then calculated using the Morse potential function; B_e was determined from the bond length. The ground state configuration was assumed to be the same as that in NFR. The principal moment of inertia is $3.05247 \times 10^{-39} \text{ g. cm.}^2$

Bond lengths and angles: N-O distance = 1.13 Å N-F distance = 1.52 Å O-N-F angle = 110.2°

Moments of inertia: I_A = 8.8135 X 10⁻⁴⁰ g. cm.² I_B = 70.8354 X 10⁻⁴⁰ g. cm.² I_C = 79.8375 X 10⁻⁴⁰ g. cm.²

O-N-F angle = 110.2°

σ = 1

Heat of Formation

For the reaction 2NO(g) + F₂(g) → 2ONF(g), H. S. Johnston and H. J. Bertin, J. Am. Chem. Soc. 81, 5402 (1959), report ΔH_f^o 298.15 = -74.8 ± 0.8 kcal., determined calorimetrically. This yields -15.7 ± 0.4 kcal. mole⁻¹ for ΔH_f^o 298.15.

Heat Capacity and Entropy

C. V. Stephenson and E. A. Jones, J. Chem. Phys. 20, 135 (1952), report the frequencies, obtained from the infrared spectrum, and moments of inertia, obtained from the microwave spectrum.

Product of the Moments of Inertia: $I_A I_B I_C = 6.401698 \times 10^{-115} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The heat of reaction at 25°C for direct synthesis of nitryl fluoride from nitrogen dioxide with fluorine ($\text{NO}_2(\text{g}) + 1/2 \text{F}_2(\text{g}) = \text{NO}_2\text{F}(\text{g})$) has been measured calorimetrically as $-33.9 \text{ kcal. mole}^{-1}$ by J. D. Breszale and R. O. MacLaren, "Thermochemistry of Oxygen-Fluorine Bonding" (Final Tech. Summary Report, Contract No. Nonr 3433(00), ARPA Order No. 184-62) United Technology Corporation, Sunnyvale, Calif., Mar. 1963. The heat of formation, $\Delta H_f^\circ 298 = -26.0 \text{ kcal. mole}^{-1}$, for $\text{NO}_2\text{F}(\text{g})$ was then derived. The values of $\Delta H_f^\circ 298 = -20 \pm 5$ and $-19 \pm 2 \text{ kcal. mole}^{-1}$ were issued in their second and third quarterly tech. reports, and have been quoted in the literature by E. Tschukow-Roux, J. Phys. Chem. 66, 1636 (1962).

G. Hetherington and P. L. Robinson, Special Publication No. 10, The Chem. Soc., London, 1957 quoted $\Delta H_f^\circ = 26 \text{ kcal. mole}^{-1}$ (presumably it has a minus sign) for $\text{NO}_2\text{F}(\text{g})$ which was derived from the heat of solution measured by Nichols and Robinson, a private communication to Hetherington and Robinson.

Heat Capacity and Entropy.

D. F. Smith and D. W. Magnuson, Phys. Rev. 87, 226 (1952), have measured the moments of inertia from microwave spectrum of $\text{NO}_2\text{F}(\text{g})$. In order to calculate the bond distances, given as N-F = 1.35 Å and N-O = 1.23 Å, the bond angle O-N-O was assumed to be 125°. The selected bond distances and angle were obtained from L. Clayton, Q. Williams and T. Weatherly, J. Chem. Phys. 30, 1328 (1959). Clayton et al. assumed the bond angle O-N-O in $\text{NO}_2\text{F}(\text{g})$ should be the same as that in $\text{NO}_2\text{Cl}(\text{g})$, and then calculated the bond distances N-F and N-O from Smith and Magnuson's data of the moments of inertia.

The selected vibrational frequencies were obtained from the infrared and Raman spectra measurements by R. Dodd, J. Rolfe and L. Woodward, Trans. Faraday Soc. 52, 145 (1956).

The three principal moments of inertia are $I_A = 6.3659 \times 10^{-39}$, $I_B = 7.3383 \times 10^{-39}$ and $I_C = 13.7041 \times 10^{-39} \text{ g. cm.}^2$

[450] (1)	

Bond Distance: O-N = 1.29 ± 0.05 Å N-O' = 1.39 ± 0.05 Å O'-F = 1.42 ± 0.05 Å

Bond Angle: O-N-O = 125° ± 5° F-O'-N = 105° ± 5° O'-F = 1

Angle between NO₂F plane and O₂NO' plane = 90°.

Product of the Moments of Inertia: I_AI_BI_C = 3.88637 X 10⁻¹¹⁴ g.³ cm.⁶

Heat of Formation.

The value, 2.5 ± 0.5 kcal. mole⁻¹, for the heat of formation of FNO₃(g) was obtained from R. Anderson, et al., "Thermochemistry of Oxygen-Fluorine Bonding," UTC 2002-Q74, United Technology Corporation, Sunnyvale, California, March 1, 1961, through February 28, 1962. The value of ΔH_f^o reported by O. G. Telakin, et al., Russ. J. Phys. Chem., 36, 561 (1962) was -4.2 ± 0.9 kcal. mole⁻¹ at 294°K.

Heat Capacity and Entropy.

Vibrational frequencies were estimated by comparison with those of HNO₃(g) reported by A. Palm and M. Kilpatrick, J. Chem. Phys. 23, 1562 (1955). Bond distances and angles were taken from L. Pauling and L. O. Brockway, J. Am. Chem. Soc. 59, 13 (1937). The three principal moments of inertia are: 8.8598 X 10⁻³⁸, 1.8572 X 10⁻³⁸, and 2.3618 X 10⁻³⁸ g. cm.². The possible existence of restricted internal rotation in the molecule was not considered. Thus the values of C_p and S^o calculated may be low.

FNO₃

$$T_m = 1269 \pm 2^\circ\text{K}$$

Heat of Formation

The heats of solution and reaction of NaF(c) have been determined by many investigators. Incorporating their reported data with auxiliary ΔH_{298}° values (1, 2), we calculate the corresponding values of ΔH_{298}° (NaF, c). The results are presented in the table below. The adopted ΔH_{298}° (NaF, c) is $-137.52 \pm 0.2 \text{ kcal/mol}$.

Investigator	Reaction*	Temperature, °K	Concentration NaF·H ₂ O	No. of determinations	ΔH_{298}° kcal/mol	ΔH_{298}° kcal/mol
1. Guntz (1884)	A	285	400	1	0.13	-137.42
2. Latimer - Jolly (1953)	A	298	1850	2	0.23 ± 0.01	-137.52
3. Hepler et al. (1953)	A	298	1540	1	0.22 ± 0.01	-137.51
4. Davies - Benson (1985)	A	298	222	1	0.24 ± 0.01	-137.53

9. Vorob'yev - Skuratov (1960)	E	298	—	5	-325.5 ± 2.2	-137.13

*A represents NaF(c) = NaF(in H₂O) and $\Delta H_{298}^\circ = \Delta H_{298}^\circ$; B, NaOH(200 H₂O) + HF(200 H₂O) = NaF(401 H₂O) + H₂O(lat·mol H₂O); C, NaCl(c) + 1/2 F₂(g) = NaF(c) + 1/2 Cl₂(g); D, NaCl(c) + HF(5.716 H₂O) = NaF(c) + HCl(12.731 H₂O); E, 4Na(c) + CF₄(g) = 4NaF(c) + C (graphite).

Heat Capacity and Entropy

The low temperature heat capacities, 0.05 - 15°K and 54.01 - 295.86°K, were measured by Harrison et al. (10) and King (11), respectively. These two sets of data are joined smoothly with the high temperature heat capacities at 298°K which were derived from the enthalpy measurements, 406.1 - 1282.2°K, determined by O'Brien and Kelley (12). The Cp values above 1282.2°K are obtained by linear extrapolation. S₂₉₈ is calculated using the adopted low temperature heat capacities and S₂₉₈ = 0.555 eu.

Frank (13) commented that the temperature measurements of O'Brien and Kelley (12) seemed to be about 20°K high at 1000°K with a smaller error at lower temperatures. A correction for the assumed error in the temperature measurement was used in the previous JANAF table. However, Douglas and Dittmars (14) have questioned this correction, since new enthalpy data for AlF₃ yielded Cp values in better agreement with the original Cp values of O'Brien and Kelley than with the corrected values of Frank. The α + β transition of AlF₃(c) was found in the range 723 - 8°K, while O'Brien and Kelley selected 727°K based on a point at 728.1°K in the β region and a point at 724.9°K in the pretransition region. Frank's correction yields an error of 8° at 727°K, yet the true error appears to be negligible (<2°) for AlF₃(c). Based on the above reasoning and the comparison of the Cp curve of NaF(c) with those of NaCl(c), LiCl(c), and LiF(c) in the temperature range 300 - 1300°K, we adopt the high temperature enthalpy data of O'Brien and Kelley without any correction.

The low temperature heat capacities in the temperature ranges 81 - 190 and 198 - 273°K were also measured by Koref (15); and high temperature enthalpies at temperatures 268 - 1071 and 290 - 1287°K were reported by Krestovnikov and Karetnikov (16), and Lyashenko (17), respectively. They are not used for evaluation.

Melting Data

See the NaF(l) table for details.

Heat of Sublimation

ΔH_{298}° is the difference between ΔH_{298}° for NaF(g) and NaF(c).

Sodium Fluoride (NaF)

(Liquid)

GFW = 41.9882

SODIUM FLUORIDE (NaF)

(LIQUID)

GFW = 41.9882

$$S_{298.15}^{\circ} = 17.559 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = -130.545 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 7.97 \text{ kcal/mol}$$

$$\Delta H_m^{\circ}(\text{to mixture}) = 42.1 \text{ kcal/mol of NaF(l)}$$

$$T_m = 1269 \pm 2^{\circ}\text{K}$$

$$T_b = 2060^{\circ}\text{K}$$

Heat of Formation

$\Delta H_{298}^{\circ}(\text{l})$ is obtained from $\Delta H_{298}^{\circ}(\text{c})$ by adding ΔH_m° and the difference between H_{1269}° and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

The heat capacities of NaF(l) are derived from the enthalpy data, 1267.6 - 1746.5°K, determined by O'Brien and Kelley (1). A glass transition temperature is assumed at 900°K, i.e. the heat capacities below 900°K are taken from those for NaF(c). The Cp values above 1746.5°K are obtained by extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

The value of T_m has been reported as (°K): 1313 (2), 1285 (3), 1270 (3, 4, 5), 1269 (6), 1268 (7, 8, 9), 1267 (10, 11, 12), 1265 (13), 1263 (14), and 1253 (15). We select $T_m = 1269^{\circ}\text{K}$. The value 1285°K reported by O'Brien and Kelley seems unreasonably high and is not adopted. The cause of this discrepancy is still unresolved (17). The heat of melting is calculated as the difference between the adopted enthalpies for NaF(c) and NaF(l) at 1269°K. Kelley (18) derived ΔH_m° to be 5.87 - 8.43 kcal/mol, based on 13 sets of molten salts equilibrium data involving NaF. The value $\Delta H_m^{\circ} = 8.03$ kcal/mol reported by O'Brien and Kelley is not used.

Vaporization Data

T_b is the temperature at which the partial pressures of NaF(g) and $\text{Na}_2\text{F}_2(\text{g})$ in equilibrium with NaF(l) equal one atmosphere. The vapor composition at T_b is evaluated as NaF 84.81 and Na_2F_2 15.19. The heat required to vaporize one mole of liquid to form 0.868 mole of vapor mixture of the above composition at T_b is calculated to be 47.1 kcal/mol. Ruff et al. (16) measured the vapor pressure of NaF(l) in the temperature range of 1899 - 1974°K and reported $T_b = 1978^{\circ}\text{K}$.

Ground State Configuration 1₂

$$\Delta H_F^\circ = -69.03 \pm 0.5 \text{ kcal/mol}$$

$$\Delta H_F^\circ = -69.42 \pm 0.5 \text{ kcal/mol}$$

Electronic Levels and Quantum Weights

$$\frac{g_i}{\sum_i g_i} = \frac{1}{2}$$

$$\omega_e = 536.10 \pm 0.35 \text{ cm}^{-1}$$

$$\rho_e = 0.4369 \text{ cm}^{-1}$$

$$\sigma_e = 0.00456 \text{ cm}^{-1}$$

$$\sigma = 1$$

$$\rho_e = 1.9260 \text{ \AA}$$

Heat of Formation

The total pressures of NaF(g) and Na₂F₂(g), in equilibrium with NaF(c, *l*) at temperatures 1020 - 1974°K, have been determined by many investigators, using manometric (1, 2, 5), torsion-effusion (6, 8), Knudsen-effusion (3, 7), transpiration (9), and molecular-beam velocity-selector (9, 10) methods. In order to evaluate ΔH_F° (NaF, g) we have used a trial and error variation of ΔH_F° and ΔH_F° for the monomer and dimer such that the ΔH_F° values derived by the second and third law methods are in reasonable agreement.

Incorporating ΔH_F° = 68.12 and ΔH_F° = 61.12 and 58.75 kcal/mol for NaF and Na₂F₂, respectively, with JANAF functions for NaF(c), NaF(l), NaF(g) and Na₂F₂(g), we derive the partial pressures of NaF monomer from the reported total pressures. Based on the calculated partial pressures of NaF(g), the corresponding heats of vaporization are evaluated by the second and third law methods. Using the third law ΔH_F° and ΔH_F° = -137.52 and -130.545 kcal/mol for NaF(c) and NaF(l), we obtain values of ΔH_F° for NaF(g). The results are presented in the table below. The ΔH_F° (NaF, g) value adopted is -69.42 kcal/mol.

The vapor pressure data reported by Miller and Kusch (3) and Eisenstadt et al. (10) are not consistent with the other sets and are not used for evaluation.

Gaydon (11) and Herzberg (12) reported D_0° = 114.2 ± 6.9 (4.95 ± 0.3 eV) and 122.2 kcal/mol (5.3 eV), respectively. Using JANAF ΔH_F° values for Na(g) and F(g), we obtain ΔH_F° (NaF, g) = -70.5 ± 5.8 and -78.5 kcal/mol. Employing flame-photometric method, Bulewicz et al. (13) and Page and Sugden (14) derived D_0° = 121 ± 7 and 119 ± 120 kcal/mol for NaF(g), which lead to ΔH_F° (NaF, g) = -77.3 ± 7 and -75 to -76 kcal/mol.

Heat Capacity and Entropy

Veazey and Gordy (15) have measured the rotational transitions of NaF in the millimeter- and sub-millimeter-wave region with a high-resolution molecular-beam absorption spectrometer. The derived values of ω_e , $\omega_e x_e$, B_e , $B_e x_e$ and r_e are adopted here.

Using the molecular beam electric resonance method, Bauer and Lew (16) measured the transition between the $J = 0$ and $J = 1$ rotational levels of Na₂F₂ in the three lowest vibrational states. Radio-frequency transitions for Na₂F₂ have been observed by Hollowell et al. (19). Infrared spectra of NaF have been analyzed by Sneison and Pitzer (17), Ritchie and Lew (18), and Baikov and Vasilevskii (20). The molecular constants derived by the above authors are similar to the values adopted, except the value $\omega_e = 550 \text{ cm}^{-1}$ (17) which is different from the value 536.1 cm⁻¹ reported by Veazey and Gordy (15).

FLUORINE MONOXIDE (F0)

(IDEAL GAS)

GF_W = 34.998

Ground State Configuration [2Π]
S_{298.15} = 51.77 ± 0.3 gibbs/mol
ΔH_F^o = [26 ± 10] kcal/mol
ΔH_F^o_{298.15} = [26 ± 10] kcal/mol

Electronic Levels and Quantum Weights

ϵ_i , cm ⁻¹	g_i
0	[4]
[29000]	[4]
$w_e x_e = [15]$ cm ⁻¹	$\sigma = 1$
$\alpha_e = [0.020]$ cm ⁻¹	$r_e = [1.30]$ Å
$w_e = 1056$ cm ⁻¹	
$B_e = [1.148]$ cm ⁻¹	

Heat of Formation

Several values have been proposed for the heat of formation of F0(g). V. H. Dibeler, R. M. Reese and J. L. Franklin, J. Chem. Phys. 27, 1296 (1957), obtained D₀(F0,g) = 24 kcal from electron impact studies. However, theoretical estimates give D₀ values in the range 45 - 56 kcal. W. C. Price, T. R. Pasmore and D. M. Roessler, Discussions Faraday Soc. 35, 207 (1963), estimated 52 kcal for D₀(F0,g).

From a consideration of the central bond energies in FNP and HNH with that in HOOH, using all JANAP values of 101, 109 and 50 kcal, we predict the bond dissociation energy in F0-OF to be 46 ± 4 kcal, which yields D₀(F0,g) = 51 ± 2 kcal. The average F-O bond dissociation energy in F₂O(g) is 49.8 ± 0.5 kcal. Also, since there is one less antibonding electron in F0 than in F₂, we should expect the F-O bond to be greater than that in F₂(38 kcal). Thus a median value of D₀(F0,g) = 51.4 ± 10 kcal is adopted here which leads to ΔH_F^o(F0) = 26 kcal/mol.

Heat Capacity and Entropy

The fundamental frequency is obtained by adding 2w_ex_e to the value reported by A. Arkell, R. R. Reinhard and L. P. Larson, J. Am. Chem. Soc. 87, 1016 (1965), from matrix isolation studies. The bond length was taken equal to that in the isoelectronic molecule O₂(g). The value of w_ex_e was obtained from the Morse potential function and the assumed dissociation energy. The rotational constant α_e was also estimated from the above parameters and the Morse potential curve. The 2Π ground state is that predicted by molecular orbital theory and the first excited state would also be 2Π. By analogy with the isoelectronic O₂⁻(g) states, the first excited level was estimated at 29000 cm⁻¹.

MOL. WT. = 82.9

TITANIUM OXIDE FLUORIDE (TiOF)

(IDEAL GAS)

$$\Delta H_f^0 = [-103.0] \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 = [-103.5] \text{ kcal. mole}^{-1}$$

Point Group [C_{2v}]

$$S_{298.15}^0 = [89.837] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

$$\frac{\omega}{\text{cm.}^{-1}}$$

$$[800] (1)$$

$$[300] (2)$$

$$[740] (1)$$

$$\text{Bond Distances: Ti-O} = [1.62] \text{ \AA} \quad \text{Ti-F} = [1.74] \text{ \AA}$$

$$\text{Bond Angle: O-Ti-F} = [180^\circ] \quad \sigma = 1$$

$$\text{Rotational Constant: } B_0 = [0.1705] \text{ cm.}^{-1}$$

Heat of Formation

ΔH_f^0 was estimated as -103 kcal. mole⁻¹ by J. S. Oordon, AstroSystems, Inc., Caldwell Typ., N. J., private communication, January 10, 1963. ΔH_f^0 298.15 was then calculated.

Heat Capacity and Entropy

Molecular constants were estimated by J. S. Oordon, loc. cit. Principal moment was 16.419×10^{-39} g. cm.²

Sept. 30, 1966

MONOFLUORINE DIOXIDE (F₀₂) (IDEAL GAS) OPW = 50.9972

Point Group C_{2v}
S_{298.15} = 61.9 gibbs/mol
Ground State Quantum Weight = 2
ΔH_f⁰ = 3.4 ± 5 kcal/mol
ΔH_f⁰_{298.15} = 3.0 ± 5 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm ⁻¹	
1495.0 (1)	
584.5 (1)	
376.0 (1)	

Bond Distance: O-O = 1.22 Å O-P = 1.58 Å

Bond Angle: O-O-P = 109.5°

Product of the Moments of Inertia: I_AI_BI_C = 7.7504 x 10⁻¹¹⁶ g³cm⁶

G° = 1

Heat of Formation.

The heat of formation for F₂O₂(g) is unavailable in the literature. Based on a kinetic study of the thermal decomposition of F₂O₂(g) reported by R. J. Schumacher and P. Priach, Z. physik. Chem. **B24**, 332 (1934), the enthalpy change for the reaction F₂O₂(g) = F(g) + O₂(g) was estimated to be +17.3 kcal/mol by J. B. Levy and B. K. Kaaley, J. Phys. Chem. **69**, 408 (1965), assuming that the activation energy for the reverse reaction is negligible. From this data the value of ΔH_f⁰_{298.15}(F₂O₂, g) was calculated as +3.2 kcal/mol, using ΔH_f⁰_{298.15} = +4.73 kcal/mol for F₂O₂(g) determined calorimetrically by A. D. Kirshenbaum, A. V. Grosse and J. G. Aston, J. Am. Chem. Soc. **81**, 6396 (1959).

Based on the assumption that the enthalpy change for the reaction F₂O₂(g) = F(g) + O₂(g) is 16.5 kcal/mol, which is half of the enthalpy change for the reaction F₂O₂(g) = 2F(g) + O₂(g), the heat of formation (ΔH_f⁰_{298.15}) for F₂O₂(g) was derived as +2.4 kcal/mol.

The value of ΔH_f⁰_{298.15}(F₂O₂, g) adopted is 3 ± 5 kcal/mol.

Heat Capacity and Entropy.

The vibrational frequencies for F₂O₂(g) were assumed to be the same as those obtained from matrix isolation by P. N. Noble and G. C. Pimentel, J. Chem. Phys. **44**, 3641 (1966). These authors have observed two more frequencies for isotopically substituted F₂O and combined them with those observed by R. D. Spratley, J. J. Turner and G. C. Pimentel, J. Chem. Phys. **44**, 2063 (1966), and performed a normal coordinate analysis. The results confirm the fact that the bond distances and angles in F₂O are essentially the same as those reported for F₂O₂(g) by R. H. Jackson, J. Chem. Soc., 4585 (1962). The same molecular structure for F₂O was also deduced from electron spin resonance and electron paramagnetic resonance data reported by R. W. Fassenden and R. H. Schuler, J. Chem. Phys. **44**, 434 (1966) and P. H. Kasal and A. D. Kirshenbaum, J. Am. Chem. Soc. **87**, 3069 (1965), respectively. Hence this molecular structure was adopted. Two vibrational frequencies, ν₁ and ν₃, for F₂O molecule were also observed by A. Arkell, J. Am. Chem. Soc. **87**, 4057 (1965).

The three principal moments of inertia are: I_A = 1.1103 x 10⁻³⁹, I_B = 7.8182 x 10⁻³⁹ and I_C = 8.9285 x 10⁻³⁹ g cm².

Dec. 31, 1960; Sept. 30, 1962

Phosphorus Monofluoride (PF) (Ideal Gas)

Mol. Wt. = 49.975

 $\Delta H_f^{298.15} = -14 \pm 3 \text{ kcal. mole}^{-1}$ $S_{298.15}^{298.15} = 53.7 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ Ground State Configuration $\sum$

Electronic Level and Multiplicity

$$\frac{\epsilon_1}{\epsilon_2} = \frac{\epsilon_1}{\epsilon_2}$$

 $\omega_e = 846.75 \text{ cm.}^{-1}$ $\omega_e x_e = 4.409 \text{ cm.}^{-1}$ $\alpha_e = 0.00456 \text{ cm.}^{-1}$ $r_e = 1.590 \text{ \AA}$ $\sigma = 1$

Heat of Formation. $\Delta H_f^{298.15}$ was derived from a D_0^0 calculated with spectroscopic constants reported by A. E. Douglas and M. Prackowiak, Can. J. Phys. 40, 832 (1962). The D_0^0 value was calculated using the dissociation and spectroscopic relations given by O. Herzberg in "Spectra of Diatomic Molecules", D. van Nostrand Co., N. Y., 2nd Ed. (1950) pages 93 and 100. If the PF molecule dissociates to the ground state atoms, $P(^3S_{3/2}) + F(^2P_{3/2})$, the corresponding $\Delta H_f^{298.15}$ is $-15 \pm 3 \text{ kcal. mole}^{-1}$. If the dissociation is to the phosphorus ground state and the excited fluorine state, $P(^3S_{3/2}) + F(^2P_{1/2})$, the corresponding $\Delta H_f^{298.15}$ is $-14 \pm 3 \text{ kcal. mole}^{-1}$. The dissociation to an excited $F(^2P_{1/2})$ atom was assumed to obtain the selected $\Delta H_f^{298.15} = -14 \pm 3 \text{ kcal. mole}^{-1}$.

The heat of formation was estimated to be $-17 \text{ kcal. mole}^{-1}$ by J. S. Gordon, "Thermodynamic Data for Combustion Products", January, 1960, Thiokol Chemical Corp. This estimate when changed from white(α) to red(V) phosphorus reference state ($-13 \text{ kcal. mole}^{-1}$) agrees within uncertainty limits with the derived $\Delta H_f^{298.15}$ values.

Heat Capacity and Entropy. The molecular constants were reported by Douglas and Prackowiak (loc. cit.). They photographed and analyzed the electronic spectra of PF in the emission spectrum of a discharge through a mixture of PF_3 and He.

FPb

Lead Monofluoride (PbF)

(Ideal Gas)

Mol. Wt. = 226.21

 ΔH_f° 298.15 = -9.0 $\pm$ 8.2 kcal. mole⁻¹ $S_{298.15}^\circ$ = 59.627 cal. deg.⁻¹ mole⁻¹Ground State Configuration $^2\Pi$

Electronic Levels and Multiplicities

ϵ , cm. ⁻¹	E_1
0	2
8266	2

 $\omega_e = 507.2$ cm.⁻¹ $\omega_e x_e = 2.30$ cm.⁻¹ $B_e = [0.2397]$ cm.⁻¹ $\alpha_e = [0.0017]$ cm.⁻¹ $\sigma = 1$

Heat of Formation. ΔH_f° 298.15 was calculated from the dissociation energy of PbF(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ϵ , ω_e , and $\omega_e x_e$ were given by G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York, 1950. B_e and α_e were estimated by J. S. Gordon, Astrosystems, Inc., private communication, May, 1962.

Silicon Monofluoride (SiF)

(Ideal Gas) $GF^\circ = 47.0844$

SILICON MONOFLUORIDE (SiF)

(IDEAL GAS)

 $GF^\circ = 47.0844$ Ground State Configuration $2\pi_r$ $\Delta H_f^\circ = -5.0 \pm 3 \text{ kcal/mol}$ $S_{298.15}^\circ = 53.937 \pm 0.01 \text{ gibbs/mol}$ $\Delta H_f^\circ = -4.6 \pm 3 \text{ kcal/mol}$

 $\omega_e X_e = 4.74 \pm 0.03 \text{ cm}^{-1}$ $\sigma = 1$ $B_e = 0.58138 \text{ cm}^{-1}$ $r_e = 1.6008 \text{ \AA}$

Heat of Formation

Ehlert and Margrave (1) have studied mass-spectrometrically the reaction $\text{Si(g)} + \text{SiF}_2(\text{g}) \rightarrow 2\text{SiF(g)}$ by monitoring the intensities of the Si^+ , SiF^+ , and SiF_2^+ ions in an equilibrium system containing CaF_2 and Si. The ionization cross-sections are assumed to cancel so that equilibrium constants can be obtained directly from the ion intensities. We have analysed the above data using present JANAF functions and obtain $\Delta H_f^\circ = 23.5 \pm 3 \text{ kcal}$ by the third law technique with a drift of $-0.8 \pm 1.1 \text{ eu}$, the second law value is $23.9 \pm 7 \text{ kcal}$. We adopt the third law value which with JANAF auxiliary data gives $\Delta H_f^\circ(\text{SiF}, g) = -4.6 \pm 3 \text{ kcal/mol}$.

Johns and Barrow (2) have selected $D_0^\circ(\text{SiF}, g) = 125 \pm 10 \text{ kcal/mol}$, from Birge-Sponer extrapolations of several states, this gives $\Delta H_f^\circ = 0.1 \pm 10 \text{ kcal/mol}$ in good agreement with the adopted value.

Heat Capacity and Entropy

The molecular constants of the various electronic levels have been documented by Johns and Barrow (2), Verma (3), Barrow et al. (4), and Appelblad et al. (5). The approximation involving the use of the ground state constants for all electronic levels is used since it introduces negligible error in this molecule.

TITANIUM MONOFLUORIDE (TiF)

(IDEAL GAS)

GFW = 66.8984

Ground State Configuration (° 2)

 $S^{\circ}_{298.15} = 56.7 \pm 2.0$ gibbs/mol $\Delta H^{\circ}_0 = [-16 \pm 10]$ kcal/mol $\Delta H^{\circ}_{298.15} = [-16 \pm 10]$ kcal/mol

Electronic Levels and Quantum Weights

ϵ_i , cm ⁻¹	g_i	ϵ_i , cm ⁻¹	g_i
0	[4]	[6000]	[4]
[1000]	[4]	[8000]	[4]
[2000]	[4]	[10000]	[4]
[4000]	[4]		

 $\omega_e X_e = [590]$ cm⁻¹ $\omega_e = [6.6]$ cm⁻¹ $\sigma = 1$ $B_e = [0.328]$ cm⁻¹ $r_e = [1.95]$ Å

Heat of Formation

The heat of formation, ΔH°_{298} , of TiF(g) is calculated from the dissociation energy, D°_0 . The dissociation energy is estimated as 148 ± 6 kcal/mol using the corresponding quantity for TiF₂(g) and the relation $D(\text{HF})/D(\text{HF}_2) = 0.46 \pm 0.02$ which Zmbov and Margrave (1) found held for other mono- and di-fluorides.

Heat Capacity and Entropy

The vibrational frequency, ω_e , and anharmonic vibrational term, $\omega_e X_e$, are estimated from those of the alkali and mercury monohalides. The interatomic distance, r_e , is estimated from those of TiCl(g), TiF₂(g) and TiF₃(g). B_e is calculated from r_e . The ground state term and electronic levels are estimated from the ground state multiplet of Ti (2).

Heat of Formation

The heat of formation, ΔH_f^o₂₉₈(WF₂g) = 92.3 kcal/mol, is calculated from the bond dissociation energy D₂₉₈^o(WF) = 130 ± 15 kcal/mol. This value of D₂₉₈^o is estimated to be slightly higher than the average bond dissociation energy of WF₂(g) by analogy with the WCl₂ system.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in WF₂(g). This distance is then used with Ouggenheimer's relation to calculate the fundamental vibrational frequency, w_e (K. M. Ouggenheimer, Proc. Phys. Soc. 58, 456 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = w_e/4(D_0 + 0.5 w_e) = 0.0042$. The rotational constant B_e is calculated from the estimated bond distance. The value of w_e is calculated from the Morse potential function. The moment of inertia is 9.575×10^{-39} g cm².

The ground state configuration, low lying electronic levels and their quantum weights are estimated based on the tentative molecular orbital diagram for TaO given by N. Weitzner, Jr., and D. McLeod, Jr., J. Chem. Phys. 42, 882 (1965). Using this scheme, we obtain the ground state configuration as $n^2 d^4$, which yields a $^2\Delta$ ground state. The first excited state is assumed to have $n^2 d^4$ which yields a $^2\Phi$ state. Higher levels are considered to be formed by transition to n^2 antibonding orbitals, and by analogy with TaO these are assumed to lie in the 15000 cm⁻¹ region. The degeneracy of these levels is estimated roughly from the large number of possible configurations.

Zirconium Monofluoride (ZrF)

 $\omega_e X_e = [628.0] \text{ cm}^{-1}$ $\sigma = 1$ $r_e = [1.90] \text{ \AA}$ $B_e = [0.29699] \text{ cm}^{-1}$

Heat of Formation

Based on [D(ZrF)/D(ZrF₂)] = 0.46, as indicated by recent work on the fluorides of Groups II and IV elements (1, 2, 3, 4, 5), and D₀(ZrF₂) = 318.1 kcal/mol, the D₀(ZrF) is calculated as 146.3 kcal/mol. Using ΔH_{f,0}⁰(Zr, g) = 147.99, ΔH_{f,0}⁰(F, g) = 18.36, and D₀(ZrF₂, g) = 146.3 kcal/mol, we derive ΔH_{f,0}⁰(ZrF, g) = 20.0 or ΔH_{f,298}⁰(ZrF, g) = 19.8 ± 5 kcal/mol which is adopted. The ΔH_{f,298}⁰ for ZrF(g) was evaluated as approximately 16 ± 5 kcal/mol by Murad and Hildenbrand (8), employing different D(ZrF₂) value. Their value is in agreement with the adopted one, within the assigned uncertainty.

Heat Capacity and Entropy

The ground state configuration is taken from the ground state multiplet of Zr⁴⁺ (g). The electronic levels are estimated as three times higher than those of TiF(g) and the quantum weights are assumed to be the same. ω_e is taken to be approximately the same as the Zr-F stretching frequency ν_1 for ZrF₄(g). B_e is calculated from the formula $B_e = (2.798076 \times 10^{-39})(I_e)^{-1}$ where $I_e = \mu r_e^2$, μ = reduced mass of ZrF(g), $r_e = 1.90 \text{ \AA}$ which is estimated from those of ZrF₄, CF₄, ClF and other related gaseous molecules. a_e is derived from B_e , ω_e , and $\omega_e X_e$ (estimated), according to the method suggested by Herzberg (2). The moment of inertia is $9.473 \times 10^{-39} \text{ c cm}^2$.

$$\Delta H_f^0 = -168.6 \pm 10 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 298.15 = -168.7 \pm 10 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = [12.4] \text{ kcal. mole}^{-1}$$

$$\Delta H_g^0 298.15 = 75.6 \pm 2.0 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 20.79 \pm 0.04 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = [1373]^\circ \text{K.}$$

Heat of Formation.

The equilibrium pressures for the reaction $\text{FeF}_2(\text{c}) + \text{H}_2(\text{g}) = \text{Fe}(\text{c}) + 2\text{HF}(\text{g})$ have been measured by K. Jelinek and A. Rudat, Z. anorg. allgem. Chem. **175**, 281 (1928) at 775, 875 and 975°K. The enthalpy change ($\Delta H_f^0 298.15$) of the reaction was evaluated by the second and third law methods to be 27.19 and 39.08 kcal. mole⁻¹, respectively. Based on the third law value of $\Delta H_f^0 298.15$, the $\Delta H_f^0 298.15$ (FeF₂, c) was calculated to be -168.7 ± 10 kcal. mole⁻¹. The drift in the third law values of $\Delta H_f^0 298.15$ was evaluated to be 13.3 ± 1.8 e.u.

Heat Capacity and Entropy.

T_m was estimated as 1100°C based on the data reported by W. Biltz and E. Rehlf, Z. anorg. allgem. Chem. **165**, 363 (1927). The value of ΔH_f^0 was calculated using $\Delta S_m^0 = 9$ e.u. which was assumed to be the same as the corresponding value for MgF₂(c). The value of $\Delta H_f^0 298.15$ was obtained from E. Catalano and J. M. Stout, loc. cit., in which a sharp maximum C_p of 17.8 cal. deg.⁻¹ mole⁻¹ at 78.35°K. was reported. The $S_{298.15}^0$ value was based on $S_{15}^0 = 0.039$ e.u.

Melting Data.

T_m was estimated as 1100°C based on the data reported by W. Biltz and E. Rehlf, Z. anorg. allgem. Chem. **165**, 363 (1927). The value of ΔH_f^0 was calculated using $\Delta S_m^0 = 9$ e.u. which was assumed to be the same as the corresponding value for MgF₂(c).

Heat of Sublimation.

The value of $\Delta H_g^0 298.15$ was obtained from J. L. Margrave, "Research in Fluorine Chemistry", Progress Report No. 7, 1 January to 31 March 1965, William Marsh Rice University, Houston, Texas. See FeF₂(g) table for details.

IRON DIFLUORIDE (FeF₂)

(LIQUID)

MOL. WT. = 93.8438

F₂FeS°_{298.15} = [21.951] cal. deg.⁻¹ mole⁻¹ΔH_f^o_{298.15} = [-161.229] kcal. mole⁻¹ΔH_m^o = [12.4] kcal. mole⁻¹T_m = [1373]°K.ΔH_v^o = [53.64] kcal. mole⁻¹T_b = [2110]°K.

Heat of Formation.

The value of ΔH_f^o_{298.15} (FeF₂, l) was obtained from ΔH_f^o_{298.15} (FeF₂, c) by adding ΔH_m^o and the difference between H_m^o - H_l^o_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity for FeF₂(l) was estimated by comparison with those for FeCl₂(c), MgCl₂(c), MgF₂(c), CaCl₂(c) and CaF₂(c). The C_p(FeF₂, l) value was assumed to be constant in the temperature range, 298.15 - 3000°K. The entropy (S°_{298.15}) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See the FeF₂(c) table for details.

Vaporization Data.

T_b is calculated as the temperature at which the free energy change of the reaction FeF₂(l) = FeF₂(g) approaches zero. The difference between ΔH_f^o for FeF₂(l) and FeF₂(g) at T_b is ΔH_v^o.

σ = 2

Heat of Formation.

The rate of sublimation of FeF₂(c) was measured between 965 and 1149°K. by the Knudsen technique employing the high temperature magnetic mass spectrometer by John L. Margrave, "Research in Fluorine Chemistry", Progress Report No. 7, 1 January to 31 March 1965, William March Rice University, Houston, Texas. The only vapor species of importance is FeF₂(g). From the vapor pressure data the third law heat of sublimation (ΔH_f^o 298.15) was reported as 75.6 ± 2.0 kcal. mole⁻¹. The sum of the values of ΔH_f^o 298.15 and ΔH_f^o 298.15 for FeF₂(c) is the ΔH_f^o 298.15 (FeF₂, g).

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The Fe-F bond distance was estimated from that in FeF₂(c) reported by W. H. Baur, Acta Cryst. 11, 488 (1958). The vibrational frequencies, ω_i and ω_i, were estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The values of ω_i, electronic levels and quantum weights were estimated by comparison with those for FeCl₂(g). See FeCl₂(g) table for details. The moment of inertia is 2.04404 X 10⁻³⁹ g. cm.²

(CRYSTAL)

POTASSIUM BIFLUORIDE (KHF₂)

$$\Delta H_f^o = -220.74 \pm 0.35 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{298.15} = -221.90 \pm 0.35 \text{ kcal. mole}^{-1}$$

$$\Delta H_c = 2.671 \pm 0.01 \text{ kcal. mole}^{-1}$$

$$\Delta H_m = 1.582 \pm 0.003 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^o = 25.0 \pm 0.1 \text{ cal. deg. mole}^{-1}$$

$$T_c = 469.8^\circ\text{K.}$$

$$T_m = 511.8^\circ\text{K.}$$

Heat of Formation.

The heat of formation was obtained from the enthalpy of decomposition measurements of M. L. Davis and E. F. Westrum, J. Phys. Chem. 65, 339 (1961) who gave $\Delta H_{500}^o = 18.82 \pm 0.05 \text{ kcal. mole}^{-1}$ and the heats of formation of HF(g) and KF(c) in conjunction with enthalpies at 500°K. from E. F. Westrum and K. S. Pitzer, J. Am. Chem. Soc. 71, 1940 (1949). A third law analysis of the decomposition vapor pressure by Westrum and Pitzer, loc. cit. did not agree with enthalpy of decomposition measurements, giving $\Delta H_{298}^o = 21.274 \pm 0.2 \text{ kcal. mole}^{-1}$ as compared to Davis and Westrum's value at 298°K. of $21.505 \pm 0.05 \text{ kcal. mole}^{-1}$. As the liquid vapor pressure data, which were not used, have a large trend in the third law heat of vaporization with temperature it was suspected that the pressure measurements were in error. This is borne out somewhat by a small trend in the values over the solid in the range 480-500°K.

Heat Capacity and Entropy.

Westrum and Pitzer, loc. cit., have measured the heat capacity from 16°K. to the melting point. Their data has been used to calculate the entropy at 298° using a T^3 law extrapolation below 16°K., giving $S_{16}^o = 0.103 \text{ e.u.}$

Melting and Transition Data.

The temperatures of melting and transition and the heats of melting and transition were taken from Davis and Westrum, loc. cit.

Heat of Formation.

This was calculated from the heat of formation of the crystal, the heat of melting and H°_{511.8}-H°_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The entropy was determined from that of the crystal in a manner analogous to the heat of formation. The heat capacity just above the melting point was measured by E. F. Westrum and K. S. Pitzer, J. Am. Chem. Soc. 71, 1940 (1949) and was assumed constant above the melting point. A glass type transition was assumed at 341°K. below which the heat capacity is that of the solid.

Melting.

See table for crystal.

Decomposition.

The temperature of decomposition was estimated from the free energy cross-over and is the point where the HF(g) reaches 1 atm. It should be noted that the vapor pressures over the liquid of Westrum and Pitzer, loc. cit. are apparently in error, being high by roughly 12%. A 3rd law analysis at each vapor pressure point gave an almost constant heat of reaction in the solid region but in the liquid region the value changed abruptly with temperature. The only factors which were variable were the pressure and the liquid heat capacity, a trial change of 20% in the heat capacity produced an almost negligible change in the heat of reaction. Thus the vapor pressures over the liquid appear to be in error and the decomposition point of 702°K. obtained by extrapolating to 1 atmosphere is also in error.

MERCURY DIFLUORIDE (HgF₂) (Crystal)

Mol. Wt. = 238.61

 ΔH_f^0 238.15 = [-101.0 ± 10.0] kcal. mole⁻¹ $S_{298.15}^0$ = [27.800 ± 2.0] cal. deg.⁻¹ mole⁻¹ T_m = 918°K ΔH_m = [5.5 ± 1.0] kcal. mole⁻¹

Heat of Formation. Estimated by comparison of the mercurous and mercuric halides.

Heat Capacity and Entropy. The heat capacity was assumed to be a linear function of temperature and was estimated to be 7.0 cal. deg.⁻¹ per atom at the melting point. The entropy was estimated by comparison with the other mercuric and mercurous halides and use of additive entropy constants for the halogens from K. K. Kelley (Private Communication, 1950).

Melting. T_m was given by O. Ruff and G. Bahlau, Ber. 51, 1752 (1918). The heat of melting was from L. Brewer, paper 7, National Nuclear Energy Series A-193 "Thermodynamics" McGraw-Hill (1950).

MERCURY DIFLUORIDE (HgF₂)
(Liquid)

Mol. Wt. = 238.61
ΔH_f^o 298.15 = [-96.772 ± 10.0] kcal. mole⁻¹
S_{298.15}^o = [32.083 ± 2.0] cal. deg⁻¹ mole⁻¹
T_m = 918°K
ΔH_m^o = [5.5 ± 1.0] kcal. mole⁻¹
T_b = 920°K
ΔH_v^o = [22.0 ± 4.0] kcal. mole⁻¹

Heat of Formation. Calculated from ΔH_f^o (crystal).

Heat Capacity and Entropy. C_p was estimated by analogy with mercuric iodide and bromide. A glass type transition was assumed at 613°K below which the heat capacity was that of HgF₂(crystal). The entropy was calculated from S°(crystal) and the estimated ΔH_m and heat capacities of crystal and liquid.

Fusion and Vaporization. T_m was given by O. Ruff and G. Bahlon, Ber. 51, 1752 (1918). T_b, ΔH_m, and ΔH_v were all taken from L. Brewer, paper 7, National Nuclear Energy Series 4-19B "Thermodynamics" McGraw-Hill (1950).

(IDEAL GAS)

MERCURY DIFLUORIDE (HgF₂)

MOL. WT. = 238.61

Point Group D_{∞h}
ΔH°_f 298.15 = [-70.2 ± 10.0] kcal mole⁻¹
S°_{298.15} = 63.545 cal deg⁻¹ mole⁻¹
Vibrational Levels and Multiplicities

ω, cm⁻¹
[600] (1)
[120] (2)
[593] (1)

Hg-F distance = [1.96] Å

Moment of Inertia = [12.118 × 10⁻³⁹] g cm² σ = 2

Heat of Formation

Estimated by comparison with the other gaseous mercuric halides and with the crystalline mercurous mercuric fluorides.

Heat Capacity and Entropy

Vibrational constants were estimated by analogy with the other mercuric halides and the mercurous halides. The bond length was estimated by assuming the mercurous bond to be 0.965 of the mercuric bond by analogy with the mercury chlorides.

 $S^\circ_{298.15} = [38.4 \pm 2.0] \text{ cal. deg}^{-1} \text{ mole}^{-1}$
 $T_{\text{sub}} = [918]^\circ\text{K (decomp.)}$

Heat of Formation. A value of $\Delta H^\circ_{298.15}$ was obtained from the cell measurements of G. G. Koerber and T. de Vries, J. Amer. Chem. Soc. 71, 5000 (1949). This was combined with ΔS°_f from the estimated entropy.

Heat Capacity and Entropy. The heat capacity was estimated by comparison with mercurous chloride. The entropy was estimated by comparison with the other mercurous and mercuric halides and use of additive entropy constants for the halogens from K. K. Kelley (Private Communication, 1960).

Sublimation. Sublimation with decomposition to $\text{Hg}_2(\text{g})$ and $\text{HF}_2(\text{g})$ was assumed at 940°K from the free energy change of the reaction.

Rotational Constant: B₀ = {0.094} cm⁻¹
σ = 2

Heat of Formation

The heat of formation is estimated from three calculated values. The methods of calculation are described as follows. In a manner analogous to LiF₂(g), the first reaction considered is KF(g) + F⁻(g) = KF₂⁻(g) and the ΔH_f^o₂₉₈(KF₂⁻, g) is evaluated to be between 0 and 1/2(-50) = -25 kcal/mol (see LiF₂⁻(g) table for details), yielding from JANAF Tables.

The second reaction employed for estimation is K₂F₂(g) = KF₂⁻(g) + K⁺(g). The enthalpy change of this reaction is calculated as ΔH_r^o₂₉₈ = 1/2(50.0) + 138.8 = 163.8 kcal/mol where the KF₂⁻ ion is considered to be converted from K₂F₂(g) by breaking one of the two dimer association bonds (ΔH_r^o₂₉₈ = 50.0 kcal/mol) and one K⁺-F⁻ ionic bond (ΔH_r^o₂₉₈ = 138.8 kcal/mol). Using ΔH_f^o₂₉₈ = -206.2 and 122.9 kcal/mol for K₂F₂(g) and K⁺(g), we obtain the heat of formation for KF₂⁻(g) as -165 kcal/mol.

Based on an assumption that the electron affinity of KF₂(g) is similar to that of F (see LiF₂⁻(g) table for details), i.e. ΔH_r^o₂₉₈ = 83.5 kcal/mol (1) for the reaction KF₂⁻(g) = KF₂(g) + e⁻(g), we derive ΔH_f^o₂₉₈(KF₂⁻, g) = -167.7 kcal/mol. The ΔH_f^o₂₉₈ for KF₂(g) is calculated as -84.2 kcal/mol from the value ΔH_r^o₂₉₈ = 143.3 kcal/mol for the reaction K₂F₂(g) = KF₂(g) + K(g) where the ΔH_r^o₂₉₈ value is calculated as the sum of two enthalpy changes, i.e. half of the heat of dimer dissociation into two monomers or 1/2(50.0) = 25.0 kcal/mol, and the heat of dissociation of KF(g) or 118.3 kcal/mol. The value of ΔH_f^o₂₉₈ for KF₂⁻(g) is tentatively adopted as -166 ± 10 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion given by Walsh (2) that molecules with not more than 16 valency electrons are linear in their ground states. The K-F bond distance is taken to be the same as that of KF(g) reported by Veazey and Gordy (3). The vibrational frequencies are estimated from the vibrational frequency of KF(g) using the method suggested by Herzberg (4). The moment of inertia is 2.971 x 10⁻³⁸ g cm². The enthalpy at 0°K is -1.293 kcal/mol.

Bond Distance: K-F = 2.2 Å

Bond Angles: F-K-F = [90°] K-F-K = [90°]

Product of the Moments of Inertia: $I_A I_B I_C = [2.240 \times 10^{-113}] \text{ g}^3 \text{ cm}^6$

Heat of Formation

The equilibrium constants (K_c) for the reaction K₂F₂(g) = 2KF(g), in the temperature range 974-1052°K, were determined by Eisenstadt, Rothberg, and Kusch (2). Although the reported absolute values of the vapor pressures of KF(g) are not adopted for evaluation, the reported K_c values are used to calculate the enthalpy change (ΔH_{298}°) for the above reaction. The second law and third law values of ΔH_{298}° are derived as 51.0 ± 1.6 and 50.0 kcal/mol, respectively. Based on the third law ΔH_{298}° and $\Delta H_{298}^\circ(\text{KF}, \text{g}) = -78.1$ kcal/mol, we obtain $\Delta H_f^\circ = -206.2$ kcal/mol for K₂F₂(g) which is tentatively adopted.

Heat Capacity and Enthalpy

The molecular structure and K-F bond distance were determined by Akishin and Rambidi (2), using electron diffraction with sector microphotometry. The bond angles are estimated by comparison with other alkali halide dimers. The vibrational frequencies are taken from Berkowitz (3) which were calculated based on an ionic model. The three principal moments of inertia are: $I_A = 3.1423 \times 10^{-38}$, $I_B = 1.5267 \times 10^{-38}$, and $I_C = 4.6690 \times 10^{-38} \text{ g cm}^2$.

Heat of Formation

Due to lack of thermal data, the heat of formation for LiF₂⁻(g) is arbitrarily selected from the following three estimated values. For the reaction (1) LiF(g) + F⁻(g) = LiF₂⁻(g), we expect the enthalpy change would be between 0 to -31 kcal/mol. Comparison with the other molecules like CO₂, BO₂, BrF₂, etc. having 16 valence electrons leads us to assume that the isoelectronic molecule LiF₂⁻ should also be quite stable. This indicates that reaction (1) is favorable or ΔHr₂₉₈ is negative. However, the Li-F bond strength is expected to be weaker than half of the two ionic bonds between Li⁺ and F⁻ in Li₂F molecule (see Li₂F₂ (g) table for the molecular structure). In other words, the ΔHr₂₉₈ value of reaction (1) is less negative than half of the heat of dimerization (-62.4 kcal/mol). Incorporating ΔHr₂₉₈ = 0 and -31 kcal/mol, respectively, for reaction (1), with ΔHf₂₉₈^o = -81.45 and -62.2 kcal/mol for LiF(g) and F⁻(g), we derived the corresponding values for ΔHf₂₉₈^o(LiF₂⁻, g) as -144 and -175 kcal/mol, which are the upper and lower limits.

The electron affinities of Li and F atoms are reported as 0.7 and 3.448 eV, respectively, by Backett and Cassidy (1). From this data we estimate that the electron affinity of LiF₂⁻(g) should be closer to that of F atom than to that of Li. Assuming ΔHr₂₉₈^o = electron affinity of F atom = 83.5 kcal/mol for the reaction LiF₂⁻(g) = LiF(g) + F⁻(g), we obtain the heat of formation for LiF₂⁻(g) as -177.3 kcal/mol. The ΔHf₂₉₈^o(LiF₂⁻, g) used for calculation is derived from an estimated ΔHr₂₉₈^o = 169.9 kcal/mol for the decomposition of LiF dimer or LiF₂⁻(g) = LiF₂(g) + Li(g) as the sum of two enthalpy changes, namely, half of the heat of dissociation of the dimer and the heat of dissociation of the monomer.

The third estimated value for the heat of formation of LiF₂⁻(g) is calculated as follows. Based on the two heats of reaction, i.e. ΔHr₂₉₈^o = 62.4 kcal/mol for Li₂F₂(g) = LiF(g), and ΔHr₂₉₈^o = 183.5 kcal/mol for LiF(g) + F⁻(g), we assume the enthalpy change of the reaction Li₂F₂(g) = LiF₂⁻(g) + Li⁺(g) to be 1/2(62.4) + 183.5 = 714.7 kcal/mol. In other words, we consider the LiF₂⁻(g) molecule is formed by breaking half of the dimer dissociation bonds and one monomer dissociation bond to produce two ions. Using ΔHf₂₉₈^o = -225.33 and 164.24 kcal/mol for Li₂F₂(g) and Li⁺(g), we evaluate ΔHf₂₉₈^o(LiF₂⁻, g) = -174.9 kcal/mol.

From the above three estimated values, we tentatively choose ΔHf₂₉₈^o(LiF₂⁻, g) as -170 ± 15 kcal/mol.

Heat Capacity and Entropy

According to A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953), molecules with not more than 16 valence electrons are linear in their ground states. Since LiF₂⁻(g) has 16 valence electrons, we assume its molecular structure is linear. The Li-F bond distance is estimated by comparison with that of LiF(g) reported by Wharton et al. (2). The vibrational frequencies are estimated from those of the isoelectronic gaseous molecules, CO₂ and BeF₂. The moment of inertia is 1.555 × 10⁻³⁸ g cm². The enthalpy at 0°K is -2.653 kcal/mol.

Heat of Formation

The heat of formation (ΔH_f°) is calculated based on the adopted value $\Delta H_f^\circ(\text{1000}) = 61.4$ kcal/mol for the reaction $\text{Li}_2\text{F}_2(\text{g}) = 2\text{LiF}(\text{g})$ which is consistent with the literature values listed in the table below. Due to lack of knowledge of the fragmentation patterns, the relative ionization cross sections of the ionic species formed in the mass spectrometer, and the molecular constants of the LiF polymers, the evaluation of equilibrium constants used to calculate ΔH_f° involves considerable uncertainty. In order to solve this problem more research work seems necessary.

Heat Capacity and Entropy

The molecular structure of Li₂F₂(g) was determined as D_{2h} by Buchler et al. (12), using electric deflection and mass spectrometric detection. Akishin and Rambidi (1) studied the structure of Li₂F₂(g) by electron deflection with sector microphotography and assigned the bond distances of Li-F and F-F which are adopted. Evidence for a matrix stabilized linear structure of Li₂F₂ has been obtained by extending the spectral measurements for matrix isolated lithium fluoride into the far infrared region by Redington (8) and Abramowitz et al. (9).

Klemperer and Norris (10) observed two infrared-active vibrational frequencies, 640 and 460 cm⁻¹, and assigned them as $\nu_6(\text{D}_{2h})$ and $\nu_5(\text{D}_{2h})$. The infrared absorption spectra of lithium fluoride monomer and dimer isolated in solid inert gas matrices were investigated by Linevsky (11), Shelton and Pitzer (13), and Schlick and Schnepf (14). Redington (8) obtained infrared spectra of LiF species suspended in solid Ne, O₂, CO, and CH₄ at liquid-helium temperature. The observed solvent shifts for LiF and Li₂F₂ spectra exhibit several regularities. The vibrational frequencies used for calculation are those reported by Shelton (15) who re-examined the spectrum of LiF species over the range 200 - 4000 cm⁻¹, using sample purity of 99.3%. The saturated vapor was isolated at 900°C and the superheated unsaturated vapor at 1200°C. A variety of deposition rates and matrix dilutions was tried. Based on the frequencies assigned to the isotopic species, the vibrational frequencies of the natural isotopic Li₂F₂(g) are calculated. It appears that the vibrational frequencies calculated on the basis of the potential function for an ionic model by Berkowitz (16) are too low.

The three principal moments of inertia are: $I_A = 2.3970 \times 10^{-39}$, $I_B = 1.1244 \times 10^{-38}$ and $I_C = 1.3641 \times 10^{-38} \text{ g cm}^2$.

Dec. 31, 1960; June 30, 1964; Mar. 31, 1966

$$S_{298.15}^{\circ} = 13.68 \pm 0.07 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1536^{\circ}\text{K.}$$

$$\Delta H_f^{\circ} 0 = -267.8 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{\circ} 298.15 = -268.7 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{\circ} = 13.90 \text{ kcal. mole}^{-1}$$

$$\Delta H_g^{\circ} 298.15 = 95.5 \pm 1.5 \text{ kcal. mole}^{-1}$$

Heat of Formation.

The value of $\Delta H_f^{\circ} 298.15$ for $\text{MgF}_2(\text{c})$ was obtained from E. Rudzitis and W. N. Hubbard, Argonne National Laboratory, Argonne, Illinois, private communication, dated June 18, 1964. This value was determined by fluorine bomb calorimetry which is considered as comparatively the best method available at the present time. The heats of reaction involving $\text{MgF}_2(\text{c})$ were measured by many early investigators. However, the $\Delta H_f^{\circ} 298.15(\text{MgF}_2, \text{c})$ values derived are in reasonable agreement. The results are presented as follows.

Investigator	Chemical Reaction	$\Delta H_f^{\circ} 298.15^{\circ}$, kcal. mole ⁻¹	$\Delta H_f^{\circ} 298.15^{\circ}$, kcal. mole ⁻¹
Domange (1)	$\text{MgF}_2(\text{c}) + \text{H}_2\text{O}(\text{g}) \rightarrow 2\text{HF}(\text{g}) + \text{MgO}(\text{c})$	+51.76 ± 1.2 (1)	-267.3 ± 1.3
Wartenberg (2)	$\text{Mg}(\text{c}) + 2(\text{HF} \cdot 80\text{H}_2\text{O}) \rightarrow \text{MgF}_2(\text{c}) + \text{H}_2(\text{g}) + 160\text{H}_2\text{O}(\text{l})$	-109.5 ± 0.7	-262.1 ± 0.8
Torgeson, et al. (3)	$\text{Mg}(\text{OH})_2(\text{c}) + 2\text{HF}(\text{sol.}) \rightarrow \text{MgF}_2(\text{c}) + 2\text{H}_2\text{O}(\text{l})$	-29.09	-266.5 ± 0.8
Gross, et al. (4)	$\text{Mg}(\text{c}) + \text{PbF}_2(\text{c}) \rightarrow \text{MgF}_2(\text{c}) + \text{Pb}(\text{c})$	-109.5 ± 1.5	-269.1 ± 1.8
(1) L. Domange, Ann. chim. phys. 7(11)225 (1937). The ΔH_f° value was calculated by the third law method.

Heat Capacity and Entropy.

The low temperature heat capacities, $54.22-296.5^{\circ}\text{K.}$, were measured by S. S. Todd, J. Am. Chem. Soc. 71, 4115 (1949). The high temperature heat capacities, $298-1536^{\circ}\text{K.}$, were obtained from the heat content measurements determined by B. P. Naylor, J. Am. Chem. Soc. 67, 150 (1945). These two sets of data were joined smoothly at 298°K. $S_{298.15}$ was obtained from C_p data reported by S. S. Todd, loc. cit., using $S_{298.15}^{\circ}(\text{extrap.}) = 0.537 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

T_m and ΔH_m° were taken from B. P. Naylor, loc. cit.

Heat of Sublimation.

The vapor pressure of $\text{MgF}_2(\text{c})$ has been measured by seven investigators. Using the reported data, the respective $\Delta H_g^{\circ} 298.15$ for $\text{MgF}_2(\text{c})$ were calculated (see $\text{MgF}_2(\text{g})$ table for detail). The adopted value was selected to be $95.5 \pm 1.5 \text{ kcal. mole}^{-1}$.

$$\Delta H_f^\circ 298.15 = -259.557 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^\circ = 13.90 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^\circ = [63.48] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^\circ = 15.290 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1536^\circ \text{K.}$$

$$T_b = [2499]^\circ \text{K.}$$

Heat of Formation.

$\Delta H_f^\circ 298.15(1)$ was obtained from $\Delta H_f^\circ 298.15(c)$ by adding ΔH_m° and the difference between $H_m^\circ - H_{298.15}^\circ$ for crystal and liquid.

Heat Capacity and Entropy.

Heat capacity (1691-1800°K.) was reported by B. F. Naylor, J. Am. Chem. Soc. 67, 150 (1945). The same value was used for other temperatures. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and ΔH_m° were obtained from B. F. Naylor, loc. cit.

Vaporization Data.

T_b was obtained from equilibrium calculation between the species $\text{MgF}_2(1)$, $\text{MgF}_2(g)$, and $(\text{MgF}_2)_2(g)$, i.e., the temperature at which the sum of the partial pressures of $\text{MgF}_2(g)$ and $(\text{MgF}_2)_2(g)$ equals one atmosphere. From the difference between the heats of formation of $\text{MgF}_2(1)$ and $\text{MgF}_2(g)$ at the boiling point, the heat of vaporization was calculated. At the boiling point the amount of dimeric species is negligible in comparison with that of the monomeric species.

Heat of Formation

The vapor pressure of MgF₂(g) over MgF₂(c) and MgF₂(l) has been measured by many investigators using different methods. Based on the reported vapor pressure data, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

*a = Monometric method; b = Knudsen effusion method; and c = Torsion effusion method

1 O. Ruff and L. LeBoucher, Z. anorg. allgem. Chem. **219**, 378 (1934).2 K. O. Quenther, Oesterr. Ber. **31**, 9 (1959).3 R. R. Hammer, Ph.D. Thesis, University of California, 1961. Also see R. R. Hammer and J. A. Peek, J. Am. Ceram. Soc. **47**, 284 (1964).4 J. Berkowitz and J. R. Marquart, J. Chem. Phys. **37**, 1853 (1962). The value, 91.38 kcal. mole⁻¹, was converted from the reported value 88 kcal. mole⁻¹ at 1350°K.5 M. A. Greenbaum, R. C. McRae, and M. Farber, J. Phys. Chem. **68**, 985 (1964), whose reported $\Delta H_f^{298.15}$ value was derived using different values of free energy functions for MgF₂(c) and MgF₂(g) from those used here.6 H. Hildenbrand, et al., J. Phys. Chem. **68**, 985 (1964), whose reported $\Delta H_f^{298.15}$ value was derived from the heat of sublimation of MgF₂(c) and MgF₂(g) from those used here.7 J. W. Green, G. D. Blue, T. C. Ehlers, and J. L. Margrave, J. Chem. Phys. **41**, 2245 (1964).

When vapor pressure data were determined above melting point, 1536°K., the heat of sublimation was derived from the heat of vaporization obtained incorporating heat of melting. All data were carefully examined and some inconsistent vapor pressure points were discarded. The heat value of $\Delta H_f^{298.15}$ for MgF₂(c) was selected as 95.5 ± 1.5 kcal. mole⁻¹. The heat of formation for MgF₂(g) was calculated from the heats of formation and sublimation for MgF₂(c).

Heat Capacity and Entropy

The molecular structure of MgF₂(g) has been reported to be linear by A. Büchler, J. L. Steuffer and W. Klemperer, Interim Technical Report No. 7, June 30, 1964, A. D. Little, Inc., and bent by M. J. Linevsky, First Quarterly Report, Nov. 1, 1963 - Jan. 31, 1964, General Electric Company. An intensive investigation of the matrix spectrum of MgF₂(g) has been made recently by D. E. Mann and O. V. Calder, National Bureau of Standards Report 8919, July 1, 1965. The final results were presented by D. E. Mann at the ICRP Working Group on Thermochemistry meeting on Mar. 17, 1968. The vibrational frequencies, bent structure and bond angle were confirmed by use of isotopic substitution, and were adopted here. The Mg-F bond distance was reported by P. A. Akishin, V. P. Spiridonov, O. A. Sobolev and V. A. Naumov, Zh. Fiz. Khim. **31**, 463 (1957). The three principal moments of inertia are: $I_A = 5.1680 \times 10^{-40}$, $I_B = 1.8442 \times 10^{-38}$ and $I_C = 1.8959 \times 10^{-38} \text{ g. cm.}^2$

Bond Angle: F-N-N = 114.5 ± 0.5°

Product of the Moments of Inertia: I_AI_BI_C = 6.53821 X 10⁻¹¹⁵ g.³ cm.⁶

σ = 2

Heat of Formation.

The heat of formation was derived from the heat of reaction N₂F₂(g) + 8/5 NH₃(g) = 2NH₄F(c) + 4/5 N₂(g) which was measured calorimetrically by G. T. Armstrong and S. Marantz¹. There are two isomers, the trans and the active form of difluorodiazine. The heats of formation were determined to be 19.4 and 16.4 kcal. mole⁻¹ for the trans and the active isomers respectively. The active form of N₂F₂ has been interpreted here as the cis isomer which will be discussed later. The heat of isomerization has also been reported as 3.0 kcal. mole⁻¹ by Armstrong and Marantz. The value, ΔH_f^o 298 (cis N₂F₂, g) = 16.4 kcal. mole⁻¹, is adopted in the tabulation.

A. V. Pankratov et al.² have measured the enthalpy of reaction N₂F₂(g) + 3KI = 2KF + N₂ + KI₃ in acidic solution (pH = 3), and reported ΔH_f^o 298 (active N₂F₂, g) = 25.3 ± 2.0 kcal. mole⁻¹.

The "heat of isomerization" has been reported as 27.5 ± 5.0 kcal. mole⁻¹ by C. B. Colburn et al.⁹. The derivation of this value is unknown. The authors observed three values of the equilibrium constant for the isomerization reaction. Third law analysis of their data gives ΔH_f^o 298 = 2.52 ± 0.05 kcal. mole⁻¹ for the reaction cis N₂F₂(g) → trans N₂F₂(g) which is in good agreement with Armstrong and Sidney's data.

Heat Capacity and Entropy.

Although the infrared spectrum^{7,8} of the active form of N₂F₂(g) has been interpreted as favoring the 1,1-difluorodiazine over the cis-configuration^{3,4}, n.m.r.⁵ and microwave studies definitely indicate the latter. The vibrational frequencies⁷ previously assigned to the 1,1-difluorodiazine have been adopted here for the cis isomer. The selected bond distances and angle were taken from the isotopic nitrogen microwave studies⁶. The principal moments of inertia were: I_A = 4.2438 X 10⁻³⁹, I_B = 10.5129 X 10⁻³⁹ and I_C = 14.7567 X 10⁻³⁹ g. cm.²

See the trans N₂F₂(g) table for the comparison of the different physical properties between trans and cis isomers.

Heat of Formation.

G. T. Armstrong and S. Marantz, J. Chem. Phys. **39**, 169 (1963) have measured calorimetrically the enthalpy of reaction N₂F₂(g) + 8/5 NH₃(g) = 2NH₄F(c) + 4/5 N₂(g), and reported ΔH_f⁰ 298 (trans N₂F₂, g) = 19.4 ± 1.2 kcal. mole⁻¹ which is adopted in this tabulation.

Heat Capacity and Entropy.

The bond distances and bond angle were obtained from S. H. Bauer, J. Am. Chem. Soc. **69**, 3104 (1947), by electron diffraction. The fundamental vibrational frequencies were obtained from R. H. Sanborn, J. Chem. Phys. **33**, 1855 (1960) by infrared spectroscopy. The three principal moments of inertia are I_A = 0.919 × 10⁻³⁹, I_B = 21.2433 × 10⁻³⁹ and I_C = 22.1823 × 10⁻³⁹ g. cm.²

As pointed out by R. Ettinger, F. A. Johnson and C. B. Colburn, J. Chem. Phys. **34**, 2187 (1961), the trans N₂F₂ is the less active isomer which is different from the active isomer by its (1) vapor pressure (2) boiling point (3) heat of vaporization (4) critical temperature (5) melting point (6) mass spectral cracking pattern (7) NMR spectrum (8) infrared spectrum (9) heat of isomerization (10) reactivity with mercury and glass.

Heat of Formation

The heat of formation for $\text{NaF}_2^-(g)$ is estimated from three calculated values. The methods of calculation are described as follows. The first reaction we take into consideration is $\text{NaF}(g) + \text{F}^-(g) = \text{NaF}_2^-(g)$. In a manner analogous to $\text{LiF}_2^-(g)$ molecule (see $\text{LiF}_2^-(g)$ table for details), we assume $\text{NaF}_2^-(g)$ is stable and ΔH_f° for the reaction $\text{NaF}(g) + \text{F}^-(g) = \text{NaF}_2^-(g)$ is somewhere between 0 to 172(-84) = -32 kcal/mol where the value -56 kcal/mol is the heat of dimerization. Based on $\Delta H_f^\circ = 0$ and -28 kcal/mol, respectively, with JANAF ΔH_f° values for the species involved, we obtain $\Delta H_f^\circ(\text{NaF}_2^-, g) = -112$ and -164 kcal/mol as the upper and lower limits.

The heat of formation, calculated based on the reaction $\text{NaF}_2^-(g) = \text{NaF}_2(g) + e^-(g)$, is -165.8 kcal/mol, using ΔH_f° and $\Delta H_f^\circ(\text{NaF}_2, g)$ estimated as 83.6 and -82.3 kcal/mol, respectively. The ΔH_f° value is obtained from an assumption that the enthalpy change for removing an electron from $\text{NaF}_2^-(g)$ is comparable to that from $\text{F}^-(g)$. Due to the fact that the Na atom has smaller electronegativity (0.9) than that of the F atom (4.0), we expect that there is less possibility that the electron will associate with Na atom in the NaF_2^- molecule. Therefore we adopt the electron affinity of F(g) reported by H. O. Pritchard, Chem. Rev. 53, 529 (1963), or $\Delta H_f^\circ = 83.6$ kcal/mol for the reaction $\text{F}^-(g) = \text{F}(g) + e^-(g)$ as the ΔH_f° for $\text{NaF}_2^-(g) = \text{NaF}_2(g) + e^-(g)$. The value of ΔH_f° for $\text{NaF}_2(g)$ is calculated using the enthalpy change for the reaction $\text{Na}_2\text{F}_2(g) = \text{NaF}_2(g) + \text{Na}(g)$ as 145.8 kcal/mol which is derived from the sum of two enthalpy changes, namely, half of the ΔH_f° value for the dimer dissociation reaction $\text{Na}_2\text{F}_2(g) = 2\text{NaF}(g)$, and the ΔH_f° for the monomer dissociation reaction $\text{NaF}(g) = \text{Na}(g) + \text{F}(g)$.

Employing $\Delta H_f^\circ = 63.5$ kcal/mol for $\text{Na}_2\text{F}_2(g) = 2\text{NaF}(g)$ and 153.0 kcal/mol for $\text{NaF}(g) = \text{Na}(g) + \text{F}(g)$, we estimate $\Delta H_f^\circ = 1/2(63.5) + 153.0 = 184.7$ kcal/mol for the reaction $\text{Na}_2\text{F}_2(g) = \text{NaF}_2(g) + \text{Na}(g)$, which leads to $\Delta H_f^\circ = 163.4$ kcal/mol for $\text{NaF}_2^-(g)$. For all calculations the ΔH_f° values of the chemical species involved are taken from JANAF Thermochemical Tables.

The value of ΔH_f° for $\text{NaF}_2^-(g)$ is tentatively adopted as -160 $\pm$ 10 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion by A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953) that molecules with not more than 16 valence electrons are linear in their ground state. The Na-F bond distance is estimated by comparison with that of $\text{NaF}(g)$ reported by S. E. Veazey and W. Gordy, Phys. Rev. 138, A1303 (1965). The vibrational frequencies are estimated from those for the isoelectronic molecule $\text{SiO}_2(g)$. The moment of inertia is $2.350 \times 10^{-38} \text{ g cm}^2$. The enthalpy at 0°K is -3.117 kcal/mol.

Heat of Formation

Although the absolute values of the vapor pressure measurements are not used for evaluation, the ratios of the numbers of dimeric and monomeric NaF molecules that effuse from the oven at the temperatures 1115–1191°K determined by Eisenstadt, Rothberg, and Kusch (1) by use of the electron-beam velocity-selector method are used. Based on the reported equilibrium data we evaluate the enthalpy change of the reaction (A) $\text{Na}_2\text{F}_2(\text{g}) = 2\text{NaF}(\text{g})$ by the second and third law methods. The results are presented in the table below.

Porter and Schoonmaker (2) analyzed the vapor effusing from a Knudsen cell at 1121°K mass spectrometrically and derived the partial pressures of NaF(g) and Na₂F₂(g) at that temperature. Using these reported partial pressures we calculate, by the third law method, the value $\Delta H_{298}^\circ = 64.1 \text{ kcal/mol}$ for reaction (A).

Sidorov et al. (3) studied the NaF–ZrF₄ system by the mass spectrometric method and derived the partial pressures of NaF(g) and Na₂F₂(g) as a function of composition and temperature. Employing the data points reported at 1074° and 1167°K we obtain the third law value $\Delta H_{298}^\circ = 62.0 \pm 1.6 \text{ kcal/mol}$ for the same reaction.

The ΔH_{298}° (Na₂F₂, g) is calculated based on the adopted third law value $\Delta H_{298}^\circ = 63.5 \text{ kcal/mol}$ for the reaction $\text{Na}_2\text{F}_2(\text{g}) = 2\text{NaF}(\text{g})$, using ΔH_f° (NaF, g) = –69.5 kcal/mol. Brewer and Brackett (3) reported $\Delta H_{1000}^\circ = 56.9 \text{ kcal/mol}$ for the above reaction. According to our tables the ΔH_{1000}° value is 62.5 kcal/mol.

Heat Capacity and Entropy

The Na₂F₂ molecule is assumed to have a rhombic structure with D_{2h} (h) symmetry (4, 5). The Na-F bond distance is reported by Akishin and Rambidi (5), who studied the molecular structure of alkali halide vapors by electron diffraction with sector microphotometry. The bond angle is estimated by comparison with those of the other alkali halides. Berkowitz (4, 5) has calculated the vibration frequencies of Na₂F₂ based on an ionic model. By comparison of the calculated frequencies of Li₂F₂ (6) with those of the observed ones (see Li₂F₂(g) table for details) we reestimate the vibrational frequencies for Na₂F₂(g) to be higher than the ones reported by Berkowitz (5). Bauer et al. (7) used a pseudo-electrostatic model, similar to the one suggested by O'Konski and Higuchi (8), to calculate the entropies of dimerization for a number of gaseous alkali halides and estimated the six vibrational frequencies as 477, 318, 291, 477, 291, and 291 cm^{–1}. Bauer et al. calculated $\Delta S_{1146}^\circ = -32.5 \text{ eu}$ for the reaction $2\text{NaF}(\text{g}) = \text{Na}_2\text{F}_2(\text{g})$, in reasonable agreement with the value –33.5 eu which is derived using JANAF Silus values for NaF(g) and Na₂F₂(g).

The three principal moments of inertia are: $I_A = 1.399 \times 10^{-38}$, $I_B = 1.422 \times 10^{-38}$, and $I_C = 2.821 \times 10^{-38} \text{ g cm}^2$.

Heat of Formation.

From the enthalpy change, $\Delta H_f^\circ 298.15 = 131.03$ kcal. mole⁻¹, for the reaction SO₂P₂(g) = SO₂(g) + O(g), the value of $\Delta H_f^\circ 298.15$ for SO₂(g) was calculated to be -133.5 kcal. mole⁻¹, using $\Delta H_f^\circ 298.15 = -203.0$ and 59.56 kcal. mole⁻¹ for SO₂P₂(g) and O(g), respectively. The value of $\Delta H_f^\circ 298.15$ was assumed to be the same as that for the reaction SO₂(g) = SO(g) + O(g) which was calculated based on $\Delta H_f^\circ 298.15 = -70.95$, 0.52 and 59.56 kcal. mole⁻¹ for SO₂(g), SO(g) and O(g), respectively. Using $\Delta H_f^\circ 298.15 = 127.86$ kcal. mole⁻¹ for the reaction SO₂P₂(g) = SO₂(g) + O(g), the value of $\Delta H_f^\circ 298.15$ (SOF₂, g) was evaluated as -136.7 kcal. mole⁻¹ where the $\Delta H_f^\circ 298.15$ value was assumed to be the same as the S-O bond energy in SO₂(g). The value of $\Delta H_f^\circ 298.15$ (SOF₂, g) adopted is -135 ± 10 kcal. mole⁻¹.

Heat Capacity and Entropy.

The bond distances and angles were obtained from R. C. Ferguson, J. Am. Chem. Soc. 76, 850 (1954). The vibrational frequencies were taken from R. J. Gillespie and E. A. Robinson, Can. J. Chem. 39, 2171 (1961). The assignment of these vibrational frequencies was based on the previous measurements of the infrared and Raman spectra reported by J. K. O'Leane and M. K. Wilson, J. Chem. Phys. 23, 1313 (1955), P. Bender and J. M. Wood, J. Chem. Phys. 23, 1316 (1955) and D. M. Vost, Proc. Indian Acad. Sci. B, 333 (1958). The fundamental assignment reported by J. K. O'Leane and M. K. Wilson, loc. cit., was 1333, 808, 530, (410), 748 and 390 cm.⁻¹. The three principal moments of inertia are: I_A = 1.0034 X 10⁻³⁸, I_B = 9.7421 X 10⁻³⁹ and I_C = 1.6935 X 10⁻³⁸ g. cm.².

The heat capacities of thionyl fluoride (SOF₂) have been measured, from 12° to 230°K., by E. L. Pace and B. F. Turnbull, J. Chem. Phys. 43, 1953 (1965), for a sample of 99.97% mole % purity. Incorporating them with the measured $\Delta H_f^\circ 1.506$ kcal. mole⁻¹ at T₀ = 143.25°K., and $\Delta H_f^\circ 5.091$ kcal. mole⁻¹ at T₀ = 228.84°K., which was derived from the measured vapor pressure of SOF₂(l), the entropy of SOF₂(g) at 228.84°K. was evaluated as 63.56 e.u. This value is in excellent agreement with the corresponding value, 63.522 e.u., calculated using the adopted molecular constants. This indicates the fact that the molecular constants used for the calculation of the tabulated thermodynamic functions are adequate. Hence the new vibrational frequencies suggested by Pace and Turnbull, loc. cit., were not used.

TITANIUM OXIDE DIFLUORIDE (TiOF₂)

(IDEAL GAS)

MOL. WT. = 101.9

Point Group [C_{2v}]
 $\Delta H_f^o = [-220] \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = [68.016] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^o 298.15 = [-221] \text{ kcal. mole}^{-1}$
 Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω , cm ⁻¹	ω , cm ⁻¹
[553] (1)	[718] (1)
[888] (1)	[300] (1)
[350] (1)	[452] (1)

ε = 2

Bond Distances: Ti-O = [1.62] Å Ti-F = [1.74] Å

Bond Angle: O-Ti-F = [120°]

Product of Moments of Inertia: $I_A I_B I_C = [4.34 \times 10^{-114}] \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

ΔH_f^o O was estimated as -220 kcal. mole⁻¹ by J. S. Gordon, Astrostatum, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. $\Delta H_f^o 298.15$ was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. The principal moments of inertia are:
 $I_A = 14.3274 \times 10^{-39} \text{ g. cm.}^2$, $I_B = 11.6632 \times 10^{-39} \text{ g. cm.}^2$, and $I_C = 25.9907 \times 10^{-39} \text{ g. cm.}^2$

Sulfuryl Difluoride (SO₂F₂)
(Ideal Gas) Mol. Wt. = 102.066

F₂O₂S

MOL. WT. = 102.066

(IDEAL GAS)

SULFURYL DIFLUORIDE (SO₂F₂)

Point Group C_{2v}
ΔH_f⁰ = -203 kcal. mole⁻¹
S_{298.15} = 68.883 cal. deg.⁻¹ mole⁻¹
ΔH_f⁰ 298.15 = -205 kcal. mole⁻¹
Oscillator Strength Multiplicity = [1]

Vibrational Frequencies and Degeneracies			
ν, cm. ⁻¹	ν, cm. ⁻¹	ν, cm. ⁻¹	ν, cm. ⁻¹
1269 (1)	274 (1)	539 (1)	
848 (1)	360 (1)	885 (1)	
553 (1)	1502 (1)	386 (1)	

Bond Distance: S-O = 1.405 ± 0.003 Å S-F = 1.530 ± 0.003 Å
Bond Angle: O-S-O = 123° 58' ± 12' F-S-F = 98° 7' ± 10' σ⁻ = 2
Product of the Moments of Inertia: I_AI_BI_C = 4.4673 × 10⁻¹¹⁴ g.³ cm.⁶

Heat of Formation.

The heat of formation was reported by R. M. Reese, V. H. Dibeler and J. L. Franklin, J. Chem. Phys. 29, 880 (1958). The value was calculated from the appearance potential of the SO₂⁺ ion obtained from electron impact studies of SO₂ and SO₂P₂.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from O. R. Hunt, and M. K. Wilson, Spectrochim. Acta, 16, 570 (1960). The bond distances and bond angles were reported by D. R. Lide, Jr., D. E. Mann, and R. M. Friarom, J. Chem. Phys., 26, 734 (1957). The entropy of sulfuryl fluoride gas has been calculated from the calorimetric data and the third law of thermodynamics to be 62.66 cal. deg.⁻¹ mole⁻¹ at 217.78°K. by P. J. Bockhoff, R. V. Petrella, and E. L. Pace, J. Chem. Phys. 32, 799 (1960). The discrepancy between entropy value calculated from calorimetric data and that calculated from molecular and spectroscopic data (1 atm., 217.78°K) is attributed to randomness in the solid at 0°K by P. J. Bockhoff and E. L. Pace, J. Chem. Phys. 34, 3502 (1962). The vibrational frequencies reported by M. D. Perkins and M. Kent Wilson, J. Chem. Phys. 20, 1791 (1952) were 1269 (1), 848 (1), 544 (1), [500] (1), [385] (1), 1502 (1), 553 (1), 885 (1), and 539 (1) cm.⁻¹. The three principal moments of inertia are: 1.6567 × 10⁻³⁸, 1.6567 × 10⁻³⁸, and 1.6349 × 10⁻³⁸ g. cm.².

Phosphorus Difluoride (PF₂) (Ideal Gas)

Mol. Wt. = 68.975

ΔH_f 298.15 = [-105 ± 15] kcal. mole⁻¹

S_{298.15} = [62.2 ± 3] cal. deg.⁻¹ mole⁻¹

Ground State Multiplicity = 2

Point Group C_{2v}

Vibrational Levels and Multiplicities
(U, cm.⁻¹)
(376) (1)
(775) (1)
(890) (1)

I_AI_BI_C = [1.9059 × 10⁻¹¹⁵] g.³ cm.⁶ σ = 2

Heat of Formation. ΔH_f 298.15 was estimated by C. B. Henderson and R. S. Scheffer, "Atlantic Research Corp., Alexandria, Virginia, "Survey of Thermochemical Data," January, 1960. For their estimation they assumed certain bond energies for the dissociation of PF₃(g). Bond one was assumed 20% greater than bond two and three which were assumed to be equal. ΔH_f 298.18 was corrected for the change in phosphorus reference state (white α → red V).

Heat Capacity and Entropy. Molecular constants and vibrational levels were estimated by J. S. Gordon, Thiokol Chemical Corp., Reaction Motors Division, Denver, N. J., "Thermodynamic Data for Combustion Products," January, 1960.

$$\Delta H_{\text{f}}^{\circ} = [0.61] \text{ kcal/mol}$$

$$\Delta H_{\text{f}}^{\circ} = 0.65 \text{ kcal/mol}$$

$$\Delta H_{\text{m}}^{\circ} = 2.98 \text{ kcal/mol}$$

$$\Delta H_{298.15}^{\circ} = 88.5 \text{ kcal/mol}$$

Heat of Formation

The heats of formation at 298.15°K derived from the enthalpy changes of different chemical reactions are listed below. The adopted one is the average of the last three $\Delta H_{298.15}^{\circ}$ values, which is also in reasonable agreement with the $\Delta H_{298.15}^{\circ}$ values evaluated from (1) and (5).

Reference	Chemical Reaction	$\Delta H_{298.15}^{\circ}$ Kcal/mol	$\Delta H_{298.15}^{\circ}$ Kcal/mol
1	$\text{PbF}_2(\text{c}) + \text{H}_2(\text{g}) = \text{Pb}(\text{l}) + 2 \text{HF}(\text{g})$	32.0 ± 0.56*	-161.3 ± 0.6
2	$\text{PbF}_2(\text{c}) + \text{H}_2\text{O}(\text{g}) = \text{PbO}(\text{c}) + 2 \text{HF}(\text{g})$	29.6 ± 2.1**	-154.5 ± 4.0

4	$\text{PbO}(\text{c}) + 2 \text{HF}(40\% \text{ aq}) = \text{PbF}_2(\text{c}) + \text{H}_2\text{O}(\text{l})$	-22.9 ± 0.3	-159.0 ± 0.5
5	$\text{PbF}_2(\text{c}) + 2 \text{Na}(\text{c}) = \text{Pb}(\text{c}) + 2 \text{NaF}(\text{aq})$	-112.2 ± 0.2	-162.2 ± 0.4
6	$\text{PbF}_2(\text{c}) + \text{Mg}(\text{c}) = \text{Pb}(\text{c}) + \text{MgF}_2(\text{c})$	-109.5 ± 1.5	-159.2 ± 2.0
7	$3/2 \text{ PbF}_2(\text{c}) + \text{Al}(\text{c}) = 3/2 \text{ Pb}(\text{c}) + \text{AlF}_3(\text{c})$	-128.5 ± 0.1	-161.5 ± 1.0
8	$3/2 \text{ PbF}_2(\text{c}) + \text{Al}(\text{c}) = 3/2 \text{ Pb}(\text{c}) + \text{AlF}_3(\text{c})$	-117.7 ± 0.6	-162.1 ± 1.0
9	$1/2 \text{ PbF}_2(\text{c}) + 1/3 \text{ Al}(\text{c}) = 1/2 \text{ Pb}(\text{c}) + 1/3 \text{ AlF}_3(\text{c})$	-38.3 ± 0.8	-161.8 ± 1.0

* This is the third law value. The second law value is 32.4 ± 0.9 kcal/mol. The entropy drift is -0.5 ± 1.2 eu.
** This is the third law value. The second law value is 39.6 ± 0.7 kcal/mol. The entropy drift is -10.9 ± 0.8 eu.

Heat Capacity and Entropy

Banashek, Patsukova, and Rassonskaya (10) measured the high temperature enthalpies ($H^{\circ}-H_{298.15}^{\circ}$) for $\text{PbF}_2(\text{c})$ in the temperature range 670-1165°K. Based on their enthalpy measurements the heat capacity of $\text{PbF}_2(\text{c})$ at temperatures 725-1099°K is derived as 24.3 ± 0.2 gibbs/mol by the least square method. The heat capacities below 725°K are estimated using their reported enthalpies at 670-725°K, which are based on a mixture of β and γ , as a guide.

The $S_{298.15}^{\circ}$ is estimated to be 25 eu by the method suggested by Kubaschewski and Evans (11), and adjusted to 27 eu so that the second and third law $\Delta H_{298.15}^{\circ}$ values derived from the equilibrium data reported by Jellinek and Rudat (1) are in good agreement.

Transition Data

The transition temperatures are obtained from Banashek, Patsukova, and Rassonskaya (10). The $\beta \rightarrow \gamma$ transition at 613°K was reported as either slow or irreversible and the $\gamma \rightarrow \beta$ transition at 725°K was reversible. The polymorphism of $\text{PbF}_2(\text{c})$ has been studied by many other investigators. However, the relations between the temperature and the character of polymorphic transformation are not consistent (10).

The enthalpy difference at 725°K for $\text{PbF}_2(\gamma)$ and $\text{PbF}_2(\beta)$ is $\Delta H_{\text{f}}^{\circ}$. The value of $\Delta H_{\text{f}}^{\circ}$ is estimated such that the generated functions yield reasonable agreement among the derived $\Delta H_{298.15}^{\circ}$ values (see the above table).

Melting Data

See $\text{PbF}_2(\text{l})$ table.

Heat of Sublimation

The difference between $\Delta H_{298.15}^{\circ}$ for $\text{PbF}_2(\text{g})$ and $\text{PbF}_2(\text{c})$ is $\Delta H_{298.15}^{\circ}$.

$$\Delta H_f^{\circ} 298.15 = -158.722 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 2.98 \text{ kcal/mol}$$

$$T_m = 1099^{\circ}\text{K}$$

Heat of Formation

$\Delta H_f^{\circ} 298.15$ (l) is obtained from $\Delta H_f^{\circ} 298.15$ (c) by adding ΔH_m° and the difference between $H_m^{\circ} - H_g^{\circ} 298.15$ for crystal and liquid.

Heat Capacity and Entropy

The enthalpies ($H^{\circ} - H_g^{\circ} 15$) of PbF₂ (l) in the temperature range 1104-1165°K were determined by Banashek, Patsukova, and Rassonskaya (1). Based on their reported results the heat capacity of PbF₂ (l) is evaluated to be 24 ± 2 gibbs/mol by the least square method. This Cp value is adopted and extended to 298 and 2500°K, respectively.

The entropy ($S^{\circ} 298.15$) is calculated in a manner analogous to that of the heat of formation.

Melting Data

T_m is taken from Banashek, Patsukova, and Rassonskaya (1). The enthalpy difference at T_m for PbF₂ (l) and PbF₂ (γ) is ΔH_m° .

Other values of T_m (°K) reported are 1091 (2, 11), 1097 (3, 4, 5) and 1128 (6). Using the freezing point data of binary systems PbF₂-PbBr₂ (5), PbF₂-PbCl₂ (5, 7), PbF₂-PbI₂ (5, 8), PbF₂-PbO (9), and PbF₂-NaF (10), Kelley (3) evaluated the corresponding values of ΔH_m° (kcal/mol) as 1.70, 1.96, 3.87, and 2.47. Other reported values of ΔH_m° are 3.00 (1) and 4.16 (2) kcal/mol.

Vaporization Data

From mass spectroscopic study on the vapor species in PbF₂, Zmbov, Hastie, and Margrave (4) have shown that molten PbF₂ vaporizes partly as molecular PbF₂. There is considerable disproportionation, and at 715°K the vapor composition is approximately 66% PbF₂, 25% PbF, 21% PbF, and 71% Pb (4, 12). T_b has been reported as 1565°K (11) where the vapor is expected to be a mixture of the above species.

Bond Distance: Pb-F = 2.13 ± 0.02 Å

Bond Angle: F-Pb-F = {95°}

Product of the Moments of Inertia: I_AI_BI_C = {4.5690 × 10⁻¹¹⁴} g⁶ cm⁶ σ = 2

Heat of Formation

Vapor pressure data for PbF₂ have previously been interpreted on the assumption that PbF₂ was the only species present in the gas phase (1, 2). Zmbov, Hastie, and Margrave (3) have studied the vapor species over PbF₂(c, l) mass spectrometrically and shown that PbF₂ vaporizes only partly as molecular PbF₂ and there is considerable disproportionation. The vapor composition at 988°K is approximately 66% PbF₂, 25% PbF, and 7% Pb (3, 4). From extrapolation of the ion intensity data from 1043 to 988°K to the temperature region in which Nemeyanov and Iofa (2) measured the saturated vapor pressures of PbF₂(c), 792-988°K, by Knudsen effusion method, the partial pressure of PbF₂(c), at 988°K was calculated to be 0.0435 ± 0.005 torr. Based on this calculated vapor pressure, the heat of sublimation (ΔH_{sub})₂₉₈^o of PbF₂(c) is derived as 58.50 kcal/mol by the third law method, yielding ΔHf₂₉₈^o(PbF₂, g) = -103.3 ± 1 kcal/mol.

Due to lack of data on vapor compositions over PbF₂(c, l) at various temperatures, the total pressure measurements reported by Wartenberg and Bosc (1), using boiling point method, and those of Nemeyanov and Iofa (2) are not used for evaluation.

Heat Capacity and Entropy

The bond distance was determined by Akishin, Spiridonov, and Khodchenkova (5). The bond angle is assumed to be the same as that in PbX₂(g) where X = Cl, Br or I (6). The vibrational frequencies are calculated by valence force method (10) using force constants estimated by comparison with those for PbF (7), CaF₂ (8), HgF₂ (9), and HgF₂ (9). The value of ν₂ is in fair agreement with the value, 145 cm⁻¹, estimated by (4). The three principal moments of inertia are: I_A = 1.5559 × 10⁻³⁸, I_B = 1.1040 × 10⁻³⁸, and I_C = 2.6599 × 10⁻³⁸ g cm².

Heat of Formation

Zhobov and Margrave (1) have reported ion intensities and the corresponding equilibrium constants for the reaction Ca(g) + TiF₃(g) = CaF(g) + TiF₂(g). Second and third law analyses of their data give a second law ΔH_{f,298}° of 7.0 kcal/mol, a third law ΔH_{f,298}° of 11.76 kcal/mol and a third law drift of 3.1 ± 3.8 au. The heat of formation, ΔH_{f,298}°, of TiF₂(g) is calculated from the third law ΔH_{f,298}°, above, and the JANAF heat of formation of TiF₃(g), CaF(g) and Ca(g).

Heat Capacity and Entropy

The interatomic distances are estimated from those of TiCl₂, TiCl₄, and TiF₄. The vibrational frequencies are estimated from a valence force field model.

The electronic levels are assumed to be the same as TiCl₂(g). The levels of TiCl₂(g) are estimated by assuming they correspond to the inverted states of NiCl₂(g) (2). The linear configuration is assumed because experimental evidence (3) indicates that other transition metal difluorides, viz. those of Mn, Co, Ni, Cu, and Zn, are linear.

GF_W = 129.2168

(CRYSTAL)

ZIRCONIUM DIFLUORIDE (ZrF₂)Zirconium Difluoride (ZrF₂)GF_W = 129.2168

(Crystal)

 $\Delta H_f^\circ = \text{Unknown}$ $\Delta H_f^\circ_{298.15} = [-230 \pm 15] \text{ kcal/mol}$ $\Delta H_m^\circ = [9 \pm 2] \text{ kcal/mol}$ $\Delta H_s^\circ_{298.15} = [96.6] \text{ kcal/mol}$ $S^\circ_{298.15} = [18 \pm 2] \text{ gibbs/mol}$ $T_m = [1175 \pm 150]^\circ\text{K}$

Heat of Formation

More recent thermal data related to the heat of formation of ZrF₂(c) is unavailable. The adopted ΔH_f° (ZrF₂, c) value is taken from (1) which was estimated by Brewer (2).

Heat Capacity and Entropy

The heat capacities in the temperature range 298-2000°K are estimated by comparison with those of ZrF₄(c) and Zr(c). The S°_{298} is calculated as 17.2 and 17.0 eu based on the assumptions that $S(\text{ZrF}_2) = 1/2[S(\text{ZrF}_4) + S(\text{Zr})]$ and $S(\text{ZrF}_2) = S(\text{ZrF}_2) - S(\text{Zn}) + S(\text{Zr})$. Using the additive entropy constants $S^\circ_{298} = 12.1$ and 4.7 eu for Zr and F suggested by Kubaschewski and Evans (3), we obtain $S^\circ_{298}(\text{ZrF}_2, c) = 12.1 + 2(4.7) = 21.5$ eu. Based on $S^\circ_{298} = 11.5$ and 3.9 eu for Zr⁴⁺ and F⁻ recommended by Kelley (4), the value $S^\circ_{298}(\text{ZrF}_2, c)$ is derived as 19.3 eu. The entropy at 298°K for ZrF₂(c) is tentatively adopted as 18 ± 2 eu.

Melting Data

Both T_m and ΔH_m° are estimated. The derived entropy of melting, 2.55 eu/atom, is the same as that of ZrF₄(c) which was obtained from experimental measurements (5). Therefore these estimated values are tentatively adopted.

Heat of Sublimation

The difference between ΔH_f° for ZrF₂(g) and ZrF₂(c) is $\Delta H_s^\circ_{298}$.

(LIQUID)

ZIRCONIUM DIFLUORIDE (ZrF₂)

GFW = 129.2168

S_{298.15}^o = [24.103] gibbs/mol $\Delta H_f^{\circ}{}_{298.15}$ = [-222.502] kcal/molT_m = [1175 ± 150]*K ΔH_m° = [9 ± 2] kcal/molT_b = [2529]*K ΔH_v° = [169.0] kcal/mol

Heat of Formation

The $\Delta H_{f298}^{\circ}(\ell)$ is obtained from $\Delta H_{f298}^{\circ}(c)$ by adding ΔH_m° and the difference between H_{1175}° - H_{298}° for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated from those of ZrF₄(ℓ), CaF₂(ℓ), Zr(ℓ), and Ca(ℓ), and is assumed to be constant in the temperature range 800-1000°K. A glass transition temperature is assumed at 800°K. The Cp values below 800°K are adopted from the ZrF₂(c) table.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

Both T_m and ΔH_m° are estimated. The derived entropy of melting, 2.55 eu/atom, is the same as that of ZrF₄(c) which was obtained from experimental measurements (1). Therefore these estimated values are tentatively adopted.

Vaporization Data

T_b is the temperature at which the Gibbs energy change of the process ZrF₂(ℓ) = ZrF₂(g) approaches zero. The difference between ΔH_f° for ZrF₂(ℓ) and ZrF₂(g) at T_b is ΔH_v° .

Product of the Moments of Inertia: $I_{AB}^2 C = (1.3968 \times 10^{-114}) \text{ g cm}^6$
 $\sigma = 2$

Heat of Formation

Murad and Hildenbrand (1) studied the gaseous equilibria involving ZrF_4 , ZrF_3 , ZrF_2 , Ca , and CaF , mass-spectrometrically. Ion intensities were measured 3 eV above threshold over the temperature range 1665-1747°K, and the equilibrium constants for the reaction $2 Ca(g) + ZrF_4(g) = 2 CaF(g) + ZrF_2(g)$ were calculated. Using the reported equilibrium constants, the enthalpy changes (ΔH_f°) of this reaction are evaluated by the second and third law methods to be 15.4 and 50.9 kcal/mol, respectively. The drift in third law values is 70.4 ± 17.6 eu. Based on the third law ΔH_f° value and $\Delta H_f^\circ(298) = 42.85 \pm 0.3$, -65.0 ± 2 , and -400.0 ± 0.5 kcal/mol for $Ca(g)$, $CaF(g)$, and $ZrF_4(g)$, respectively, we obtain $\Delta H_f^\circ(298)$ for $ZrF_2(g) = -133.4 \pm 5$ kcal/mol, which is adopted.
Using Gibbs energy functions derived from different molecular constants for the reactants and products, Murad and Hildenbrand (1) derived a third law $\Delta H_f^\circ(298) = 42.6 \pm 5$ and $\Delta H_f^\circ(298)$ for $ZrF_2(g) = -141 \pm 5$ kcal/mol, which are in fair agreement with the adopted values.

Heat Capacity and Entropy

According to the correlations of Charkin and Dyatkina (2), the $ZrF_2(g)$ molecule has an angular configuration. The $F-Zr-F$ angle is estimated as 125° , which is similar to the value reported by Hastie, Hauge, and Margrave (3) for $TiF_2(g)$. The $F-Zr$ bond distance is estimated from that of $ZrF_4(g)$. The vibrational frequencies are calculated based on the method suggested by Herzberg (3). The value ν_1 is calculated from the vibrational frequency (ν) of $ZrF(g)$ by use of the relation $\nu_1 = \nu \sqrt{\frac{M_{Zr}}{M_{Ti}}}$, where Zr and F are gram atomic weights of zirconium and fluorine. ν_3 is derived from ν_1 using the formula $\nu_3 = \nu_1 \sqrt{\frac{2M_{Zr}}{M_{Ti}}}$, where ν_3 is calculated as $0.44 \nu_1$ where the value 0.44 is estimated by comparison with the ratios of ν_2/ν_3 for other related compounds. Ground state quantum weight is taken to be the same as that of $TiF_2(g)$. The three principal moments of inertia are: $I_A = 1.830 \times 10^{-38}$, $I_B = 3.502 \times 10^{-39}$ and $I_C = 2.180 \times 10^{-38} \text{ g cm}^2$. The electronic levels and quantum weights are estimated to be the same as those of $TiF_2(g)$.

IRON TRIFLUORIDE (FeF₃)

(CRYSTAL)

$$\Delta H_f^0 = \text{Unknown}$$

$$\Delta H_f^0 = -249 \pm 3 \text{ kcal. mole}^{-1}$$

$$\Delta H_g^0 = [52.8] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = [23.5 \pm 2] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_g = [1200]^{\circ}\text{K.}$$

Heat of Formation.

The equilibrium pressures for the reaction $2\text{FeF}_3(\text{c}) + \text{H}_2(\text{g}) = 2\text{FeF}_2(\text{c}) + 2\text{HF}(\text{g})$ have been measured at temperatures 623, 723 and 823°K. by K. Jellinek and A. Rudat, Z. anorg. allgem. Chem. 175, 281 (1928). Using the reported data, the enthalpy change of the reaction was evaluated as 37.9 and 31.3 kcal. mole⁻¹ by the third and second law methods, respectively. The corresponding ΔH_f^0 298.15 (FeF₃, c) values are calculated to be -252.4 and -249.2 kcal. mole⁻¹. The equilibrium constants for the reaction $2\text{FeF}_3(\text{c}) + 3\text{H}_2\text{O}(\text{g}) = \text{Fe}_2\text{O}_3(\text{c}) + 6\text{HF}(\text{g})$ were determined by L. Domange, Ann. Chim., 7, 225 (1937). Based on the third law value of ΔH_f^0 298.15, 62.0 kcal. mole⁻¹, the ΔH_f^0 298.15 (FeF₃, c) was calculated as -237.4 kcal. mole⁻¹. The value of ΔH_f^0 298.15 for FeF₃(c) is selected to be -249 ± 3 kcal. mole⁻¹.

Heat Capacity and Entropy.

The heat capacities of FeF₃(c) at temperatures 100-450°K. were determined by H. Bizette, R. Mainard and J. Picard, Comp. rend. 5508 (1965). The results were presented graphically by plotting C_p vs. T. The C_p curve shows a peak at 367°K. An antiferromagnetic transition at about 394°K. was reported by E. O. Mollan, H. R. Child, W. C. Koshler and M. K. Wilkinson, Phys. Rev. 112, 1132 (1958). The heat capacities above 450°K. and 528.15 were estimated by comparison with those for FeCl₃(c) AlCl₃(c) and AlF₃(c).

Sublimation Data.

The phenomenon that FeF₃(c) sublimes without fusion at temperatures near 1000°C has been observed and reported by Poulenc, Ann. Chim. phys. (7), 2, 1 (1894). Based on this data the value of T_m was estimated. The value of heat of sublimation (ΔH_s^0 298.15) was calculated using an estimated entropy of sublimation, $\Delta S_s^0 = 40$ e.u. In order to have $\Delta H_s^0 \approx 0$ for the reaction $\text{FeF}_3(\text{c}) = \text{FeF}_3(\text{g})$ at 1200°K.

 $\sigma^{\circ} = [6]$

Heat of Formation.

The value of $\Delta H^{\circ}_f 298.15$ (FeF₃, g) was calculated from $\Delta H^{\circ}_f 298.15$ and $\Delta H^{\circ}_f 298.15$ for FeF₃(c). The value $\Delta H^{\circ}_f 298.15 = 65.5 \text{ kcal. mole}^{-1}$ was derived from $\Delta H^{\circ}_f 1200$ (see FeF₃(c) table for details).

Heat Capacity and Entropy.

The molecular structure, bond distance and angle were estimated by comparison with those for AlF₃(g). The vibrational frequencies were estimated by comparison with those for AlF₃(g), TlF₃(g) and ZrF₃(g). The three principal moments of inertia are: $I_A = I_B = 1.7081 \times 10^{-38}$ and $I_C = 3.4182 \times 10^{-38} \text{ g. cm.}^2$.

Heat of Formation

The heat of formation (ΔH_f°) is derived based on the adopted value $\Delta H_f^\circ = 79.73 \text{ kcal/mol}$ for the reaction $3\text{LiF}(c) = \text{Li}_3\text{F}_3(g)$, using $\Delta H_f^\circ(\text{LiF}, c) = -147.45 \text{ kcal/mol}$. The ΔH_f° value is calculated to be $73.9 \pm 1 \text{ kcal/mol}$ reported by Büchler and Strauffer (1) and Akishin et al. (2), respectively. Using the adopted ΔH_f° values for monomer, dimer, and trimer, we also evaluate the value $\Delta H_f^\circ = 53.8 \text{ kcal/mol}$ for the reaction $\text{Li}_3\text{F}_3(g) = \text{Li}_2\text{F}_2(g) + \text{LiF}(g)$ which is in agreement with the value $50 < \Delta H_f^\circ < 65 \text{ kcal/mol}$ reported by Porter and Schoonmaker (3). Rothberg et al. (4) have determined the partial pressures of LiF monomer, dimer, and trimer in the temperature range $980 - 1070^\circ\text{K}$, using the molecular-beam velocity-selector method (5). However, the total pressures derived from these data are too low in comparison with the other reported vapor pressures. Thus their data are not adopted for evaluation.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that of the BeO trimer. The Li-F bond distance is taken from that of the Li_2F_2 molecule determined by Akishin and Rambidi (6). Four vibrational frequencies, ν_2 and three ν_1 , are reported by Snelson (7) from analysis of the infrared spectra of LiF using the matrix isolation technique. The reported frequencies are corrected to the average isotopic species. The other four frequencies, ν_2 and three ν_1 , are estimated by comparison with those for the isoelectronic molecule Be_3O_3 . The three principal moments of inertia are $I_A = I_B = 1.83 \times 10^{-38}$ and $I_C = 3.646 \times 10^{-38} \text{ g cm}^2$.

Bond Distance: N-F = 1.371 Å
 Bond Angle: F-N-F = 102.9°
 Product of the Moments of Inertia: $I_A I_B I_C = 8.855 \times 10^{-115} \text{ g}^3 \text{ cm}^6$
 $\sigma = 3$

Heat of Formation

The adopted heat of formation was obtained from a simultaneous adjustment of several interrelated pieces of data relating to the heat of formation of HF (see HF, g table 12-31-68). The data which was considered relating directly to NF₃ was as follows.

A. $8 \text{ NF}_3(\text{g}) + 3 \text{ C}_2\text{H}_4(\text{g}) \rightarrow 6 \text{ CF}_4(\text{g}) + 7 \text{ N}_2(\text{g})$

Walker (1) reported $\Delta H_{298}^\circ = -1308.8 \pm 1.3 \text{ kcal/mol}$.

B. $\text{NF}_3(\text{g}) + 1.5 \text{ H}_2(\text{g}) \rightarrow \text{NH}_3(50 \text{ H}_2\text{O}) + 0.5 \text{ N}_2(\text{g})$

Sinke (2) reported $\Delta H_{298}^\circ = -199.49 \pm 0.22 \text{ kcal/mol}$ for a final state of HF(123 H₂O); the corrected value is $-199.40 \pm 0.22 \text{ kcal/mol}$.

C. $2 \text{ NF}_3(\text{g}) + \text{S}(\text{c, rh}) \rightarrow \text{SF}_6(\text{g}) + \text{N}_2(\text{g})$

Walker (3) reported $\Delta H_{298}^\circ = -228.26 \pm 0.25 \text{ kcal/mol}$.

D. $\text{NF}_3(\text{g}) + 0.5 \text{ N}_2(\text{g}) + 1.5 \text{ F}_2(\text{g})$

Sinke (4) reported $\Delta H_{298}^\circ = 31.44 \pm 0.3 \text{ kcal/mol}$ for the above dissociation from experimental explosion of hydrogen in 10 percent and 100 percent excess NF₃.

E. $\text{NF}_3(\text{g}) + \text{B}(\text{c, } \beta) \rightarrow \text{BF}_3(\text{g}) + 0.5 \text{ N}_2(\text{g})$

Ludwig and Cooper (5) reported $\Delta H_{298}^\circ = -239.46 \pm 1.2 \text{ kcal/mol}$, 5 percent of the boron remained unreacted and was detected by analysis.

Further details of the simultaneous adjustment are given by Syverud (6).

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Schatz and Levin (7) and are in good agreement with those of Pace and Pierce (8), and Wilson and Polo (9). The adopted values are also in agreement with the Raman studies of Kotov and Tatevskii (10). The bond length and angle were from the microwave studies of Sheridan and Gordy (11), whose values are in substantial agreement with the electron diffraction results of Schomaker and Liu (12).

The individual moments of inertia are $I_A = I_B = 7.854 \times 10^{-39} \text{ g cm}^2$ and $I_C = 14.354 \times 10^{-39} \text{ g cm}^2$.

Pierce and Pace (13) have obtained the entropy of the gas at 144.15°K from solid heat capacity measurements and the heats of melting and vaporization. Their reported value of 54.50 eu is in good agreement with our calculated value of 54.56 eu.

Vibrational Frequencies and Degeneracies

ω, cm⁻¹

Heat of Formation

Bougon et al. (1) determined equilibrium constants for the reaction NOF(g) + F₂(g) ⇌ NOF₃(g) as a function of temperature and total pressure. Second and third law analyses of these equilibrium data are given below:Product of the Moments of Inertia: I_AI_BI_C = [4.0703 × 10⁻¹¹⁴] g³ cm⁶

Bond Distance: N-O = [1.151] Å N-F = 1.48 ± 0.1 Å

Bond Angle: ONF = [109° 28'] ONF = [109° 28']

Point Group C_{3v}

Ground State Quantum Weight = 1

GF_W = 87.0013ΔH_f⁰ = -37.0 ± 5.0 kcal/molΔH_f

GF_W = 103.9684

(IDEAL GAS)

PHOSPHORYL FLUORIDE (POF₃) $\Delta H_f^\circ = -293.9 \pm 1.9 \text{ kcal/mol}$ Point Group C_{3v}C_{3v} $\Delta H_f^\circ = -295.6 \pm 1.9 \text{ kcal/mol}$ $S_{298.15}^\circ = 68.10 \pm 0.07 \text{ gibbs/mol}$

Ground State Quantum Weight = 11

Vibrational Frequencies and Degeneracies

$\frac{\omega_e}{\text{cm}^{-1}}$	$\frac{\omega_e}{\text{cm}^{-1}}$
1417.7 (1)	994 (2)
872.8 (1)	483.2 (2)
473.2 (1)	335.6 (2)

Band Distance: P-0 = 1.45 ± 0.03 Å P-F = 1.52 ± 0.02 Å

Band Angle: F-P-F = 102.5° ± 2° F-P-O = 115.8° ± 2°

Product of Moments of Inertia: $I_A I_B I_C = 5.9019 \times 10^{-114} \text{ g cm}^6$

Heat of Formation

Ebel and Bretscher (1) measured the enthalpy change for the following reaction:

 $\text{PF}_3(\text{g}) + 1/2 \text{O}_2(\text{g}) + \text{POF}_3(\text{g})$ They reported a heat of reaction of $-70.6 \pm 1 \text{ kcal/mol}$. Combining this result with the heat of formation of PF_3 , $\Delta H_f^\circ = -224.9 \pm 0.9 \text{ kcal/mol}$ (2), we derive, $\Delta H_f^\circ(\text{POF}_3, \text{g}) = -295.6 \pm 1.9 \text{ kcal/mol}$.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Sellig and Claassen (3) and are in good agreement with the Raman and infrared studies of Gutowsky and Liehr (4). Several microwave studies ($\bar{\nu}$, $\bar{\nu}$, $\bar{\nu}$) of POF_3 have been reported. As pointed out by Williams et al. (2), the rotational constant calculated from their microwave studies leads to a moment of inertia, I_B , which is in disagreement with the moment of inertia calculated from the molecular constants obtained from electron-diffraction studies by Brockway and Beach (5). Since insufficient microwave data were available for an independent determination, Williams et al. (2) sought to find parameters which were consistent with both measurements. Their molecular constants are adopted for this tabulation. Individual moments of inertia are $I_A = I_B = 18.244 \times 10^{-39} \text{ g cm}^2$ and $I_C = 17.731 \times 10^{-39} \text{ g cm}^2$.

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
892 (1)	860 (2)
487 (1)	344 (2)

Bond Distance: P-F = $1.5700 \pm 0.0012 \text{ \AA}$ F...F = $2.3643 \pm 0.0028 \text{ \AA}$ Bond Angle: F-P-F = $97.8 \pm 0.2^\circ$ Product of Moments of Inertia: $2.0621 \times 10^{-114} \text{ g}^3 \text{ cm}^6$ $\sigma = 3$

Heat of Formation

Berthelot (1) measured the heats of hydrolysis of PF₃(g) and PCl₃(l). These results can be combined to give, $\Delta H_f^\circ = 24.5 \text{ kcal/mol}$, for the reactionPF₃(g) + 3KCl·157 H₂O + PCl₃(l) + 3KF·112 H₂O.

Combining this result with the following heat of formation data,

 $\Delta H_f^\circ(\text{PCl}_3, l) = -72.2 \text{ kcal/mol}$ (2) $\Delta H_f^\circ(\text{KCl} \cdot 157 \text{ H}_2\text{O}) = -100.0 \text{ kcal/mol}$ (3) $\Delta H_f^\circ(\text{KF} \cdot 112 \text{ H}_2\text{O}) = -138.5 \text{ kcal/mol}$ (3)we derive, $\Delta H_f^\circ(\text{PF}_3, g) = -212.2 \text{ kcal/mol}$.Duus and Nykytnik (4) reported a heat of reaction of -2.361 kcal/mol (corrected to 25°C) for the following reactionPCl₃(g) + 3/2 CaF₂(c) + PF₃(g) + 3/2 CaCl₂(c).

Combining this result with the following heat of formation data,

 $\Delta H_f^\circ(\text{PCl}_3, g) = -64.4 \text{ kcal/mol}$ (2) $\Delta H_f^\circ(\text{CaF}_2, c) = 293.0 \pm 1.5 \text{ kcal/mol}$ (5) $\Delta H_f^\circ(\text{CaCl}_2, c) = -190.0 \text{ kcal/mol}$ (3)we derive, $\Delta H_f^\circ(\text{PF}_3, g) = -221.9 \text{ kcal/mol}$.Recently, Rudzitis et al. (6) measured the heat of combustion of PF₃ in fluorine in a two-chambered bomb calorimeter at 25°C. They reported a heat of combustion of $-152.0 \pm 0.2 \text{ kcal/mol}$ for the reactionPF₃(g) + F₂(g) + PF₅(g).Combining this result with the heat of formation of PF₅, $\Delta H_f^\circ(\text{PF}_5, g) = -376.9 \pm 0.7 \text{ kcal/mol}$ (7), we derive, $\Delta H_f^\circ(\text{PF}_3, g) = -224.9 \pm 0.9 \text{ kcal/mol}$. This result is adopted for this tabulation.

Heat Capacity and Entropy

The vibrational frequencies are those reported by Wilson and Palo (8). Several different values for the P-F bond length and F-P-F bond angle have been reported in the literature. This problem was recently discussed by Morino et al. (9), who also reported new data obtained from electron-diffraction studies. Their results are adopted for this tabulation. Individual moments of inertia calculated according to their structure are: $I_A = I_B = 10.814 \times 10^{-39} \text{ g cm}^2$ and $I_C = 17.634 \times 10^{-39} \text{ g cm}^2$.

442 (1)	275 (2)	
695 (1)	402 (2)	
Bond Distance: P-S = 1.87 ± 0.03 Å P-F = 1.53 ± 0.02 Å		
Bond Angle: F-P-F = 100.3° ± 2° F-P-S = 117.6° ± 2°		
Product of Moments of Inertia: $I_A I_B I_C = 1.7316 \times 10^{-113} \text{ g}^3 \text{ cm}^6$		

Heat of Formation

The heat of formation of PSF₃ is calculated from the heat of formation of POF₃ and estimated P-O and P-S bond strengths. Mortimer (1) calculated several P-O and P-S bond dissociation energies from heat of reaction data reported in the literature. Some of these data are given below.

ΔH oxidation PF₃ to POF₃ΔH oxidation P(OEt)₃ to PS(OEt)₃ΔH oxidation PPr₃ to PSPr₃

D(P=O) D(P=S) kcal/mole

130.3

81.6

82.6

Mole and McCoubrey (2) reported the following heat of reaction:

PCl₃(g) + S(c) = PSCl₃(g). ΔHr = -5.6 kcal/mol.

Combining this result with heat of vaporization data for PCl₃ (3) and PSCl₃ (4), along with the heat of sublimation of S (5), we derive, D(P-S) = 71 kcal/mol. Averaging this result with the two values given above, we obtain D(P-S) = 78.4 kcal/mol.

We assume that this result represents the enthalpy change for reaction

PSF₃(g) + PF₃(g) + S(g).

Combining this result with similar data for POF₃, namely D(P=O) = 130.3 kcal/mol and ΔHf^o(POF₃, g) = -295.6 ± 1.9 kcal/mol (6), we derive, ΔHf^o(PSF₃, g) = -237 ± 15 kcal/mol, from the relationship

$$\Delta H_{298}^\circ(\text{PSF}_3, g) = \Delta H_{298}^\circ(\text{POF}_3, g) + \Delta H_{298}^\circ(\text{S}, g) - \text{D}(\text{P=O}) + \text{D}(\text{P=S}).$$

Heat Capacity and Entropy

Several recent infrared and Raman studies (7, 8, 9, 10) of PSF₃ have been reported. These data are in good agreement, except for the ν₁ fundamental. Dewaulle and Francoise (11) assigned this fundamental to the 469 cm⁻¹ band observed in their spectra. The recent work indicates that this fundamental should be assigned to the 981 cm⁻¹ band. Average values of the vibrational frequencies reported by (8, 9, 10) are adopted for this tabulation. The molecular structure of this molecule was determined by Williams et al. (12) and Hawkins and Cohen (13) from microwave studies. The individual moments of inertia calculated from the constants given by Williams et al. (12) are I_A = I_B = 3.1527 × 10⁻³⁸ g cm² and I_C = 1.7410 × 10⁻³⁸ g cm².

Bond Distance: Si-F = (1.56) Å

Bond Angle: F-Si-F = (109.47)°

Product of the Moments of Inertia: I_AI_BI_C = 2.5135 × 10⁻¹¹⁴ g³ cm⁶

σ = 3

Heat of Formation

The heat of formation is estimated from the assumption of a 0.5 kcal heat for the reaction:

SiF₄(g) + SiF₂(g) + 2SiF₃(g) ΔH = 0.5 kcal

ΔH°_{f,298}(SiF₃, g) = -263 kcal/mol is derived from ΔH°_{f,298}(SiF₄, g) = -385.98 kcal/mol and ΔH°_{f,298}(SiF₂, g) = -140.5 kcal/mol. The above value is confirmed by the observations of Layne (1), whose total pressure data above the silicon -- magnesium fluoride system agree with those calculated from these tables.

Heat Capacity and Entropy

The bond length is estimated between those of SiF₄ and SiF₂. The vibrational frequencies are from Milligan et al. (2), and the angle is taken to be tetrahedral, since they also reported an angle of approximately 71° between the Si-F bonds and the threefold axis. The spectra of the radical were obtained in inert gas matrices and all the fundamentals were observed. The individual moments of inertia are I_A = I_C = 11.081 × 10⁻³⁹ g cm², I_B = 20.472 × 10⁻³⁹ g cm².

Heat of Formation

Blocher and Hall (1) have reported vapor pressure data for the process $1/2\text{Hg}_2\text{F}_2 + \text{TiF}_3(\text{c}) = \text{TiF}_4(\text{g}) + \text{Hg}(\text{l})$. Second and third law analyses of their data give a second law ΔH°_{298} of 23.7 kcal/mol, a third law ΔH°_{298} of 29.864, and a third law drift of 11.9 ± 1.0 eu. The third law value is combined with the JANAF values for the heat of formation of $\text{Hg}_2\text{F}_2(\text{c})$ and $\text{TiF}_4(\text{g})$ to give a ΔH°_{298} of -343.1 ± 10.0 kcal/mol. The large uncertainty on ΔH°_{298} is assigned because Blocher and Hall were not able to identify $\text{TiF}_3(\text{c})$ as the reaction product in the above process. They reported that the X-ray pattern of the products contained lines corresponding to $\text{Hg}_2\text{F}_2(\text{c})$ plus others that did not correspond to $\text{TiF}_3(\text{c})$.

Heat Capacity and Entropy

The heat capacity of $\text{TiF}_3(\text{c})$ is estimated from the heat capacities of ZrF_4 and TiF_4 . The entropy, S°_{298} , is estimated from CrF_3 and from ionic entropy contributions. Both methods give values which are within ± 0.8 eu of the chosen value of 21 ± 3 eu.

Heat of Sublimation

The heat of sublimation is calculated from the vapor pressure data of Zmbov and Margrave (2). See $\text{TiF}_3(\text{g})$ table for details. The sublimation temperature is taken as the point at which $\Delta G = 0$ for the reaction $\text{TiF}_3(\text{c}) = \text{TiF}_3(\text{g})$.

Product of the Moments of Inertia: I_AI_BI_C = [7.45 × 10⁻¹¹⁴ g³ cm⁶]

Heat of Formation

The heat of formation of TiF₃(g) is calculated from that of TiF₃(c) and the heat of sublimation determined from the mass spectrometric vapor pressure data of Zmbov and Margrave (1). Their data give nine points over the temperature range 759 - 865°K.

Second and third law analyses of their data give a second law ΔH_f₂₉₈ of 61.2 ± 0.4 kcal/mol and a third law ΔH_f₂₉₈ of 59.0 kcal/mol with an entropy drift of -2.7 ± 0.5 units. The third law value is used to calculate ΔH_f₂₉₈.

Heat Capacity and Entropy

The interatomic distance is estimated from those of TiF₄(g), and TiCl₄(g), and TiCl₃(g). The pyramidal bond angle is estimated assuming TiF₃(g) similar to the group V trihalides. The principal moments of inertia are I_A = I_B = 1.68 × 10⁻³⁶ g cm² and I_C = 2.66 × 10⁻³⁸ g cm². The vibrational frequencies are estimated from those of PF₃ and AsF₃. The electronic levels are estimated from the levels of Ti³⁺ (2).

Heat of Formation

The heat of formation at 298°K for ZrF₃(c) was reported as -350 kcal/mol (2) which was estimated by Brewer (2). Based on this ΔHf₂₉₈ value, the crystal lattice energy (U) of ZrF₃(c) is calculated to be 1371 kcal/mol by the Born-Haber cycle method (3). For the evaluation of U from the relation: ΔHf^o(ZrF₃, c) = Σ I₁ + L - 3(E - D/2) - U, the following values (kcal/mol) are used: Σ I₁ (the sum of the successive three ionization potentials of Zr metal) = 1055 (4), L (the enthalpy of sublimation of Zr metal) = 148.3 (5), E (the electron affinity of fluorine) = 79.5 (6), and D (the enthalpy of dissociation of fluorine) = 37.7 (7). The derived value of U(ZrF₃, c) is of the same order of magnitude of the value, U(TiF₃, c) = 1376 kcal/mol, calculated by Cavell and Clark (3) using the same method.

From ΔHf₂₉₈^o(ZrF₃, c) = -350 kcal/mol, the derived ΔGf^o(ZrF₃, c) values indicate that ZrF₃(c) is thermodynamically more stable than the system ZrF₄(c) + Zr(c). For example, in the temperature range 798-1200°K, the Gibbs energy changes for the reaction 3 ZrF₃(c) + Zr(c) = 4 ZrF₄(c) are about -29 ± 1 kcal/mol. However, this product ZrF₃(c) has never been prepared successfully from this reaction in many laboratories (8). In order to make the ΔGf^o(ZrF₃, c) values consistent with the experimental observations, the heat of formation of ZrF₃(c) is arbitrarily adjusted to be 15 kcal/mol less negative, or ΔHf₂₉₈^o(ZrF₃, c) = -335 kcal/mol with uncertainty as high as ±20 kcal/mol. This value is tentatively adopted.

The Gibbs energy changes for the reaction 3 ZrF₃(g) + Zr(c) = 4 ZrF₄(c) are evaluated to be very favorable at temperatures below 900°K, e.g., ΔGr^o = -93.9 and -6.7 kcal/mol at 298 and 900°K, respectively. But according to Larsen and Leddy (9), this reaction does not occur in the temperature range 473-973°K, and pressure range 5-15 atm. One possible explanation is that these heterogeneous reactants may require very high activation energy to initiate the reaction. In other words, this reaction is unfavorable at these temperatures probably due to kinetic rather than thermodynamic reasons.

Heat Capacity and Entropy

The heat capacities of ZrF₃(c) are not available in the literature. They are estimated from the Cp values of ZrF₄(c) by deduction of one F atom Cp contributions which are calculated as 1/4(Cp_{ZrF₄}(c) - Cp_{ZrF₃}(c)). The S_{298.15}^o is taken to be 1/2(S₂₉₈^o(ZrF₄, c) + S₂₉₈^o(ZrF₂, c)) of which the value S₂₉₈^o(ZrF₂, c) is estimated (see ZrF₂(c) table for details).

Heat of Sublimation

The difference between ΔHf₂₉₈^o for ZrF₃(g) and ZrF₃(c) is ΔHs₂₉₈^o. Actually, ZrF₃(c) is thermodynamically unstable, e.g., the Gibbs energy changes for the reaction 4 ZrF₃(c) = 3 ZrF₄(c) + Zr(c) are about -30 kcal/mol in the temperature range 298-1400°K. In other words, ZrF₃(c) decomposes into ZrF₄(c) + Zr(c) before sublimation occurs.

Heat of Formation

Murad and Hildenbrand (1) studied the gaseous equilibria involving ZrF₄, ZrF₃, ZrF₂, Ca and CaF₂. These species were generated at high temperatures in a graphite Knudsen cell containing powdered calcium fluoride and elemental zirconium. Ion intensities were measured 3 eV above threshold over the temperature range 1665-1747°K and the equilibrium constants were calculated for the following isomolecular reaction: $\text{Ca(g)} + \text{ZrF}_4(\text{g}) = \text{CaF(g)} + \text{ZrF}_3(\text{g})$. Based on the reported equilibrium constants, the enthalpy change of this reaction is evaluated by the second and third law methods as -8.0 ± 2.5 and -78.0 ± 2 kcal/mol, respectively. The third law entropy drift is 20 ± 15 eu. Using the third law value and $\Delta H_{f298}^\circ = 42.85 \pm 0.3$, -400.0 ± 0.5 , and -65.0 ± 2 kcal/mol for Ca(g), ZrF₄(g), and CaF(g) we obtain $\Delta H_{f298}^\circ(\text{ZrF}_3, \text{g}) = -264.2 \pm 5$ kcal/mol, which is adopted. Employing slightly different Gibbs energy functions and ΔH_{f298}° values for the products and reactants, Murad and Hildenbrand (1) evaluated the third law enthalpy change of the above reaction as 29.4 ± 5 and $\Delta H_{f298}^\circ(\text{ZrF}_3, \text{g}) = -262 \pm 5$ kcal/mol, which are in reasonable agreement with the values adopted here.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that of TiF₃(g). The Zr-F bond distance is estimated by comparison with those for ZrF₄(g) and ZrF₂(g). The F-Zr-F bond angle is taken to be slightly larger than the F-Ti-F bond angle in the TiF₃(g) molecule. The vibrational frequencies are calculated by the valence force method (2) using force constants transferred from those for the ZrF₂(g) molecule. The three principal moments of inertia are: $I_A = I_B = 1.8280 \times 10^{-38}$ g cm², and $I_C = 2.9593 \times 10^{-38}$ g cm². The electronic levels are estimated to be three times higher than those of TiF₃(g), based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by C. E. Moore (3). The quantum weights are assumed to be the same as those of TiF₃(g).

Bond Distance: Mg-F = [1.77] Å
Bond Angle: F-Mg-F = [135]°
Product of the Moments of Inertia: I_AI_BI_C = [5.571 X 10⁻¹¹³] g.³ cm.⁶
Mg-F⁺-Mg = [90]°
P⁺-Mg-F⁺ = [90]°
σ = 4

Heat of Formation.

The enthalpy change, ΔH_f^o = 30 kcal. mole⁻¹, for the reaction MgF₂(c) + MgF₂(g) = (MgF₂)₂(g) was determined by J. Berkowitz and J. R. Marquart, J. Chem. Phys. 39, 1853 (1962). Hence the heat of formation for (MgF₂)₂(g) was calculated.

Heat Capacity and Entropy.

The molecular structure was assumed to be planar. The two Mg atoms are at the two opposite corners of a square. The other two corners of the square are occupied by two F atoms. The two remaining F atoms are situated outside the square on a straight line joining the two Mg atoms. The bond distance between Mg and F atom was estimated to be the same as that in the MgF₂(g) molecule. Vibrational frequencies were estimated by comparison with those for MgF(g) and (NaF)₂. The vibrational frequencies for (NaF)₂ were calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960). The three principal moments are 9.8896 X 10⁻³⁹, 7.0235 X 10⁻³⁸, and 8.0163 X 10⁻³⁸ g. cm.²

GFW = 187.933

Heat of Formation

Zimov et al. (1) investigated the stabilities of some molybdenum and tungsten oxyfluorides by means of mass spectrometry. These studies led to heats of formation for $\text{MoO}_2\text{F}_2(\text{g})$, $\text{WO}_2\text{F}_2(\text{g})$, and $\text{MoF}_4(\text{g})$ which were used by the authors to develop a correlation among the heats of formation of the oxides, oxyfluorides, and fluorides of Mo and W. ΔH_f° varies almost linearly with the number of oxygen atoms (1) for the series VF_6 , VOF_4 , and VO_2F_2 . Assuming a similar variation for MoF_6 , MoOF_4 , and MoO_2F_2 , we estimate $\Delta H_f^\circ(\text{MoOF}_4, \text{g}) = -320 \text{ kcal/mol}$.

Heat of formation data (2) for $\text{MoF}_6(\text{g})$, $\text{MoOF}_4(\text{g})$, $\text{MoO}_2(\text{g})$, and $\text{MoO}_3(\text{g})$ have been used to derive the following average bond dissociation energies:

$$\bar{D}(\text{Mo-F}) = 107 \text{ kcal/mol}$$

$$\bar{D}(\text{Mo-O}) = 135 \text{ kcal/mol}$$

From these data we derive $\Delta H_f^\circ(\text{MoOF}_4, \text{g}) = -271 \text{ kcal/mol}$.

The heat of formation for MoOF_4 is tentatively selected as $300 \pm 30 \text{ kcal/mol}$.

Heat Capacity and Entropy

Blanchard (3) suggested that $\text{MoOF}_4(\text{g})$ possessed C_{4v} symmetry by reason of the similarity of its infrared spectra with that of $\text{XeOF}_4(\text{g})$. X-ray diffraction studies of crystalline MoOF_4 by Edwards et al. (4, 5) support this view. The structure of the molecule is assumed to be square-pyramidal. The bond lengths are from the crystallographic studies of MoOF_4 by Edwards et al. (4, 5). Individual moments of inertia are $I_A = I_B = 27.437 \times 10^{-39}$, $I_C = 41.801 \times 10^{-39} \text{ g cm}^2$.

Blanchard (3) reported the following vibrational frequencies and assignments:

$$\nu_1 = 1045, \nu_2 = 720, \nu_3 = 680, \text{ and } \nu_6 = 530 \text{ cm}^{-1}$$

Similar frequencies have been reported by Edwards et al. (4) from their study of the infrared spectra of gaseous MoOF_4 .

The rest of the frequencies and assignments are estimated by comparison with data for $\text{XeOF}_4(\text{g})$.

Heat of Formation

O. T. Armstrong, S. Marantz, and C. F. Coyle, National Bureau of Standards Report No. 5584, October, 1959, studied the reaction

From this reaction, they calculate the heat of formation of N₂F₄ to be -2.0 ± 2.5 kcal. mole⁻¹. The recalculated heat of formation of NH₄F(s) (see NF₂ table) differs from the value quoted in Circular 500 by 0.06 kcal. mole⁻¹. This correction would make the heat of formation of tetrafluorohydrazine more negative by 0.24 kcal. mole⁻¹. In view of the large uncertainty in the heat of formation, however, this correction was not applied.

Heat Capacity and Entropy

The fundamental frequencies were taken from the vapor phase infrared work of J. R. Durig and R. C. Lord, Spectrochim. Acta 19, 1877 (1963). The principal moments of inertia were calculated from the rotational constants reported by D. R. Lide, Jr. and D. E. Mann, J. Chem. Phys. 31, 1129 (1959). Lide and Mann calculated the bond angles for assumed values of the NN and NF distances.

The principal moments of inertia are: I_A = 1.5051 X 10⁻³⁸ gm. cm.², I_B = 2.6315 X 10⁻³⁹ gm. cm.², I_C = 2.9836 X 10⁻³⁸ gm. cm.².

continued from the table nitrogen difluoride (NF₂) (ideal gas).

Heat Capacity and Entropy

M. D. Harmony, R. J. Myers, L. J. Schoen, D. R. Lide, Jr., and D. E. Mann, J. Chem. Phys. 35, 1129 (1961), investigated the infrared spectrum of NF₂. They were able to assign the band center at 1074 cm.⁻¹ to the symmetric stretching mode ω₁. The absorption in the 930-940 cm.⁻¹ region was assigned to ω₃.

M. D. Harmony and R. J. Myers, J. Chem. Phys. 37, 636 (1962), performed matrix isolation experiments on NF₂. They arrived at the assignment ω₁ = 1070 cm.⁻¹, ω₂ = 573 cm.⁻¹, and ω₃ = 931 cm.⁻¹. The stretching frequencies for similar molecules in an N₂ matrix are about 5 cm.⁻¹ below the gas phase values. A comparison of the gas phase and matrix values of ω₁ show excellent agreement.

F. A. Johnson and C. B. Colburn, Inorg. Chem. 1, 431 (1962), report infrared studies on NF₂ but they draw no definite conclusions.

The gas phase value for ω₁ and the matrix values for ω₂ and ω₃ were taken to represent the fundamental vibrational frequencies of NF₂.

Harmony, Myers, Schoen, Lide, and Mann estimated the N-F distance as 1.37 Å and used this with their data to calculate an F-N-F angle of 104.2°. Using these data the moments of inertia are: I_A = 7.3728 X 10⁻³⁹ gm. cm.², I_B = 1.2035 X 10⁻³⁹ gm. cm.², I_C = 8.5763 X 10⁻³⁹ gm. cm.².

TUNGSTEN OXYTETRAFLUORIDE (WOF₄) (CRYSTAL)

OPW = 275.843 F₄OW

ΔH_f^o = Unknown

ΔH_f^o_{298.15} = [-355.37 ± 6] kcal/mol

ΔH_m^o = 1.219 ± 2 kcal/mol

S^o_{298.15} = [42.0 ± 4] gibbs/mol

T_m = 379°K

Heat of Formation.

The heat of formation, ΔH_f^o₂₉₈(WOF₄, c) = -355.37 kcal/mol, is calculated from that of the gas less the heat of sublimation, ΔH_{sub}^o₂₉₈ = 16.97 kcal/mol. The latter is calculated by the third law method from the vapor pressure equation determined by G. H. Cady and O. B. Hargreaves, J. Chem. Soc., 1563 (1961). The second law ΔH_f^o₂₉₈ is 17.01 kcal/mol.

Heat Capacity and Entropy.

The heat capacities are estimated from those of WOCl₄(c), WO₃(c), WO₂(c), WOCl₂(c) and WF₆(c,l).

The entropy, S₂₉₈^o = 42.0 eu, is calculated from ΔS₃₄₈^o = 37.0 eu for WOF₄(c) → WOF₄(g), obtained from the second law analysis of the vapor pressure equation given by Cady and Hargreaves, loc. cit.

It is surprising that this entropy is larger than the corresponding value for WOCl₄(c) (JANAF WOF₄(c) table dated Mar. 31, 1967). In both cases the entropies of the condensed phases are derived from the gas phase values using second law analysis of sublimation and vaporization data. The resulting entropy of melting for WOF₄, 3.2 eu, is much smaller than the value 22.4 eu for WOCl₄. This extreme difference may be a reflection of the uncertainty inherent in derivation of ΔS_m^o as the difference between the values for sublimation and vaporization. If the values of ΔS_m^o are correct, they suggest the possibility of an undiagnosed solid state transition for WOF₄ similar to that observed for WF₆.

Melting Data.

T_m is calculated as the temperature at which the Gibbs energy of reaction WOF₄(c) → WOF₄(l) approaches zero. The difference between the heats of formation for crystal and liquid at the melting point is ΔH_m^o.

O. Ruff, P. Elander, and W. Heller, Z. Anorg. Chem. 52, 256 (1907), reported the melting point as 393°K. Cady and Hargreaves, loc. cit., derived the melting point as 378°K, and the heat of fusion as 2.26 kcal/mol from vapor pressure equations for crystal and liquid. This second law value of ΔH_m^o, when corrected for ΔC_p of vaporization and sublimation, is in good agreement with the value adopted in the tabulation.

TUNGSTEN OXYTETRAFLUORIDE (WOF₄)

(LIQUID)

OFW = 275.843

$\Delta H_{f, 298.15}^{\circ} = [-354.955] \text{ kcal/mol}$
 $\Delta H_m^{\circ} = 1.219 \pm 2 \text{ kcal/mol}$
 $\Delta H_v^{\circ} = 13.4 \text{ kcal/mol}$

$S_{298.15}^{\circ} = [42.8 \pm 4] \text{ gibbs/mol}$
 $T_m = 379^{\circ}\text{K}$
 $T_b = 460^{\circ}\text{K}$

Heat of Formation.

The heat of formation, $\Delta H_{f, 298}^{\circ}(\text{WOF}_4, l) = -354.955 \text{ kcal/mol}$, is calculated from that of the gas less the heat of vaporization, $\Delta H_{v, 298}^{\circ} = 16.555 \text{ kcal/mol}$. The latter is calculated by the third law method from the vapor pressure equation determined by O. H. Cady and O. B. Hargreaves, J. Chem. Soc., 1563 (1961). The second law $\Delta H_{v, 298}^{\circ}$ is 16.60 kcal/mol.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom as suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1959.

The entropy, $S_{298}^{\circ} = 42.8 \text{ eu}$, is calculated from $\Delta S_{415}^{\circ} = 31.2 \text{ eu}$ for $\text{WOF}_2(l) \rightarrow \text{WOF}_2(g)$, obtained from the second law analysis of the vapor pressure equation given by Cady and Hargreaves, loc. cit.

Melting Data.

See WOF₄(c) table (Mar. 31, 1967).

Vaporization Data.

T_b is calculated as the temperature at which the Gibbs energy of reaction $\text{WOF}_4(l) \rightarrow \text{WOF}_4(g)$ approaches zero. The difference between the heats of formation for liquid and gas at the boiling point is ΔH_v° .

O. Ruff, P. Elsner and W. Heller, Z. Anorg. Chem. 52, 256 (1907), reported the boiling point as 459°K. Cady and Hargreaves, loc. cit., derived the boiling point as 459°K, and the heat of vaporization as 14.23 kcal/mol from the vapor pressure equation for the liquid. This second law value of ΔH_v° , when corrected for ΔC_p of vaporization, is in good agreement with the value adopted in the tabulation.

TUNGSTEN OXYTETRAFLUORIDE (WOF₄) (IDEAL GAS)

Point Group [C_{2v}]
S_{298.15} = [80.4] gibbs/mol
Ground State Quantum Weight = 1

ΔH_{f,0}⁰ = -336.4 ± 6 kcal/mol
ΔH_{f,298.15}⁰ = -338.4 ± 6 kcal/mol

Q_{PW} = 275.843

Bond Distance: W-F = [1.85] Å W-O = [1.81] Å
Bond Angle: F-W-O = F-W-F = [120°]
F-W-F = F-W-O = [90°]
F-W-F = [180°]
*Equatorial **Axial
Product of the Moments of Inertia: I_AI_BI_C = [3.868] × 10⁻¹¹³ g³ cm⁶
σ = [2]

Heat of Formation.

The heat of formation, ΔH_{f,298}⁰(WOF₄, g) = -338.4 kcal/mol, is the value determined mass spectrometrically by K. P. Zmbov and J. L. Margrave, Rice Univ., private communication, Mar. 1967, from equilibrium studies of

Heat Capacity and Entropy.

The molecular configuration is assumed to be a trigonal bipyramid similar to that of SOF₄(g), reported by P. L. Oggins, H. L. Roberts and L. A. Woodward.¹ The bond distances W-O and W-F are estimated to be the same as those in WO₃(g) and WF₆(g), respectively. The three principal moments of inertia are I_A = 3.509 × 10⁻³⁸, I_B = 3.698 × 10⁻³⁸ and I_C = 2.981 × 10⁻³⁸ g cm².

All vibrational frequencies are estimated by comparison with those observed in the infrared and Raman spectra for SOF₄(g),¹ MoOCl₄(g),² WO₂Cl₂(g),³ CrO₂Cl₂(g),^{4,5} WO₃(g),⁶ and WF₆(g).⁶ These frequencies are not in point group order.

Heat of Formation

Vaughn and Muettterties (1) reported calorimetric data for the hydrogenation of SF₄. Their experiments produced HF in amounts ranging from 5.8 to 7.5g. Roughly 1.3g should have been present as saturated, real vapor in the bomb volume of 360 ml at the final temperature of the experiment. Although the authors made allowance for this mixture of HF(l) and HF(real vapor), their values appear to be quite unrealistic. More reliable corrections are readily obtained from the recent report by Vanderzee (2) of PVT and calorimetric data for HF liquid and real vapor.We choose to reduce the data to a standard state of HF(l), starting from the authors' values of the calorimeter heat capacity and the observed temperature rise. Calculated values for the heat evolved are corrected by a) an increase of $\sim$ 120 cal for conversion of real vapor to liquid, b) a decrease of 113 to 175 cal for oxidation of H₂S(g) to S(c) in the last three experiments, and c) an increase of 22 to 75 cal for adjustment of the reaction to 25°C from the final temperature of the experiment. At 298.15 K we obtainSF₄(g) + 2H₂(g) + 4HF(l) + S(c), $\Delta H^\circ = -102.9 \pm 4$ kcal/mol,

where the uncertainty is increased by 1.5 kcal/mol for other possible corrections which are neglected due to insufficient information.

The adopted ΔH_f° , -185.6 $\pm$ 6 kcal/mol, is derived from ΔH_f° using $\Delta H_f^\circ = -72.38 \pm [0.5]$ kcal/mol (2, 3) for HF(l). Smith (4) quoted a value of $\Delta H_f^\circ = -176$ kcal/mol for SF₄ as determined by Nicholls (5) from hydrolysis studies. We do not have details of the hydrolysis studies, but the result presumably should be adjusted for changes in ΔH_f° of aqueous HF.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Levin and Berner (6) and are in good agreement with the frequencies reported by Dodd et al. (2) except for the 353 and 171 cm⁻¹ bands. The structural data are from the microwave studies of Tolles and Gwinn (8) and are in good agreement within experimental error with electron-diffraction data reported by Kimura and Bauer (9) and Dising and Sutton (10). Individual moments of inertia calculated from the rotational constants reported by Tolles and Gwinn (8) are I_A = 1.2552 $\times$ 10⁻³⁸ g cm², I_B = 2.0540 $\times$ 10⁻³⁸ g cm², and I_C = 2.6069 $\times$ 10⁻³⁸ g cm².

Heat of Formation.

The heat of formation of SiF₄(g) was measured by direct combination of the elements in a bomb calorimeter by S. S. Wise, J. L. Margrave, H. M. Feder and W. N. Hubbard, *J. Phys. Chem.* **67**, 815 (1963). ΔH_f^o 298.15 was found to be $-385.98 \pm 0.19 \text{ kcal. mole}^{-1}$. Heats of the reaction between SiF₄(g) and Ne(g), 1% HF solution, 0.4% HF solution, a solution of NaF saturated with Ne₂SiF₆, and water have been measured by A. P. Vorob'ev, V. P. Kolesov, and S. M. Skuratov, *Zh. Neorg. Khim.* **5**, 1402 (1960). The value of ΔH_f^o 298.15 for SiF₄(g) was reported to be $-372.4 \pm 0.4 \text{ kcal. mole}^{-1}$ which was not used.

Heat Capacity and Entropy.

The vibrational frequencies used were reported by E. A. Jones, J. S. Kirby-Smith, P. J. H. Woltz, and A. H. Nielsen, *J. Chem. Phys.* **19**, 242 (1951). The values of vibrational frequencies were given as 800(1), 285(2), 1000(3), and 431(3) cm.⁻¹ for SiF₄(g) by D. M. Yost, E. M. Leasette, and S. T. Cross, *J. Chem. Phys.* **4**, 325 (1936). The molecular data were obtained from L. Pauling and L. O. Brockway, *J. Am. Chem. Soc.* **57**, 2684 (1935). The three principal moments of inertia are: $I_A = I_B = I_C = 1.99437 \times 10^{-38} \text{ g. cm.}^2$

TITANIUM TETRAFLUORIDE (TiF₄)

(CRYSTAL)

GFW = 123.8936

ΔHf°₀ = -393.67 ± 0.9 kcal/mol

ΔHf°_{298.15} = -394.2 ± 0.9 kcal/mol

ΔHs°_{298.15} = 21.37 ± 0.1 kcal/mol

S°_{298.15} = 32.02 gibbs/mol

Ts = 558.6°K

Heat of Formation

The heat of formation (ΔHf°_{298.15}) of TiF₄(c) was measured using a fluorine bomb calorimeter by Greenberg et al. (1). Gross et al. (2) reported a value of -393.4 kcal/mol for ΔHf°₂₉₈. The latter measurements were not corrected for impurities in the titanium sample, thus the value reported by Greenberg et al. is adopted.

Heat Capacity and Entropy

The heat capacity of TiF₄(c) has been measured over the temperature range 6° to 304°K by Euler and Westrum (3). They obtained the value of S°₂₉₈ based on S°₁₀ = 0.11 eu. Heat capacities above 300°K are estimated from those of ZrF₄(c) (4).

Heat of Sublimation

The sublimation point is calculated as the temperature at which ΔGr° = 0 for TiF₄(c) = TiF₄(g). The heat of sublimation is obtained from the data of Hall et al. (5).

Heat of Formation

The heat of formation of TiF₄(g) is calculated from that of the crystal and the heat of sublimation, ΔH_{sub}²⁹⁸, obtained from vapor pressure measurements. E. H. Hall, J. M. Blocher, Jr., and I. E. Campbell, J. Electrochem. Soc. 105, 275 (1958), have reported extensive vapor pressure data for the reaction TiF₄(c) = TiF₄(g). Second and third law analyses of their data yielded the following results.

*Calculation based on third law ΔH_f²⁹⁸.

**Four points rejected due to failure of a statistical test.

***Eight points rejected due to failure of a statistical test.

Heat Capacity and Entropy

The interatomic distance is obtained from a correlation of the measured values for TiCl₄(g), TiBr₄(g), TiCl₃⁻², and TiF₆⁻². The principal moments of inertia are I_A = I_B = I_C = 2.724 × 10⁻³⁸ g cm².

The vibrational frequencies are estimated by a valence force field treatment of estimated force constants. The force constants are estimated from a correlation with the constants of CF₄, SiF₄, COCl₂, CBr₄, SiCl₄, TiCl₄ and TiBr₄. The resulting frequencies are adjusted so that calculations of ΔH_f²⁹⁸ by both second and third law methods are in agreement.

ΔH_F⁰ = 56.80 kcal/mol

Heat of Formation

The heat of formation of zirconium tetrafluoride was measured by direct combination of the elements in a bomb calorimeter by Greenberg, Settle, Feder, and Hubbard (1). The reported value ΔH_F⁰(ZrF₄, c) = -456.80 ± 0.25 kcal/mol is adopted.

Heat Capacity and Entropy

The low temperature heat capacities in the temperature range 5 to 307°K were determined by adiabatic calorimetry by Westrum (2). Using these low temperature Cp data the value of S₂₉₈ is derived as 25.024 ± 0.05 eu, based on S₁₀ = 0.0074 eu.

McDonald, Sinke, and Stull (3) measured the high temperature enthalpies of ZrF₄(c) at temperatures 283.9 - 1275.8°K in a copper block drop calorimeter. Smith, Miller, and Taylor (4) used a Bunsen ice calorimeter for the heat-content measurements in the temperature range 273 - 1150°K. These two sets of enthalpy data are not in good agreement. It is possible that the discrepancies are due to the difference in crystal structure of the samples used (see "Transition Data" for more information). In order to join smoothly with the low temperature heat capacities at 298°K, the high temperature heat capacities derived from the enthalpy data of McDonald, Sinke, and Stull (3) are adopted. The Cp values above 1200°K are obtained by smooth extrapolation.

Transition Data

Zirconium tetrafluoride has three crystal structures (α, β and γ) and one amorphous form (δ). From a differential thermal analysis of (NH₄)₃ZrF₇ sample, Chretien and Gaudreau (5) found that ZrF₄(c) has an α and β form with a transition temperature above 678°K. They also determined the densities of α(tetragonal) and β(monoclinic) as 4.25 ± 0.05 and 4.61 ± 0.03 gm/cc, and a transition temperature as Tt(α + β) = 723°K (7). It was observed that the α phase is unstable at all temperatures above 298°K. In reference (5), Gaudreau mentioned the methods of preparation of the four varieties of ZrF₄ and indicated that α-, γ-, and amorphous ZrF₄ transform irreversibly to β-ZrF₄ at 773 - 773°K.

The ZrF₄ sample employed by McDonald, Sinke, and Stull (3) for enthalpy measurement was prepared by dissolving hafnium-free zirconium metal in 48% aqueous HF, and the resulting solution was evaporated to dryness. The crystalline product was heated slowly to 773°K in a platinum boat in a slow current of anhydrous HF. X-ray diffraction showed only crystalline ZrF₄. Wet analysis indicated 54.61 Zr (theory 54.55) and 44.91 F (theory 45.45). Due to the above facts we are uncertain whether the sample prepared is a mixture of α and β forms or a pure ZrF₄(β). Smith, Miller, and Taylor (4) obtained their ZrF₄ sample from the Oak Ridge National Laboratories, Oak Ridge, Tenn. Since the method of preparation of the compound is unavailable from the report, we do not know what kind of sample they used for measurement.

Because of the above complicated situation, we emphasize that this ZrF₄(c) table is not strictly a α, β-combined phase table. However, the differences in the calculated functions are probably not significant.

Melting Data

Tm and ΔH_m⁰ are taken from McDonald, Sinke, and Stull (3). The values were obtained under conditions greater than one atmosphere.

Sublimation Data

The sublimation temperature (Ts) is calculated as the temperature at which the Gibbs energy change of the process ZrF₄(c) = ZrF₄(g) approaches zero. The difference between ΔH_F⁰(g) and ZrF₄(c) at 1179 and 298°K is ΔH_s⁰ and ΔH_F⁰, respectively.

Since the sublimation temperature is lower than the melting point, the ZrF₄ sublimates before it melts.

Heat of Formation

The vapor pressures of ZrF₄(c) in the temperature range 617-1150°K were determined by many investigators using various methods. Based on the reported vapor pressure data, the corresponding heats of sublimation are evaluated by the second and third law methods. Using the third law ΔH_{298}° and $\Delta H_F^\circ(\text{ZrF}_4, \text{c}) = -456.8$ kcal/mol, the heats of formation at 298°K for ZrF₄(g) are evaluated. The results are presented in the table below. The values of $\Delta H_F^\circ(\text{ZrF}_4, \text{g})$ listed in the last column of this table are in excellent agreement which indicate that the estimated missing vibrational frequencies ν_1 and ν_2 are reasonable. The heat of formation at 298°K for ZrF₄(g) is adopted as -400.0 kcal/mol.

Heat Capacity and Entropy

The molecular structure of ZrF₄(g) has been studied by electron diffraction by Spiridonov (11). The configuration was found to be a regular tetrahedron with interatomic distance Zr-F = 1.94 ± 0.02 Å and F-Zr-F bond angle = 109.47° which are adopted. Employing the estimated interaction coefficients and interatomic distance Zr-F = 1.85 Å, Godnev, Aleksandrovskaia, and Rigina (12) calculated three vibrational frequencies for ZrF₄(g) as $\nu_1 = 600$, $\nu_2 = 150$, $\nu_3 = 180$ and $\nu_4 = 230 \text{ cm}^{-1}$. Buchler, Berkowitz, and Dugre (13) observed the infrared spectra of some group IV halides and assigned $\nu_3 = 668$ and $\nu_4 = 190 \pm 20 \text{ cm}^{-1}$ for ZrF₄(g). The frequency ν_3 has also been reported as 670 cm^{-1} (14). The values of ν_3 and ν_4 adopted here are those reported by Buchler, Berkowitz, and Dugre (13). The adopted ν_1 is obtained by correlating the corresponding frequencies of the tetrafluorides of C, Pb, Si, Ti and Ge with their respective interatomic distances. ν_2 is calculated from ν_1 , ν_3 and ν_4 using the relationship $(12) \nu_1 \nu_2 = \sqrt{2(1-\frac{1}{4})}$, where F and Zr are gram atomic weights of fluorine and zirconium, respectively. The three principal moments of inertia are $I_A = I_B = I_C = 3.166 \times 10^{-38} \text{ g cm}^2$.

Heat of Formation

The adopted value is derived from calorimetric data of Settle et al. (2) for the combustion of iodine in fluorine. Although the combustions gave various mixtures of IF₃ and IF₅, the proportions ranged up to almost pure pentafluoride. Reduction of the data gave ΔHf° = -210.60 ± 0.32 kcal/mol for IF₅(g) at 298.15 K. The result is essentially independent of the heptafluoride. Comparison values of -206.9 ± [21] and -208.6 ± [21.7] kcal/mol may be obtained from calorimetric data of Woolf (2) for hydrolysis in water and in aqueous KOH. Uncertainties for these values include large contributions due to auxiliary data (3). In particular, we estimate lower limits of ±0.8 kcal/mol for ΔHf° of HIO₃(1250 H₂O) and KIO₃(1250 H₂O) by comparison with recent data (4).

ΔHf° for the ideal gas is derived from that of the liquid by use of ΔHv° = 9.96 kcal/mol at 298.15 K. ΔHv° was derived by Osborne et al. (5) from measurements of vapor pressure and the second virial coefficient.

Heat Capacity and Entropy

There is no published structural determination for gaseous IF₅, but spectral data are consistent with C_{4v} symmetry and a configuration which is approximately a square pyramid. It is uncertain whether the iodine is located above, in, or below the base of the pyramid and whether or not the axial and equatorial I-F distances are equal. We adopt the structure used by Begun et al. (2) in correlation of infrared and Raman spectra of BrF₅, IF₅, ClF₅, and XeOF₄ by normal coordinate analysis. In this structure the axial bond length is shorter than the equatorial length and the values are close to those observed experimentally for IF₇. The iodine is presumed to be in the base of the pyramid. Simplified Hückel-molecular-orbital calculations (6) predict that C_{4v} is the most stable symmetry, that the axial bond is shorter, and that the equatorial fluorines are distorted toward the axial fluorine. It is not clear to what extent these predictions depend on the simplified HMO model used in the calculations. Begun et al. (2) note that the normal coordinate calculations are insensitive to changes in the bond angles. Principal moments are $I_A = I_B = 10.66 \times 10^{-39}$ and $I_C = 43.65 \times 10^{-39} \text{ g cm}^2$.

Vibrational frequencies are based on the assignments of Begun et al. (2) as modified by the vapor-phase Raman spectra observed by Salig (8). Location of the band center of ν₃ (>200 cm⁻¹) is difficult, so we substitute the liquid value of 190 cm⁻¹. The Raman-active fundamental ν₃ is not observed for IF₅, or any of the similar molecules, so its value is taken from the calculations (2).

Osborne et al. (5) used calorimetric data at low temperatures to derive S° = 57.86 ± 0.06 gibbs/mol for the liquid at 330 K. Combining this with ΔS° based on their vapor pressure equation, the authors obtained S° = 83.06 ± 0.70 gibbs/mol for the ideal gas at 330 K. The corresponding value from this table (82.50) is lower by 0.56 gibbs/mol. Part of this difference arises from uncertainties in ν₃, ν₉, and the product of the moments of inertia. We estimate this uncertainty at about 0.5 gibbs/mol. Another source of minor uncertainty is the neglect of anharmonicity in the calculations.

Bond Distance: (P-F)_{eq} = 1.534 ± 0.004 Å (P-F)_{ax} = 1.577 ± 0.005 Å

Bond Angle: F_{eq}-P-F_{eq} = 120° ± 0.4° F_{eq}-P-F_{ax} = 74.3° ± 0.4°

Product of Moments of Inertia: I_AI_BI_C = 1.614 × 10⁻¹¹³ g³ cm⁶

Heat of Formation

Gross, Hayman, and Stuart (1) measured the heat of combustion of α-white phosphorus in fluorine at 25°C. They reported a heat of formation of -381.4 ± 0.8 kcal/mol (based on α-white phosphorus standard state) calculated from their combustion studies. Similar combustion studies were performed by O'Hare and Hubbard (2). They reported a heat of formation of -380.8 ± 0.3 kcal/mol (α-white phosphorus standard state), which is in excellent agreement with the work of Gross et al. (1). An average value of -381.1 ± 0.5 kcal/mol is adopted for this tabulation. Converting to the P(red, V) standard state with a ΔH trans = 4.2 ± 0.2 kcal/mol (3), we derive, ΔH_f²⁹⁸(PF₅, g) = -376.9 ± 0.7 kcal/mol.

Heat Capacity and Entropy

The molecular structure and bond lengths given above for PF₅ were recently determined by Hansen and Bartell (4) from electron-diffraction studies. These results indicate that PF₅ has a trigonal bipyramidal structure with nonequivalent axial and equatorial bonds. Wyatt et al. (5) determined rotational constants for PF₅ from a study of the infrared vibration-rotation band contour of the ν₄ (575 cm⁻¹) fundamental. Their analysis led to the following P-F bond lengths which are in excellent agreement with the electron-diffraction results: r_{ax} = 1.534 ± 0.024 Å and r_{eq} = 1.581 ± 0.025 Å. Individual moments of inertia, calculated from the rotational constants given by Wyatt et al. (5) and adopted for this table, are I_A = 2.230 × 10⁻³⁸ g cm² and I_B = I_C = 2.690 × 10⁻³⁸ g cm². The electron diffraction data lead to a product of moments of inertia of 1.604 × 10⁻¹¹³ g³ cm⁶.

Several recent infrared and Raman studies (6, 7, and 8) have been reported for PF₅. These data are in good agreement except for the ν₇ fundamental. Griffiths et al. (6) originally assigned this fundamental to the 126 cm⁻¹ band observed in their infrared spectra. Hoskins (7) later attributed this band to one of the pure rotational lines of hydrogen fluoride, which he felt was present in the sample as an impurity. Further work by Griffiths (10) on the pressure dependence of the infrared spectra of PF₅ indicated that the missing fundamental should be assigned to the weak band at 301 cm⁻¹. Deiters and Holmes (11) recently showed that this band is not a fundamental of PF₅ but a difference band (ν₃-ν₂). Very recently, Levin (8) investigated the Raman spectra of solid phosphorus pentafluoride and assigned the ν₇ fundamental to the 179 cm⁻¹ band. Also, Beattie et al. (12) investigated the Raman spectra of PF₅ in the gas phase at 25°C and 125°C and assigned the ν₇ fundamental to 175 cm⁻¹ band which is in excellent agreement with Levin's assignment (8). The fundamental vibrational frequencies of Holmes and Lord (7) are adopted along with Levin's assignment (8) of the ν₇ fundamental (179 cm⁻¹).

MOLYBDENUM HEXAFLUORIDE (MoF₆)

(LIQUID)

GFW = 209.930

S°_{298.15} = 62.07 ± 0.06 gibbs/molΔH_f^o_{298.15} = -379.080 ± 0.3 kcal/molT_m = 290.76°KΔH_m^o = 1.034 ± 0.001 kcal/molT_b = 307.04°K (l + real gas, P = 1 atm, f = 0.966 atm)ΔH_v^o = 6.512 ± 0.04 kcal/molT_b = 308.0°K (l + ideal gas, P = f = 1 atm)ΔH_v^o = 6.562 kcal/mol

Heat of Formation

The adopted heat of formation, ΔH_f^o(MoF₆, l) = -379.080 ± 0.3 kcal/mol, is calculated from the heat of formation of the gas, ΔH_f^o(MoF₆, g) = -372.4 ± 0.2 kcal/mol (1), and the heat of vaporization, ΔH_v^o = 6.680 ± 0.03 kcal/mol at 298.15°K. The value for the heat of vaporization is obtained from a third law analysis of the vapor pressure data reported by Osborne et al. (2). Myers and Brady (3) determined calorimetrically ΔH_r = -154.7 kcal/mol for the hydrolysis reaction:

Heats of formation of Na₂MoO₄ and NaF in the final solution were determined from the following two auxiliary heat of reaction measurements:

ΔH_r = -17.6 kcal/mol ΔH_r = +0.09 Kcal/mol

Combining these results with the following heat of formation data:

we derive ΔH_f(Na₂MoO₄, in soln.) = -351.6 kcal/mol and ΔH_f(NaF, in soln.) = -137.4 kcal/mol. These data, when combined with the results for the hydrolysis of MoF₆, lead to ΔH_f^o(MoF₆, l) = -379.6 kcal/mol. This result is not in agreement with the adopted value.

Heat Capacity and Entropy

The heat capacity measurements for liquid MoF₆ by Osborne et al. (2) are adopted. Outside the observed range Cp was extrapolated linearly with temperature. S°_{298.15} is evaluated from the thermal data of Osborne et al. (2) and the third law of thermodynamics. They reported heat capacity data in the range 5°-350°K with S°₀K = 0.024 gibbs/mol.

Melting Data

Melting point and heat of melting data for MoF₆ have been reported by several investigators. These results are summarized below.

Investigator	Method	Melting Point, °K	ΔH _m ^o , kcal/mol
Osborne et al. (2)	Calorimetric	290.76 ± 0.02	1.034 ± 0.001
Brady et al. (2)	Calorimetric	290.7	1.059 ± 0.010
Cady and Hargreaves (8)	Vapor Pressure	290.55	1.00 ± 0.03*
Ruff and Ascher (9)	Vapor Pressure	290.65	1.31 ± 0.2*

* This value is the difference between the 2nd law heat of sublimation corrected for ΔCp of the process and the adopted heat of vaporization calculated at 290.76°K with (H_{290.76}H_{298.15}) for the vapor and liquid.

The value ΔH_m^o_{290.76} = 1.034 ± 0.001 kcal/mol from Osborne et al. (2) is adopted.

Vaporization Data

Second and third law analyses of various sets of vapor pressure data (2, 8, 9) are summarized below. Corrections for nonideality of the vapor have been calculated from the second virial coefficient equation reported by Osborne et al. (2).

Investigator	Temp. Range, °K	No. of Points	Boiling Point, °K	ΔH _v ^o ₂₉₈ , kcal/mol
Osborne et al. (2)	291.15 - 320.15	21	307.04	6.690
Cady and Hargreaves (8)	290.55 - 307.15	Equation	307.15	6.74
Ruff and Ascher (9)	290.65 - 294.85	4	308.15	5.99
* with ΔCp = -11.77 gibbs/mol				6.68

The value ΔH_v^o₂₉₈ = 6.680 ± 0.03 (ΔH_v^o_{307.04} = 6.512 ± 0.04) kcal/mol, determined from the vapor pressure data of Osborne et al. (2), is adopted in the tabulation. The temperature at which ΔG_v^o = 0 is 308.0°K and the corresponding ΔH_v^o = 6.562 kcal/mol.

σ = 24

Heat of Formation

Settle et al. (1) measured the heat of formation of gaseous MoF₆ by direct combination of its elements in a nickel bomb calorimeter. Their result was $\Delta H_f^\circ(\text{MoF}_6, g) = -372.4 \pm 0.2 \text{ kcal/mol}$. This value is adopted in the tabulation.

Heat Capacity and Entropy

Tanner and Duncan (2) investigated the Raman spectra of liquid MoF₆, and their results indicated that the structure of the molecule was a regular octahedron with O_h symmetry rather than an unsymmetrical structure as reported by Braune and Pinnow (3) from electron diffraction studies. The Mo-F bond length is from the electron diffraction studies of Nazarian (4). Individual moments of inertia are I_A = I_B = I_C = 4.268 × 10⁻³⁸ g cm².

Several infrared (5, 6, 7) and Raman (5, 7) studies of MoF₆ have been reported. The vibrational frequencies reported for MoF₆ from these studies are in good agreement except for the infrared and Raman inactive ν_6 vibration. Burke et al. (5) and Hellberg et al. (6) derived $\nu_6 = 234 \text{ cm}^{-1}$, while Claassen et al. (7) assigned $\nu_6 = 130 \text{ cm}^{-1}$ and Gaunt (6) assigned $\nu_6 = 240 \text{ cm}^{-1}$. Weinstock and Goodman (8) recently analyzed the infrared and Raman data for MoF₆ and assigned $\nu_6 = 122 \text{ cm}^{-1}$.

Osborne et al. (10) calculated $S^\circ = 62.06 \pm 0.06 \text{ gibbs/mol}$ for liquid MoF₆ at 298.15°K from their low temperature thermal data. Combining this with ΔS° , they obtained $S^\circ = 83.75 \pm 0.10 \text{ gibbs/mol}$ for the ideal gas at 298.15°K. Accepting the assignments of Weinstock and Goodman (8), we calculate $S_{298.15}^\circ = 83.76 \text{ gibbs/mol}$, which is in excellent agreement with the thermal results. The other assignments given above for ν_6 all lead to ideal gas entropies that are lower than the thermal results. Therefore, the assignments given by Weinstock and Goodman (8) are adopted here.

Dec. 31, 1960 Sept. 30, 1965

SULFUR HEXAFLUORIDE (SF₆) (IDEAL GAS)

MOL. WT. = 146.0544

Point Group O_h

S_{298.15} = 69.713 cal. deg.⁻¹ mole⁻¹

Ground State Quantum Weight = 1

ΔH°_f 0 = -288.46 ± 0.24 kcal. mole⁻¹

ΔH°_f 298.15 = -291.79 ± 0.24 kcal. mole⁻¹

Vibrational Frequencies and Degeneracies

ω, cm. ⁻¹	ω, cm. ⁻¹	ω, cm. ⁻¹
770 (1)	345 (3)	
640 (2)	615 (3)	
522 (3)	947 (3)	

Bond Length = 1.564 Å

Bond Angle: F-S-F = 90°

Product of the Moments of Inertia: I_AI_BI_C = 29,400 X 10⁻¹¹⁷ g.³ cm.⁶

σ = 24

Heat of Formation.

P. A. O. O'Hare, J. L. Settle, and W. N. Hubbard, Preprint of Paper XIV on Fluorine Bomb Calorimetry, July, 1965, measured the enthalpy of combustion of rhombic sulfur in fluorine. Their result yields ΔH°_f 298 = -291.79 ± 0.24 kcal. mole⁻¹. P. Gross, C. Hayman, and L. L. Levi, XVIII Intern. Congr. Pure and Appl. Chem., Abstr., 1, 30 (1959), reported -289.5 kcal. mole⁻¹ also based on direct combination of the elements. O'Hare, Settle, and Hubbard mentioned a private communication from Dr. Gross indicating -289.5 kcal. mole⁻¹ may be in error due to oxygen in the fluorine used and preliminary results of a redetermination are in better agreement with -291.79 kcal. mole⁻¹. D. M. Yost and W. H. Clausen, J. Am. Chem. Soc. 55, 887 (1933) determined -262 kcal. mole⁻¹, again by direct reaction of the elements, which now appears too low. The work of O'Hare et al., loc. cit., is adopted.

Heat Capacity and Entropy.

V. C. Ewing and L. E. Sutton, Trans. Faraday Soc. 59, 124 (1963) measured the bond length adopted here by the electron diffraction technique. Earlier less accurate work by the same method by H. Braune and S. Knoke, Z. physik. Chem. B21, 297 (1933) and L. O. Brockway and L. Pauling, Proc. Nat. Acad. Sci. USA 19, 68 (1933) is in agreement within experimental error. T. E. Norys, Ber. Bunsenges Physik. Chem. 68, 277 (1964) reviewed the literature on Raman and infrared spectra. Frequencies given here differ slightly from his selection because more weight was given to the Raman frequencies of C. W. Oullikaon, J. R. Nielsen, and A. T. Stair, Jr., J. Mol. Spectroscopy 1, 151 (1957). Calculated functions by Morry loc. cit. are in reasonable agreement with the present work.

A. Eucken and E. Schröder, Z. physik. Chem. 41B, 307 (1938) measured low temperature thermal data from which K. K. Kelley and E. O. King, U. S. Bur. Mines Bull. 592 (1961) calculated s°₂₉₈ = 70.3 ± 0.7 cal. mole⁻¹ deg.⁻¹ which agrees within experimental error with the spectroscopic result.

The three principal moments of inertia are I_A = I_B = I_C = 3.0863 X 10⁻³⁸ g. cm.²

TUNGSTEN HEXAFLUORIDE (WF₆) (LIQUID)

ΔH°_{298,15} = -417.87 ± 0.5 kcal/mol
ΔH° = 0.980 kcal/mol
ΔH° = 6.465 ± 0.08 kcal/mol

Heat of Formation.

The adopted heat of formation, -417.87 kcal/mol, is calculated from the chosen ΔH°_{298,15} = 6.465 ± 0.08 kcal/mol with ΔH°₂₉₈(WF₆,g) = -411.5 ± 0.4 kcal/mol using all JANAF functions. The value of ΔH°_{298,15} is obtained by corrected 2nd law analysis of vapor pressure data^{6,7,8} which are given in the vaporization section of this table.

O. E. Myer and A. P. Brady¹ measured calorimetrically ΔH°₂₉₈ = -150.1 kcal/mol for the reaction
WF₆(l) + 8 NaOH(500H₂O) → Na₂WO₄(4900H₂O) + 8NaF(500H₂O) + 8NaF(500H₂O)²
metrically ΔH°₂₉₈ = -13.8 kcal/mol for the reaction WO₃(c) + 2 NaOH(500H₂O) → Na₂WO₄(4200H₂O) + H₂O(l). Based on these data and auxiliary data for NaOH(aq)^{3,9}, NaF(aq)^{3,10} and Na₂WO₄(aq)⁴, we obtain ΔH°₂₉₈ = -138.2 kcal/mol for WF₆(l) + 8 NaOH(500H₂O) → WO₃(c) + 3 H₂O(l) + 8 NaF(500H₂O). This leads to ΔH°₂₉₈(WF₆,l) = -418.9 ± 1 kcal/mol which is in good agreement with the value adopted.

Heat Capacity and Entropy.

The heat capacity, 40.5 gibbs/mol, is obtained from a graph of the Cp versus temperature curve determined calorimetrically by E. F. Westrum, Jr.⁵
The entropy, S°₂₉₈ = 59.584 eu, is calculated from the chosen ΔH°_{298,15} = 6.465 kcal/mol with S°₂₉₈(WF₆,g) = 81.504 eu using all JANAF functions.

Melting Data.

Melting point and heat of melting have been reported by the following investigators, and their results are summarized below. Ruff and Ascher's value, 2.40 kcal/mol, is too high because they did not know of the existence of a solid-solid transition⁵ at 264.7°K with ΔH° = 2.087 kcal/mol. Westrum's data are adopted in the tabulation.

Investigator ⁵	Method	Melting Point (°K)	ΔH° ^m (kcal/mol)
Westrum ⁵	Calorimetric	275.2	0.940
Ruff and Ascher ⁷	Vapor pressure	275.4	2.400*
Barber & Cady ⁸	Warming curve	275.1	0.500
Cady & Hargreaves ⁶	Vapor pressure	275.2	0.420*

*This value is the difference between the 2nd law heats of sublimation and vaporization without correction for ΔCp° for both processes.

Vaporization Data.

Second law analyses of the data^{6,7,8}, neglecting corrections for nonideality of the vapor, are summarized below. The value of ΔH°₂₉₈ = 6.37 kcal/mol (ΔH°_{298,15} = 6.465 kcal/mol) is selected in the tabulation.

Investigator ⁷	Temp. Range (°K)	No. of Points	Boiling Point (°K)	ΔH° _{v,298} (kcal/mol)	ΔS° _{v,298} (eu)
Ruff and Ascher ⁷	275 - 287.5	5	290.7 ± 0.2	6.30 ± 0.12	21.70
Barber and Cady ⁸	285 - 324.5	16	290.2 ± 0.05	6.37 ± 0.01	21.94
Cady and Hargreaves ⁶	275 - 290	Equation	290.3 ± 0.05	8.12	21.09

*From second law analysis using ΔCp° = -12.4 gibbs/mol

TUNGSTEN HEXAFLUORIDE (WF₆)

(IDEAL GAS)

OFW = 297.8404 F₆^W

Point Group O_h

ΔH_f⁰ = -409.4 ± 0.4 kcal/mol

S_{298.15} = 81.504 gibbs/mol

ΔH_f⁰_{298.15} = -411.5 ± 0.4 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

W, cm ⁻¹	W, cm ⁻¹
769 (1)	256 (3)
670 (2)	322 (3)
712 (3)	216 (3)

Bond Distance: W-F = 1.83 Å

Bond Angle: F-W-F = 90°

Product of the Moments of Inertia: I_AI_BI_C = 7.54576 x 10⁻¹¹³ g³ cm⁶

σ = 24

Heat of Formation

P. A. O. O'Hare and W. N. Hubbard, J. Phys. Chem. **70**, 3353 (1966), determined the heat of formation, ΔH_f⁰₂₉₈(WF₆) = -411.5 ± 0.4 kcal/mol, by combustion of tungsten in fluorine in a bomb calorimeter. This value is adopted in the tabulation.

Heat Capacity and Entropy.

The molecular configuration and vibrational frequencies were obtained from the infrared and Raman spectroscopic studies by J. Gaunt¹, T. O. Burke, D. P. Smith and A. H. Nielsen², K. N. Tanner and A. B. P. Duncan³, K. H. Claassen⁴, based on the preliminary result of V. Schomaker, M. Kimura and B. Weinstein⁵ who determined the bond distance by electron diffraction. J. Gaunt⁶ derived W-F = 1.89 Å from correlation with other hexafluorides and a valence force constant calculation. The three principal moments of inertia are I_A = I_B = I_C = 4.22572 x 10⁻³⁸ g cm².

	$\Delta H_g^0 298.15 = 99.5 \pm 0.4$ kcal. mole ⁻¹

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The heat capacity below 298°K. was obtained by smoothing graphically the data of G. Duyckaerts, *Physica* **6**, 401 (1939) and W. H. Keesom and B. Kurrelmeyer, *Physica*, **6**, 633 (1939) over the range 1° - 20°K.; P. E. Simon and R. C. Swain, *Z. Physik. Chem.* **28B**, 189 (1935) (30-220°K.), A. Eucken and H. Verth, *Z. Physik. Chem.* **188**, 152 (1930) (17-206°K.) and K. K. Kelley, *J. Chem. Phys.* **11**, 16 (1943) (55-295°K.). This data on integration yielded $S_{298.15}^0 = 6.529$ starting with $S_1^0 = 0.0003$ cal. deg.⁻¹ mole⁻¹. The heat capacity and enthalpy data above room temperature are extensive and the heat capacities and enthalpies chosen by R. Hultgren, R. L. Orr, P. D. Anderson and K. K. Kelley, "Selected Values of Thermodynamic Properties of Metals and Alloys" John Wiley and Sons, Inc., New York 1963, were adopted here. These values have a sharp peak in the heat capacity curve at the Curie point* and through this region follow closely the work of P. R. Pallister, *J. Iron Steel Inst.* **161**, 87 (1949). This data has recently been corroborated using a pulsed heating technique by D. C. Wallace, P. H. Sidles and G. C. Danielson, *J. App. Phys.* **31**, 168 (1960). It should be noted that there is some disagreement between the heat capacities chosen and the enthalpies measured by P. D. Anderson and R. Hultgren, *Trans. Met. Soc. AIME*, **224**, 842 (1962). The measured values lie consistently above the chosen enthalpies in the range 298-900°K. by from 30 to 60 calories, however the chosen values are considered to be the more reliable. The δ -iron heat capacities adopted here have recently been substantiated confirmed by W. A. Dench and O. Kubaschewski, *J. Iron Steel Inst.* (London) **201**, 140 (1963).

Transition Data.

The enthalpies of the α - δ transition at 1184°K. and the δ - γ transition at 1665°K. were also taken from Hultgren et al. loc. cit.

Melting Data.

The temperature and heat of melting were those adopted by Hultgren et al. loc. cit.

Heat of Sublimation.

The value adopted is from a critical second and third law analysis of the data of 14 investigators over gamma-iron and liquid iron. See the $\Delta H_{\text{sub}}(g)$ table for details.

*See W. P. Giauque, G. E. Brodale, R. A. Fisher and E. W. Hornung, *J. Chem. Phys.* **42**, 1 (1965) for the definition of "permt".

IRON (Fe)

(LIQUID)

AT. WT. = 55.85

$$\Delta H_f^{298.15} = 3.138 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{298.15} = 3.650 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^{298.15} = 83.679 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^{298.15} = 8.195 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1809^\circ \text{K.}$$

$$T_b = 3145.4^\circ \text{K.}$$

Heat of Formation.

The $\Delta H_f^{298.15}$ was obtained from that of the crystal by adding ΔH_m and the difference between $H_{1809} - H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase was that chosen by R. Hultgren, R. L. Orr, F. D. Anderson and K. K. Kelley, "Selected Values of Thermodynamic Properties of Metals and Alloys" John Wiley and Sons, Inc., New York (1963).

Melting Data.

See Fe(c) for details.

Vaporization Data.

The boiling point was calculated from the adopted thermodynamic functions and the chosen heat of sublimation at 298°K. so that the free energy function calculated by integration of the crystal liquid data or by statistical methods from the gas phase were equal at the boiling point.

Heat of Formation.

The heat of formation is the heat of sublimation at 298°K. which was obtained by second and third law analysis of the following vapor pressure data.

Method	Points	Ref.	$\Delta H^{\circ}_{298.15}$ 2nd law kcal. mole ⁻¹	$\Delta H^{\circ}_{298.15}$ 3rd law kcal. mole ⁻¹	Drift in 3rd law cal. deg. ⁻¹ mole ⁻¹

IRON DIHYDROXIDE (Fe(OH)₂) (CRYSTAL)

ΔH_f^o = Unknown
 ΔH_f^o_{298.15} = -137.2 ± 0.7 kcal/mol
 ΔH_m^o = Unknown
 ΔH_{298.15} = 58.2 kcal/mol

S_{298.15} = [21 ± 2] gibbs/mol

T_m = Unknown

Heat of Formation.

The heat of combustion of Fe(OH)₂(c), according to the chemical reaction Fe(OH)₂(c) + 1/4 O₂(g) = 1/2 Fe₂O₃(c) + H₂O(l), was determined to be -29.8 ± 0.65 kcal/mol by R. Fricke and S. Rühl, Z. anorg. allgem. chem. 251, 414 (1943). From this data the heat of formation (ΔH_f^o_{298.15}) was evaluated to be -137.2 ± 0.7 kcal/mol. which was adopted here.

The enthalpy changes for the following three reactions were determined by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882 - 1886:

Reaction	ΔH _r ^o , kcal/mol
1. FeCl ₂ (c) = FeCl ₂ (400 H ₂ O)	-17.9
2. FeCl ₂ (200 H ₂ O) + H ₂ SO ₄ (200 H ₂ O) = FeSO ₄ (200 H ₂ O) + 2 HCl(100 H ₂ O)	-3.6
3. FeSO ₄ (aq.) + 2KOH(aq.) = Fe(OH) ₂ (c) + K ₂ SO ₄ (aq.)	-6.34

Using ΔH_f^o_{298.15} = -81.7 kcal/mol for FeCl₂(c) and those for the other compounds in aqueous solution (assuming aq. = 200 H₂O in Reaction 3) obtained from D.D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," NBS Technical Note 270-1, National Bureau of Standards, 1965, the heat of formation (298.15°K) for Fe(OH)₂(c) was derived as -135.8 kcal/mol which agrees reasonably with the adopted value.

Heat Capacity and Entropy.

The heat capacities, 298.15 - 700°K, and S_{298.15} were estimated by comparison with those for FeCl₂(c), CaCl₂(c) and Ca(OH)₂(c). The Cp values above 700°K were obtained by graphical extrapolation of the Cp curve plotted using the above Cp values.

Heat of Sublimation.

The value of ΔH_{298.15} was calculated as the difference between ΔH_f^o_{298.15} for Fe(OH)₂(g) and Fe(OH)₂(c).

Heat of Formation

The equilibrium constants, at temperatures between 1300 and 1460°C, for the chemical reaction $\text{Fe}(\text{c}) + 2\text{H}_2\text{O}(\text{g}) = \text{Fe}(\text{OH})_2(\text{g}) + \text{H}_2(\text{g})$, were determined by G. R. Belton and F. D. Richardson, Trans. Faraday Soc. 58, 1562 (1962). Using these data, the enthalpy change (ΔH_f°) of the reaction is evaluated to be 35.53 ± 3.0 and 35.57 kcal/mol by the second and third law method, respectively. Based on the third law value for ΔH_f° , the heat of formation (ΔH_f°) for $\text{Fe}(\text{OH})_2(\text{g})$ is calculated to be $-79 \pm 0.5 \text{ kcal/mol}$.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that for $\text{B}(\text{OH})_2(\text{g})$. The Fe-O bond distance is taken from $\text{FeO}(\text{g})$. The O-H bond distance and Fe-O-H bond angle are estimated from those for $\text{H}_2\text{O}(\text{g})$. The vibrational frequencies, and electronic levels and quantum weights are obtained by comparison with those for $\text{B}(\text{OH})_2(\text{g})$ and $\text{FeCl}_2(\text{g})$, respectively. These values are adjusted to give reasonable second and third law agreements. The three principal moments of inertia are: $I_A = 2.658 \times 10^{-40}$, $I_B = 1.864 \times 10^{-36}$ and $I_C = 1.890 \times 10^{-36} \text{ g cm}^2$.

Heat of Formation.

P. Schindler, W. Michaelis and W. Feltmeyer, *Helv. Chim. Acta*, **46**, 444 (1963), investigated the solubility of aged Fe(OH)₃ precipitates by determining the Fe⁺⁺⁺ and H⁺ ion concentration of solution in contact with the solid phase. The ion concentration was measured by the EMF method at the constant ionic strength 3M NaClO₄ (solution). The precipitates were investigated by X-ray and electron microscope methods. The equilibrium constant was derived as log [Fe⁺⁺⁺] [H⁺]⁻³ = log K = 3.55 ± 0.1 for amorphous inactive hydroxide at 25°C. From these data the quantity log Ka = -39.1 ± 0.2 was evaluated where Ka is the solubility product of Fe(OH)₃. The Gibbs energy change (ΔHf°_{298.15}) of the reaction Fe(OH)₃(c) = Fe⁺⁺⁺(aq) + 3OH⁻(aq) was calculated to be 53.34 ± 0.27 kcal/mol. Using S°_{298.15} = 70.1 and -2.57 gibbs/mol for Fe⁺⁺⁺(aq) and OH⁻(aq), respectively, and an estimated S°_{298.15}(Fe(OH)₃, c) = 25 gibbs/mol, the enthalpy change (ΔHf°_{298.15}) of the reaction is calculated to be 22.69 kcal/mol, according to the relationship ΔH = ΔG + TΔS. The entropy values for Fe⁺⁺⁺ and OH⁻ ions were obtained from "Selected Values of Chemical Thermodynamic Properties," Circular 500, National Bureau of Standards, 1952, and NBS Technical Note 270-1 by D. D. Wagman and co-workers, 1965, respectively. Based on ΔHf°_{298.15}(Fe⁺⁺⁺, aq) = -11.4 and ΔHf°_{298.15}(OH⁻, aq) = -54.97 kcal/mol, taken from the same source, the heat of formation (ΔHf°_{298.15}) for Fe(OH)₃(c) was evaluated to be -199 ± 3 kcal/mol, which was adopted here.

The divergent values for solubility product (SP) of Fe(OH)₃ found in the literature may be due not only to the various forms of precipitate, but also to the tendency to form colloidal solutions. The SP values for Fe(OH)₃ were also reported by Evans and Pryor, *J. Chem. Soc.* **5157** (1949); Kriukor and Awsejwitsch, *Z. Elektrochem.* **39**, 884 (1935); Ruff and Hirsch, *Z. Anorg. Chem.* **146**, 338 (1925); Britton, *J. Chem. Soc.* **2148** (1925); and Jellinek and Gordan, *Z. Phys. Chem.* **112**, 207 (1924).

The enthalpy changes (ΔHf°_{298.15}) for the reactions: (1) FeCl₃(aq) + 3NaOH(aq) = Fe(OH)₃(c) + 3NaCl(aq) and (2) FeCl₃(c) = FeCl₃(aq) were determined to be -24.50 and -31.68 kcal/mol, respectively, by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882 - 1886. Assuming the aqueous solutions all contain 200 mol of H₂O, the heat of formation (ΔHf°_{298.15}) for Fe(OH)₃ was calculated as -196.9 kcal/mol from Reactions (1) and (2). The ΔHf°_{298.15} values for NaOH(aq) and NaCl(aq) were obtained from V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NBS-RS-2, National Bureau of Standards, 1965, and JANAP ΔHf°_{298.15} values for NaOH(c) and NaCl(c).

Heat Capacity and Entropy.

The heat capacities, 298.15 - 1000°K, were estimated by comparison with those for Fe₂O₃(c), Fe₂O₃(c) and B(OH)₃(c). The Cp values above 1000°K were obtained by graphical extrapolation. The S°_{298.15}(Fe(OH)₃, c) value was estimated by comparison with that for B(OH)₃(c).

 $\Delta H_f^\circ =$ Unknown $\Delta H_f^\circ_{298.15} = -25 \pm 4$ kcal/mol $\Delta H^\circ = 0.2$ kcal/mol $\Delta H_m^\circ = [10.7]$ kcal/mol $\Delta H_{298.15}^\circ$ (to monomer) = [46] kcal/mol $\Delta H_{298.15}^\circ$ (to dimer) = [52] kcal/mol

Heat of Formation.

The chemical equilibrium of the decomposition of FeI₂(c), 771.15 — 958.15°K, has been studied by W. E. Zaugg and N. W. Gregory, J. Phys. Chem. 70, 488 (1966). Using the reported partial pressures for I₂(g), the enthalpy change ($\Delta H_{298.15}^\circ$) for the reaction FeI₂(c) = Fe(c) + I₂(g) was evaluated by both the second and third law methods to be 39.79 ± 1.0 and 39.69 ± 0.3 kcal/mol, respectively. Based on the third law $\Delta H_{298.15}^\circ$ value, the heat of formation ($\Delta H_{298.15}^\circ$) for FeI₂(c) was calculated as -25 kcal/mol which was adopted here.

The enthalpy change for the reaction FeI₂(c) = Fe⁺⁺(aq) + 2 I⁻(aq) was determined to be -19.48 ± 0.03 kcal/mol by P. Paoletti, A. Sabatini and A. Vacca, Trans. Faraday Soc. 61, 2417 (1965), using a solution calorimetric method. Adopting $\Delta H_{298.15}^\circ = -21.3$ and -13.19 kcal/mol for Fe⁺⁺(aq) and I⁻(aq), respectively, the value of $\Delta H_{298.15}^\circ$ (FeI₂, c) was derived as -28.22 ± 1 kcal/mol. The value of $\Delta H_{298.15}^\circ$ (I⁻, aq) was taken from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Part 1, Technical Note 270-1, National Bureau of Standards, 1965. The value of $\Delta H_{298.15}^\circ$ (Fe⁺⁺, aq) was derived from heats of solution and formation for FeCl₂(c).

The heats of solution of Fe(c), I₂(c) and FeI₂(c) in aqueous Br₂-KBr solution were measured by W. Hieber and A. Moerner, Z. Elektrochem. 40, 287 (1936), using an ice calorimeter. From the results obtained the heat of formation for FeI₂(c) was reported as -30.1 kcal/mol.

Heat Capacity and Entropy.

The heat capacities, 343.15 — 773.15°K, were measured by F. L. Oetting and N. W. Gregory, J. Phys. Chem. 65, 173 (1961). The Cp values at temperatures below 343.15 and above 773.15°K were estimated by graphical extrapolation. The low temperature heat capacities, 11-130°K, were determined by O. Miljutin and E. A. Parfenova, Phys. Trans. Ukrain. Acad. Sci., 81 (1940). These data appear to be inadequate for the derivation of the entropy at 298.15°K. The value of S_{298.15} adopted was calculated from the entropy change, $\Delta S_{298.15}^\circ = 28.7$ eu, for the decomposition reaction FeI₂(c) = Fe(c) + I₂(g), obtained by the second law analysis of the equilibrium pressure data reported by W. E. Zaugg and N. W. Gregory, J. Phys. Chem. 70, 486 (1966).

Transition Data.

A minor transition in the vicinity of 370°C (360-385°C) has been reported by F. L. Oetting and N. W. Gregory, loc. cit. Subsequent studies by T. J. Mydeven, Ph. D. Thesis, University of Washington, Seattle, Wash., 1964, have shown the magnitude of the transition to be sensitive to trace amounts of impurities, but the nature of the transition has not been clearly established. A magnetic transition at 10°K was reported by H. Bizette, C. Terrier and B. Taal, Compt. rend. 245, 507 (1957). The ΔH° value was evaluated from the heat capacity - temperature plot given by F. L. Oetting and N. W. Gregory, loc. cit.

Melting Data.

Tm was reported by W. Fischer and R. Guehr, Z. anorg. allgem. Chem. 222, 303 (1935). ΔH_m° was estimated by comparison with that for FeBr₂(c).

Heat of Sublimation.

$\Delta H_{298.15}^\circ$ (to monomer) is calculated as the difference between $\Delta H_{298.15}^\circ$ for FeI₂(g) and FeI₂(c). $\Delta H_{298.15}^\circ$ (to dimer) was calculated as the difference between those for FeI₄(g) and 2 FeI₂(c).

ΔH_{f,298.15}° = [16.969] kcal/mol

ΔH_m° = [10.7] kcal/mol

ΔH_v° = [25.0] kcal/mol

S°_{298.15} = [46.720] gibbs/mol

T_m = 860 ± 2° K

T_b = [1366] °K

Heat of Formation.

The heat of formation (ΔH_{f,298.15}°) was obtained from ΔH_{f,298.15}° (c) by adding ΔH_m° and the difference between H_m° - H_l°_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was assumed to be constant in the temperature range from 298.15 to 2000°K. The value of C_p was calculated on an assumption that C_p = 9.0 gibbs/g-atom for FeI₂(l). The entropy was obtained in a manner analogous to that of the heat of formation.

Vaporization Data.

T_b is the temperature at which the vapor pressure of FeI₂(g) and Fe₂I₄(g) over FeI₂(l) equals one atmosphere. The value of ΔH_v° is derived from the vapor composition and the heats of vaporization of FeI₂(l) to monomer and dimer at T_b.

Heat of Formation.

The chemical equilibria in the Fe-C-O and Fe-H-O systems have been studied by many investigators. Using the reported equilibrium constants for the following two reactions (1) Fe_{0.947}O(c) + CO(g) = 0.947Fe(c) + CO₂(g) and (2) Fe_{0.947}O(c) + H₂(g) = 0.947Fe(c) + H₂O(g), the corresponding enthalpy changes (ΔH_f⁰) were evaluated by both the second and third law methods. Based on the third law values for ΔH_f⁰, the ΔH_f⁰ 298.15 (Wüstite, c) values were also calculated. The results obtained are presented as follows.

Investigator	Reaction	Temperature, °K.	Second Law Value	Third Law Value	ΔH _f ⁰ 298.15 ¹
Eastman ¹	(1)	873.2-1273.2	-3.80 ± 0.01	-4.01	-63.63

Britzke et al. ⁴	(3)	1123.0-1473.0	-129.08 ± 0.18	-126.28	-63.14

¹ E. D. Eastman, J. Am. Chem. Soc. 44, 975 (1922).

² E. D. Eastman and R. W. Evans, J. Am. Chem. Soc. 46, 888 (1924). The K_p value at 1273.2°K. for reaction (1) is rejected by a statistical criterion.

³ P. H. Emmett and J. P. Schultz, J. Am. Chem. Soc. 52, 4268 (1930).

⁴ E. V. Britzke, A. F. Kapustin and T. I. Schachkins, Z. anorg. allgem. Chem. 219, 287 (1954). The K_p value at 1123°K. for reaction (2) is rejected by a statistical criterion.

⁵ W. E. Joniny and D. W. Murphy, Ind. Eng. Chem. 23, 394 (1931). The K_p values at 1590 and 1645°K. are rejected by a statistical criterion.

⁶ J. Chipman and S. Marshall, J. Am. Chem. Soc. 62, 299 (1940).

Britzke et al. also determined the equilibrium pressures for the reaction (3) 1.894 Fe(c) + O₂(g) = 2Fe_{0.947}O(c). The corresponding ΔH_f⁰ 298.15 for Wüstite was evaluated based on the third law value for ΔH_f⁰ 298.15. The adopted value of ΔH_f⁰ 298.15 (Wüstite, c) is the weighted average of the ΔH_f⁰ 298.15 listed in the above table.

Heat Capacity and Entropy.

The low temperature (54.37-298.16°K.) heat capacities (C_p) were measured by S. S. Todd and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3894 (1951). The high temperature (298-1650°K.) heat capacities were determined by J. P. Coughlin, E. O. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3891 (1951). The two sets of C_p data were plotted and joined smoothly at 298°K. The C_p values above 1650°K. were obtained by graphical extrapolation. The low temperature (70.7-279.8°K.) C_p's were also reported by R. W. Miller, J. Am. Chem. Soc. 51, 215 (1929). S_{298.15} was derived from the low temperature heat capacities, based on S_{298.15}⁰ = 0.696 cal. deg.⁻¹ mole⁻¹. S. S. Todd and K. R. Bonnickson, loc. cit. added 0.41 e.u., the amount calculated for completely random distribution of the vacant Fe spaces in the Wüstite lattice. However, the free energy functions derived from S_{298.15}⁰ = 0.696 e.u. give better agreement between second and third law values for ΔH_f⁰ than those derived from S_{298.15}⁰ = 1.11 e.u. Therefore the value 0.41 e.u. was not added here.

FeO

$\Delta H^\circ_f 0$ = Unknown
 $\Delta H^\circ_f 298.15$ = [-65.02] kcal. mole⁻¹
 ΔH°_m = [5.75] kcal. mole⁻¹
 $\Delta H^\circ_g 298.15$ = [121.62] kcal. mole⁻¹

$S^\circ_{298.15}$ = [14.52] cal. deg.⁻¹ mole⁻¹
 T_m = [1850]*°K.

Heat of Formation.

The value of $\Delta H^\circ_f 298.15$ for FeO(c) was derived based on an assumption that at 1650°K., ΔH°_f (FeO, c) = ΔH°_f (FeO, l). From the value $\Delta H^\circ_f 1650$ (FeO, c) = -39.77 kcal. mole⁻¹, $\Delta H^\circ_f 1650$ (FeO, c) was calculated to be -63.97 kcal. mole⁻¹, yielding $\Delta H^\circ_f 298.15$ (FeO, c) = -65.02 kcal. mole⁻¹.

Heat Capacity and Entropy.

The C_p values were estimated assuming C_p (FeO, c) = C_p (Wüstite, c) + 0.053 C_p (Fe, c). The C_p values obtained were plotted. The adopted C_p points were taken from the smoothed C_p curve. $S^\circ_{298.15}$ for FeO(c) was calculated as S° (FeO, c) = S° (Wüstite, c) + 0.053 S° (Fe, c) + ΔS° (mixing) where ΔS° is the entropy of mixing (0.41 cal. deg.⁻¹ mole⁻¹).

Melting Data.

T_m is assumed to be the same as that for Wüstite. The difference between $\Delta H^\circ_f 1650$ for FeO(l) and FeO(c) is ΔH°_m .

Heat of Sublimation.

$\Delta H^\circ_g 298.15$ is calculated as the difference between $\Delta H^\circ_f 298.15$ for FeO(g) and FeO(c).

Iron Oxide (FeO)

(Liquid) Mol. wt. = 71.8464

FeO

MOL. WT. = 71.8464

(LIQUID)

IRON OXIDE (FeO)

$S_{298.15}^{\circ} = 18.029 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = [1650]^{\circ}\text{K.}$
 $T_d = [3687]^{\circ}\text{K.}$
 $\Delta H_f^{\circ} 298.15 = [-59.642] \text{ kcal. mole}^{-1}$
 $\Delta H_m^{\circ} = [5.75] \text{ kcal. mole}^{-1}$
 $\Delta H_f^{\circ} 298.15$ was evaluated based on an assumption that the heat of melting of Wüstite, ΔH_m° represents the enthalpy change of the reaction $\text{FeO}_{0.947}(\text{c}) = 0.947 \text{ FeO}(\text{l}) + \frac{0.053}{2} \text{O}_2(\text{g})$. In other words, during melting the Wüstite releases $\text{O}_2(\text{g})$ and converts to $\text{FeO}(\text{l})$.
 The heat of formation ($\Delta H_f^{\circ} 298.15$) was evaluated based on an assumption that the heat of melting of Wüstite, ΔH_m° represents the enthalpy change of the reaction $\text{FeO}_{0.947}(\text{c}) = 0.947 \text{ FeO}(\text{l}) + \frac{0.053}{2} \text{O}_2(\text{g})$. In other words, during melting the Wüstite releases $\text{O}_2(\text{g})$ and converts to $\text{FeO}(\text{l})$.
 The heat capacity and entropy.
 The enthalpy changes ($H_f^{\circ} - H_{298.15}^{\circ}$) of liquid iron oxide were determined by J. P. Coughlin, E. O. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3691 (1951). The C_p (FeO, l) was derived as $16.3 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$. This value was adopted as the heat capacity for $\text{FeO}(\text{l})$ up to 4000°K. A glass transition temperature was assumed at 1100°K. $S_{298.15}^{\circ}$ (FeO, l) was calculated based on an assumption that the entropy of melting of Wüstite represents also the entropy change of the reaction, $\text{FeO}_{0.947}(\text{c}) = 0.947 \text{ FeO}(\text{l}) + \frac{0.053}{2} \text{O}_2(\text{g})$. From the entropy of melting, $\Delta S_m^{\circ} 1650 = 4.539 \text{ e.u.}$, the value $S_{298.15}^{\circ}$ (FeO, l) = 18.029 e.u. was derived.

Heat Capacity and Entropy.

The enthalpy changes ($H_f^{\circ} - H_{298.15}^{\circ}$) of liquid iron oxide were determined by J. P. Coughlin, E. O. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3691 (1951). The C_p (FeO, l) was derived as $16.3 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$. This value was adopted as the heat capacity for $\text{FeO}(\text{l})$ up to 4000°K. A glass transition temperature was assumed at 1100°K. $S_{298.15}^{\circ}$ (FeO, l) was calculated based on an assumption that the entropy of melting of Wüstite represents also the entropy change of the reaction, $\text{FeO}_{0.947}(\text{c}) = 0.947 \text{ FeO}(\text{l}) + \frac{0.053}{2} \text{O}_2(\text{g})$. From the entropy of melting, $\Delta S_m^{\circ} 1650 = 4.539 \text{ e.u.}$, the value $S_{298.15}^{\circ}$ (FeO, l) = 18.029 e.u. was derived.

Melting Data.

The melting point (T_m) for Wüstite ($\text{FeO}_{0.947}$, c) has been reported by many investigators. However, the composition of the liquid state of Wüstite was not identified. An assumption was made that during melting the reaction $\text{FeO}_{0.947}(\text{c}) = 0.947 \text{ FeO}(\text{l}) + \frac{0.053}{2} \text{O}_2(\text{g})$ occurs. Hence the related thermodynamic properties were derived.

Decomposition Temperature.

T_d is the temperature at which ΔG_f° equals zero.

Heat of Formation

The heat of formation for FeO(g) is not well established at the present time. The values of ΔH_f° (FeO, g) derived from the following reactions: (1) $\text{FeO(g)} = \text{Fe(g)} + \text{O(g)}$, (2) $\text{FeO(g)} = \text{Fe(g)} + 1/2 \text{O}_2(\text{g})$, and (3) $\text{FeO(l)} = \text{FeO(g)}$, are not in agreement. There are three D° (Fe-O) values reported for reaction (1). The enthalpy change for reaction (2) was evaluated based on the partial pressure data ($P_{\text{FeO}}/P_{\text{O}_2}$) = 0.2 at 1600°C, measured by Washburn⁴, using a mass spectrometric method, U. S. Atomic Energy Commission, UCRL-10991, August 1963, and $P_{\text{O}_2} = 1.66 \times 10^{-6}$ atm reported by L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 82, 796 (1960). The enthalpy value for reaction (3) was calculated based on the reported value, $\Delta H_f^{298.15} = 96.096 \text{ kcal/mol}$ determined by Burtsev, Karasev and Samarin⁵. The results obtained are presented as follows. The value of $\Delta H_f^{298.15}$ for FeO(g) adopted is $60 \pm 5 \text{ kcal/mol}$.

Investigator	Reaction	Method	$\Delta H_f^{298.15}$ kcal/mol	$\Delta H_f^{298.15}$ kcal/mol

3. A. Lagerqvist and L. Hult, Z. Naturforsch. 8a, 483 (1953). D° was derived from atomic spectra of Fe produced by acetylene-air flame method.

4. J. Washburn UCRL 10991, August 1963, obtained from L. Brewer, private communication, October 18, 1966.

5. V. T. Burtsev, R. A. Karasev and A. M. Samarin, Fiz.-Khim. Osnovy Proizv. Stali, Akad. Nauk SSSR, Inst. Met., Tr. 5-01 (Shestol) Konf., Moscow, 366 (1961); published in 1964.

Heat Capacity and Entropy

Since the ground state configuration is due to Fe^{++} in a ligand field, it was assumed to be the same as that of $\text{FeCl}_2(\text{g})$ reported by C. W. DeLoock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966). The electronic levels and quantum weights were estimated by comparison with those of $\text{FeCl}_2(\text{g})$. The values of ω_e and $\omega_e x_e$ were taken from G. Herzberg, loc. cit. The bond distance was calculated according to the method suggested by K. M. Ouguenheimer, Proc. Phys. Soc. (London) 55, 456 (1946), assuming FeO(g) as a polar molecule. The value of B_e was calculated by use of the relationship $B_e = (2.79976 \times 10^{-19})/I$ where I is the moment of inertia of FeO(g). The value of χ_e was derived from ω_e , $\omega_e x_e$ and B_e by the method suggested by G. Herzberg, loc. cit. The principal moment of inertia is $6.6899 \times 10^{-39} \text{ g cm}^2$.

IRON SULFATE (FeSO₄)

(CRYSTAL)

OPW = 151.9086

ΔHf° = -219.7 ± 2 kcal/mol
 ΔHf°_{298.15} = -222.0 ± 2 kcal/mol
 S°_{298.15} = 28.91 ± 0.3 gibbs/mol
 Td = 944°K

Heat of Formation.

The enthalpy change for the reaction $\text{FeSO}_4(c) = \text{FeSO}_4(110 \text{ H}_2\text{O})$ was determined to be -14.9 kcal/mol by R. de Forcrand, Comp. rend. 156, 20 (1914). Using $\Delta H_f^{\circ} 298.15 = -235.85$ kcal/mol for $\text{FeSO}_4(110 \text{ H}_2\text{O})$, the heat of formation (298.15°K) for $\text{FeSO}_4(c)$ was calculated as -221 kcal/mol. The value of $\Delta H_f^{\circ} 298.15$ ($\text{FeSO}_4(c)$) was estimated based on $\Delta H_f^{\circ} 298.15 = 235.9$ kcal/mol for $\text{FeSO}_4(200 \text{ H}_2\text{O})$ which was derived from the enthalpy change for the reaction $\text{FeCl}_2(200 \text{ H}_2\text{O}) + \text{H}_2\text{SO}_4(200 \text{ H}_2\text{O}) = \text{FeSO}_4(200 \text{ H}_2\text{O}) + 2\text{HCl}(100 \text{ H}_2\text{O})$ measured by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882-1886. See the $\text{Fe}(\text{OH})_2(c)$ table for details.

The decomposition pressures of $\text{FeSO}_4(c)$ at different temperatures were investigated by J. D'Ans and E. Oreulich. Using their reported partial pressures for $\text{SO}_3(g)$ and $\text{SO}_2(g)$, the enthalpy change for the reaction $2 \text{FeSO}_4(c) = \text{Fe}_2\text{O}_3(c) + \text{SO}_3(g) + \text{SO}_2(g)$ was evaluated by both the second and third law methods. The results obtained are presented in the following table.

Investigator	Temperature, °K	Second Law Value	Third Law Value	ΔHf° _{298.15} kcal/mol
1. J. D'Ans (1905)	753.15 - 908.15	83.2 ± 4.6	82.7 ± 1.1	-222.7
2. E. Oreulich (1927)	887.15 - 971.15	84.8 ± 8.8	80.1 ± 1.4	-221.5
3. B. Neumann and O. Heintke (1937)	833.15 - 862.15	72.4 ± 5.4	75.3 ± 0.5	-219.1

1. J. D'Ans, Dissertation, Darmstadt, 1905. Data quoted by B. Neumann and O. Heintke, loc. cit.
2. E. Oreulich, Z. anorg. Chem. 168, 197 (1927). Only the last seven high temperature points were adopted for evaluation.
3. B. Neumann and O. Heintke, Z. Elektrochem. 43, 246 (1937), based on the last 18 high temperature points adopted.

The decomposition pressures assumed for the same reaction have been determined by B. Neumann and O. Heintke. From their data the partial pressures for $\text{SO}_3(g)$ and $\text{SO}_2(g)$ were evaluated. Using the derived $\text{SO}_3(g)$ and $\text{SO}_2(g)$ partial pressures, the corresponding enthalpy changes for the reaction were calculated by both the second and third law methods. The results obtained are also listed in the same table.

The value of $\Delta H_f^{\circ} 298.15$ for $\text{FeSO}_4(c)$ is selected as -222 ± 2 kcal/mol.

Heat Capacity and Entropy.

The low temperature heat capacities, 53.0-294.9°K, were determined by O. E. Moore and K. K. Kelley, J. Am. Chem. Soc., 64, 2949 (1942). Based on $S^{\circ}_{50.12} = 2.10$ eu, the value of $S^{\circ}_{298.15}$ ($\text{FeSO}_4(c)$) was reported to be 25.71 ± 0.2 eu. Using the free energy functions for $\text{FeSO}_4(c)$ based on this $S^{\circ}_{298.15}$ value, to evaluate the vapor pressure data for Reaction (1), the second and third law values of ΔH_f° were derived as 72.35 ± 7.60 and 86.51 ± 1.26 kcal/mol, respectively. Since the report by Moore and Kelley, loc. cit., did not mention the magnetic entropy contribution, an attempt was made to add 3.20 (= $R \ln 5$) eu to $S^{\circ}_{298.15}$ ($\text{FeSO}_4(c)$) and re-evaluate the decomposition pressure data. The results obtained were better than before (see the paragraph on "Heat of Formation," for details). Therefore the value, $S^{\circ}_{298.15} = 25.71 + 3.2 = 28.91$ eu for $\text{FeSO}_4(c)$, was adopted. The heat capacities above 294.9°K were estimated by comparison with those for $\text{MnSO}_4(c)$. The high temperature heat capacities, 870.3-1082.3°K, were determined by J. C. Southard and C. H. Shomate, J. Am. Chem. Soc. 64, 1770 (1942). The two sets of data were joined smoothly at 298.15°K by use of Shomate-function plot.

Temperature of Decomposition.

Td is the temperature at which the vapor pressure of the gaseous decomposition products equals one atmosphere, which was obtained by graphical interpolation of the decomposition pressure data on $\text{FeSO}_4(c)$, reported by E. Oreulich, loc. cit.

Heat of Formation.

The chemical equilibrium of the interaction of Fe(c) and I(g) has been studied by a transpiration method by W. E. Zeugs and N. W. Gregory, J. Phys. Chem. **70**, 490 (1966). Using the reported equilibrium constants in the temperature range from 591 to 751°K, the enthalpy change ($\Delta H_{298.15}^\circ$) of the reaction $2\text{Fe(c)} + 4 \text{I(g)} = \text{Fe}_2\text{I}_4\text{(g)}$ was evaluated by both the second and third law method to be -85.3 and -103.76 kcal/mol, respectively. The corresponding values of the heat of formation ($\Delta H_{298.15}^\circ$) for $\text{Fe}_2\text{I}_4\text{(g)}$ were calculated as +16.9 and -1.6 kcal/mol.

Mass spectrometric and Knudsen effusion techniques have been used to study the vaporization of $\text{FeI}_2\text{(c)}$ by R. C. Schoonmaker, A. H. Friedman and R. P. Porter, J. Chem. Phys. **31**, 1568 (1959). Using the reported vapor pressure, $P = 1.21 \times 10^{-6}$ atm. at 714°K for $\text{Fe}_2\text{I}_4\text{(g)}$, the enthalpy change ($\Delta H_{298.15}^\circ$) for the reaction $2 \text{FeI}_2\text{(c)} = \text{Fe}_2\text{I}_4\text{(g)}$ was evaluated by the third law method as 52.8 kcal/mol, yielding $\Delta H_{298.15}^\circ = 2.8 \text{ kcal/mol}$ for $\text{Fe}_2\text{I}_4\text{(g)}$. The adopted value of $\Delta H_{298.15}^\circ$ for $\text{Fe}_2\text{I}_4\text{(g)}$ is $2.0 \pm 5 \text{ kcal/mol}$.

Heat Capacity and Entropy.

The molecular structure was assumed to be the same as that assumed for $\text{FeBr}_4\text{(g)}$. The Fe-I bond distance was estimated from that in $\text{FeI}_2\text{(g)}$ molecule. Four vibrational frequencies (ν_i), i.e. $i = 2, 4, 5$ and 6, were estimated by comparison with those for $\text{K}_2\text{I}_2\text{(g)}$, calculated by J. Berkowitz, J. Chem. Phys. **32**, 1519 (1960). The other frequency values were estimated from those for $\text{FeI}_2\text{(g)}$. The electronic levels and quantum weights were estimated from those for $\text{FeI}_2\text{(g)}$. The three principal moments of inertia are: $I_A = 1.2442 \times 10^{-5}$, $I_B = 7.7996 \times 10^{-37}$ and $I_C = 9.0439 \times 10^{-37} \text{ g cm}^2$.

Fe₂O₃

HEMATITE (Fe₂O₃) (CRYSTAL)

MOL. WT. = 159.6922

ΔH_f^o 0 = -195.8 ± 0.3 kcal. mole⁻¹
 ΔH_f^o 298.15 = -197.3 ± 0.3 kcal. mole⁻¹
 S_{298.15} = 20.889 cal. deg.⁻¹ mole⁻¹
 T_d = 1735°K.

Heat of Formation.

The chemical equilibria for the reaction 4Fe₃O₄(c) + O₂(g) = 6Fe₂O₃(c) have been studied by several investigators. From the reported data the corresponding values of ΔH_f^o 298.15 and ΔH_f^o 298.15 (Fe₂O₃, c) were evaluated. The results obtained are given as follows.

Investigator	Temperature, °K.	Second Law Value	Third Law Value	ΔH _f ^o 298.15 ^a kcal. mole ⁻¹
Tretyskov and Khomyakov ¹	1373-1728	-106.32 ± 0.19	-111.05	-197.11
Schmahl ²	1583-1683	-123.95 ± 1.37	-112.94	-197.42
Smitten ³	1373-1673	-117.68 ± 0.38	-114.25	-197.64
Darkey and Gurry ⁴	1725	-110.29	—	-196.98

^aCalculation based on the third law values for ΔH_f^o 298.15.

1 Y.D. Tretyskov and K. O. Khomyakov, Russ. J. Inorg. Chem. **7**, 628 (1962).

2 N. G. Schmahl, Z. Elektrochem. **47**, 821 (1941).

3 J. Smitten, J. Am. Chem. Soc. **73**, 4877 (1951).

4 L. S. Darkey and R. W. Gurry, J. Am. Chem. Soc. **68**, 798 (1946).

ΔH_f^o 298.15 was calculated based on ΔH_f^o 1725 = -54.5 kcal. mole⁻¹.

The value of ΔH_f^o 298.15 adopted for Fe₂O₃(c) is the weighted average of the ΔH_f^o 298.15 values listed in the above table.

Heat Capacity and Entropy.

The low temperature (5.58-345.42°K.) heat capacities were determined by F. Gronvold and E. F. Westrum, Jr., J. Am. Chem. Soc. **81**, 1780 (1959). The high temperature (298-1750°K.) C_p values were obtained from J. P. Coughlin, E. G. King and K. R. Bonnickson, J. Am. Chem. Soc. **73**, 3691 (1951). The two sets of data were plotted and joined smoothly at 298°K. The C_p values above 1750°K. were obtained by graphical extrapolation. The heat capacities of Fe₂O₃(c) have also been reported by G. G. Brown and C. C. Furnas, Trans. Am. Inst. Chem. Eng. **18**, 309 (1926), 0-650°K., and G. S. Parks and K. K. Kelley, J. Phys. Chem. **30**, 47 (1926), 68-289°K. S_{298.15} for Fe₂O₃(c) was derived from the smoothed C_p data, based on S₅ = 0.0003 e.u. J. P. Coughlin, E. G. King and K. R. Bonnickson, loc. cit. measured the heat-content for hematite and found two anomalies, presumably of magnetic nature, at about 950 and 1050°K., respectively. Both appear to involve maxima in the heat-capacity curves rather than isothermal heats of transformation. The complex magnetic properties at low temperatures were discussed by F. Gronvold and E. F. Westrum, Jr., loc. cit. No heat capacity anomaly was observed at the magnetic transition about 250°K. The Curie points of the antiferromagnetic α-Fe₂O₃ were reported by A. Aharoni, E. H. Frei and M. Schieber, Phys. Rev. **127**, 439 (1962) and J. Liekeza and A. C. D. Chaklader, Phys. Rev. Letters, **13**, 866 (1965).

Temperature of Decomposition.

T_d is the temperature at which ΔH_f^o = 0 for the reaction 6Fe₂O₃(c) = 4Fe₃O₄(c) + O₂(g). In other words, Fe₂O₃(c) decomposes into Fe₃O₄(c) and O₂(g) at 1735°K.

$\Delta H_f^\circ = \text{Unknown}$
 $\Delta H_f^\circ_{298.15} = -617.35 \pm 0.40 \text{ kcal/mol}$
 $S^\circ_{298.15} = [73.5 \pm 2] \text{ gibbs/mol}$
 $T_d = 1451^\circ\text{K}$

Heat of Formation.

The enthalpy change ($\Delta H_f^\circ_{298.15}$) for the chemical reaction $\text{Fe}_2\text{O}_3(\text{c}) + 3\text{H}_2\text{SO}_4(14.855 \text{ H}_2\text{O}) = \text{Fe}_2(\text{SO}_4)_3(\text{c}) + 3\text{H}_2\text{O}(1)$ was measured to be $8.54 \pm 0.18 \text{ kcal/mol}$ by solution calorimetry by R. Barany and L. H. Idemi, U. S. Bur. Mines RI 6887, 1955. Using $\Delta H_f^\circ_{298.15} = -211.178 \text{ kcal/mol}$ for $\text{H}_2\text{SO}_4(14.855 \text{ H}_2\text{O})$ and -68.315 kcal/mol for $\text{H}_2\text{O}(1)$, obtained from "Selected Values of Chemical Thermodynamic Properties," NBS Technical Note 270-1, by D. D. Wagman and coworkers, National Bureau of Standards, 1965, and -197.3 kcal/mol for $\text{Fe}_2\text{O}_3(\text{c})$, the heat of formation ($\Delta H_f^\circ_{298.15}$) for $\text{Fe}_2(\text{SO}_4)_3(\text{c})$ was evaluated as $-617.35 \pm 0.40 \text{ kcal/mol}$ which was adopted here.

The equilibrium pressures for the decomposition of $\text{Fe}_2(\text{SO}_4)_3(\text{c})$ have been determined by several investigators at different temperatures. The chemical reactions involved are: (1) $\text{Fe}_2(\text{SO}_4)_3(\text{c}) = \text{Fe}_2\text{O}_3(\text{c}) + 3\text{SO}_3(\text{g})$ and (2) $\text{SO}_3(\text{g}) = \text{SO}_2(\text{g}) + 0.5 \text{ O}_2(\text{g})$. However, the measured pressure of the chemical equilibrium is the total pressure of three partial pressures, namely, P_{SO_3} , P_{SO_2} , and P_{O_2} . In order to calculate the enthalpy change of Reaction (1), the partial pressures of $\text{SO}_3(\text{g})$ were evaluated from the total vapor pressure data at each temperature. Based on the derived values for P_{SO_3} , the $\Delta H_f^\circ_{298.15}$ value for Reaction (1) was calculated by both the second and third law methods. The results obtained are presented in the following table. The $\Delta H_f^\circ_{298.15}$ ($\text{Fe}_2(\text{SO}_4)_3$, c) values were derived, using the third law $\Delta H_f^\circ_{298.15}$. These determinations were not given any weight.

Investigator	Temperature, °K	Second Law Value	Third Law Value	Drift	$\Delta H_f^\circ_{298.15}$ kcal/mol
1. Keppeler and D'Ana (1908)	753.15 - 1013.15	136.8 ± 0.5	139.9 ± 0.5	3.4 ± 0.6	-621.0

6. N. A. Warner and T. R. Ingraham, Can. J. Chem. 38, 2196 (1960).

The decomposition pressures of $\text{Fe}_2(\text{SO}_4)_3(\text{c})$ have also been investigated by: M. Ordnzweig, Ph. D. dissertation, Darmstadt, Germany, 1913, 793-994°K; R. P. Blanka, Ph. D. dissertation, University of Melbourne, Australia, 1961, 845 - 978°K; and T. R. Ingraham, Internal Rept. EMT-53-17, Department of Mines and Technical Surveys, Ottawa, Canada, 1963, 856-995°K. These data together with some of the data mentioned previously were critically reviewed by H. H. Kellogg, Trans. AIME, 230, 1622 (1964).

Heat Capacity and Entropy.

The heat capacities were estimated by comparison with those for $\text{FeSO}_4(\text{c})$, assuming their average specific heats, Gibbs/g, to be the same. The value of $S^\circ_{298.15}$ was estimated so that the second and third law $\Delta H_f^\circ_{298.15}$ values, derived from decomposition pressure data, are in reasonable agreement.

Temperature of Decomposition.

T_d is the temperature at which the total pressure of the gaseous products equals one atmosphere, which was obtained by graphical extrapolation of the decomposition pressure data measured by Warner and Ingraham, loc. cit.

Heat of Formation.

The equilibrium constants for the following four reactions, i.e. (1) $3\text{Fe(c)} + 4\text{H}_2\text{O(g)} = \text{Fe}_3\text{O}_4(\text{c}) + 4\text{H}_2(\text{g})$; (2) $\text{Fe}_3\text{O}_4(\text{c}) + \text{H}_2(\text{g}) = 3\text{FeO(c)} + \text{CO(g)}$; (3) $\text{Fe}_3\text{O}_4(\text{c}) + \text{CO(g)} = 3\text{FeO(c)} + \text{CO}_2(\text{g})$; and (4) $2\text{Fe}_3\text{O}_4(\text{c}) = 6\text{FeO(c)} + \text{O}_2(\text{g})$, have been studied by several investigators. Using their reported equilibrium data, the corresponding enthalpy changes (ΔH_f° 298.15) were evaluated by both the second and third law methods. Based on the third law value for ΔH_f° 298.15, the respective ΔH_f° 298.15 values for $\text{Fe}_3\text{O}_4(\text{c})$ were also derived. The results obtained are presented as follows.

Investigator	Reaction	Temperature, °K.	Second Law Value	Third Law Value	ΔH_f° 298.15 kcal. mole ⁻¹
Pricker, et al. ¹	(1)	633.2-823.2	-29.68 ± 1.30	-36.91	-268.10
Eastman ²	(2)	873.2-1273.2	22.41 ± 0.09	19.29	-266.01
Eastman and Evans ³	(2)	973.2-1273.2	21.56 ± 0.07	18.54	-267.26
Emmett and Schultz ⁴	(2)	973.2-1073.2	—	19.18	-267.30
Eastman ²	(3)	873.2-1273.2	11.87 ± 0.03	9.38	-267.93
Eastman and Evans ³	(3)	973.2-1273.2	11.63 ± 0.03	9.38	-267.94
Salmon ⁵	(4)	1473.2-1673.2	—	153.73	-267.79

1 R. Pricker, K. Walter and W. Lehnert, Z. Elektrochem. 47, 487 (1941). The two ΔH_f° 298.15 values listed are the average values of three separate results derived from three sets of experimental data.

2 E. D. Eastman, J. Am. Chem. Soc. 44, 975 (1922).

3 E. D. Eastman and R. M. Evans, J. Am. Chem. Soc. 46, 888 (1924).

4 P. H. Emmett and J. P. Schultz, J. Am. Chem. Soc. 52, 4268 (1930).

5 O. N. Salmon, J. Phys. Chem. 65, 550 (1961).

The enthalpy change of the reaction $\text{Fe}_3\text{O}_4(\text{c}) + 0.8215 \text{ Fe(c)} + 0.5787 \text{ O}_2(\text{g}) = 0.5895 \text{ Fe}_3\text{O}_4(\text{c})$ has been determined by O. L. Humphrey, E. O. King and K. K. Kelley, U. S. Bur. Mines RI 4870 (1952). Based on ΔH_f° 298.15 = -93.45 kcal. mole⁻¹ (average of two separate values derived from two experimental determinations) and ΔH_f° 298.15 (Wüster, c) = -63.64 kcal. mole⁻¹, the value of ΔH_f° 298.15 (Fe_3O_4 , c) was calculated as -266.5 kcal. mole⁻¹. The enthalpy change, ΔH_f° 298.15 = 4.33 kcal. mole⁻¹, for the reaction $3\text{Fe(c)} + 4\text{CO}_2(\text{g}) = \text{Fe}_3\text{O}_4(\text{c}) + 4\text{CO(g)}$ was reported by L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 68, 798 (1946). The corresponding ΔH_f° 298.15 (Fe_3O_4 , c) was evaluated as -266.22 kcal. mole⁻¹. The adopted value of ΔH_f° 298.15 for $\text{Fe}_3\text{O}_4(\text{c})$ is selected as -267.9 ± 0.2 kcal. mole⁻¹.

Heat Capacity and Entropy.

The low temperature (60.5-299.7°K.) heat capacities were reported by R. W. Millar, J. Am. Chem. Soc. 51, 215 (1929). The high temperature (298-1800°K.) heat capacities were obtained from J. P. Coughlin, E. O. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3891 (1951). These two sets of data were plotted and joined smoothly at 298°K. The C_p values above 1800°K. were obtained by graphical extrapolation. Heat capacities (90-295°K.) for $\text{Fe}_3\text{O}_4(\text{c})$ were also reported by O. S. Parks and K. K. Kelley, J. Phys. Chem. 50, 47 (1926). $S^\circ_{298.15}$ (Fe_3O_4 , c) was derived from the smoothed C_p data mentioned previously, using $S^\circ_{4.7} = 0.969 \text{ e.u.}$ J. P. Coughlin, E. O. King and K. R. Bonnickson, loc. cit. measured the heat-content for magnetite and found a magnetic anomaly around 880°K., corresponding to a maximum in heat capacity. A maximum heat capacity of 37.1 cal. deg.⁻¹ mole⁻¹ at 114.15°K. was also reported by R. W. Millar, loc. cit.

Melting Data.

T_m and ΔH_m° were obtained from L. S. Darken and R. W. Gurry, loc. cit.

Heat of Formation

The heat of formation was calculated from $D_0^\circ(\text{H}_2) = 36113.0 \pm 0.3 \text{ cm.}^{-1}$, reported by G. Herzberg and A. Monfilla, J. of Molecular Spectroscopy 5, 482 (1960). This value was measured more precisely than the value $D_0^\circ(\text{H}_2) = 36116 \pm 6 \text{ cm.}^{-1}$ by H. Boulier, Z. Phys. Chem. B23, 315 (1935).

Heat Capacity and Entropy

Electronic levels taken from C. E. Moore, Natl. Bur. Standards (U. S.) Circ. 467 (1949).

(IDEAL GAS)

PROTON (H⁺)

ΔH_{f,0}^o = 365.236 ± 0.01 kcal/mol
ΔH_{f,298.15}^o = 367.186 ± 0.01 kcal/mol

S_{298.15}^o = 26.012 gibbs/mol

Heat of Formation

The heat of formation was calculated from the equation H(g) → H⁺(g) + e⁻ with the JANAF auxiliary data for H(g), using an ionization potential = 13.598 eV (313.605 kcal/mol) for H(g) obtained from C. W. Beckett, National Bureau of Standards Report 8628, Jan. 1, 1965.

Heat Capacity and Entropy

Calculated by assuming the proton to be an ideal monatomic gas. The enthalpy between 298° and 0°K is 1.481 kcal/mol as for all unexcited monatomic gases.

June 30, 1966

H⁺

Hydrogen Uninegative Ion (H⁻)

S°_{298.15} = 26.015 cal. deg.⁻¹ mole⁻¹
ΔH°_f 0 = 34.2 ± 0.5 kcal. mole⁻¹
ΔH°_f 298.15 = 33.2 ± 0.5 kcal. mole⁻¹

Electronic Levels and Quantum Weight

E ₁ cm. ⁻¹	E ₁
0	1

Heat of Formation.

The heat of formation was calculated from the equation: H(g) + e⁻ → H⁻(g) with the JANAF auxiliary value for H(g) (this supplement), using an I.P. = 6.083098 X 10³ cm.⁻¹ (.754 e.v. or 17.39 kcal/mole) for H⁻(g) obtained from C. L. Pekeris, Phys. Rev. 125, 1470 (1962). The I.P. value for H⁻(g) reported by C. W. Scherr and R. E. Knight, Rev. Mod. Phys. 35, 436 (1963) is in agreement with the value of Pekeris.

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, U. S. National Bureau of Standards Circular 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Helium. The electronic levels above 1 X 10⁵ cm.⁻¹ were omitted because their contribution is negligible below 6000°K. The H⁻ H₂₉₈ value at 0°K. is -1.481 kcal/mole.

Mercury Monohydride (HgH)

(Ideal Gas)

MOL. WT. = 201.618

Ground State Configuration [$^2\Sigma^+$]
 $\Delta H_f^0 = 58 \pm 4$ kcal. mole⁻¹
 $S_{298.15}^0 = [52.486]$ cal. deg.⁻¹ mole⁻¹
 $\Delta H_f^0 = 298.15 = 57 \pm 4$ kcal. mole⁻¹

Electronic Levels and Multiplicities

$$\frac{\epsilon_1 \text{ cm.}^{-1}}{0} \quad \frac{g_1}{[2]}$$

$$\omega_e = 1387 \text{ cm.}^{-1}$$

$$\omega_e x_e = 83.01 \text{ cm.}^{-1}$$

$$\sigma = 1$$

$$B_e = 5.549 \text{ cm.}^{-1}$$

$$\alpha_e = 0.312 \text{ cm.}^{-1}$$

$$r_e = 1.74 \text{ \AA}$$

Heat of Formation.

The heat of formation was calculated from D_0 , 8.671 kcal. mole⁻¹, taken from G. Herzberg, "Spectra of Diatomic Molecules," 2nd Edition, D. Van Nostrand Company, Inc., New York (1950).

Heat Capacity and Entropy.

Molecular constants were taken from G. Herzberg, loc. cit.

September 30, 1961

$$\Delta H_{f0}^{\circ} = 6.82 \pm 0.05 \text{ kcal. mole}^{-1}$$

$$\Delta H_{f298}^{\circ} = 6.30 \text{ kcal. mole}^{-1}$$

$$S_{298}^{\circ} = 49.351$$

$$\text{Ground State} = 1 \sum$$

$$\omega_e = 2309.06 \text{ cm}^{-1}$$

$$\omega_e x_e = 39.73 \text{ cm}^{-1}$$

$$B_e = 8.512 \text{ cm}^{-1}$$

$$\alpha_e = 0.1715 \text{ cm}^{-1}$$

$$G = 1$$

Thermodynamic Functions.

Molecular constants are from M. Cowan and W. Gordy [Phys. Rev. 104, 551 (1956)] and D. R. J. Boyd and H. W. Thompson [Spectrochim. Acta 5, 308 (1952)]. The calculated functions are in reasonable agreement with the compilation of K. K. Kelley [U. S. Bur. Mine Bull. 504 (1960)].

Heat of Formation.

Using the calculated functions derived above and functions for H₂(g) and I₂(g) given in the JANAP tables, equilibrium data from the literature were used to calculate ΔH_{f298}° for the reaction

$$\Delta H_{f298}^{\circ} \text{ kcal. mole}^{-1}$$

$$\begin{aligned} &\text{Taylor and Crist}^1 \quad (667^\circ \text{ to } 764^\circ \text{K}) \\ &\text{Bodenstein}^2 \quad (556^\circ \text{ to } 781^\circ \text{K}) \\ &\text{Bright and Hagerly}^3 \quad (696^\circ \text{ and } 779^\circ \text{K}) \\ &\text{Rittenberg and Urey}^4 \quad (671^\circ \text{ and } 741^\circ \text{K}) \end{aligned}$$

The data of Taylor and Crist are the most concordant and are given the most weight. Converting to the solid state of iodine, which has been adopted as a JANAP reference state gives the standard heat of formation of hydrogen iodide.

(CRYSTAL)

POTASSIUM HYDRIDE (KH)

HK

 ΔH°_f O = Unknown ΔH°_f 298.15 = -13.819 ± 0.011 kcal. mole⁻¹ $S^\circ_{298.15}$ = [12] cal. deg.⁻¹ mole⁻¹ T_d = [590]*K.

Heat of Formation.

The value of ΔH°_f 298.15 was taken from S. R. Gunn and L. G. Green, J. Am. Chem. Soc. **80**, 4782 (1958). The corresponding value reported by C. E. Measer, L. O. Pasolun and C. E. Thalmer, J. Am. Chem. Soc. **77**, 4524 (1955) was -15.16 ± 0.6 kcal. mole⁻¹. In this paper the results of the previous investigations were also reviewed.

Heat Capacity and Entropy.

C_p and $S^\circ_{298.15}$ were estimated by comparison with those for NaH(c) and LiH(c).

Temperature of Decomposition.

T_d was assumed to be the temperature at which the value of ΔF°_f changes from negative to positive.

$\Delta H_f^0 = -100.7 \pm 0.1$ kcal. mole⁻¹
 $\Delta H_f^{298.15} = -101.5 \pm 0.1$ kcal. mole⁻¹
 $\Delta H_f^0 = 1.515$ kcal. mole⁻¹
 $\Delta H_f^{298} = 2.240$ kcal. mole⁻¹
 $\Delta H_g^{298.15}$ (to monomer) = [46.1] kcal. mole⁻¹
 $\Delta H_g^{298.15}$ (to dimer) = [45.6] kcal. mole⁻¹

Heat of Formation.

The standard enthalpy of formation, ΔH_f^{298} (KOH, c) = -101.5 ± 0.1 kcal. mole⁻¹, was calculated from the heat of solution of KOH(c), the heat of hydrolysis of potassium metal and the appropriate auxiliary data.

N. A. Peshetnikov¹ has measured the heat of solution KOH(c) → KOH(650 H₂O) as -13.665 ± 0.009 kcal. mole⁻¹ at 298.15°K. in the solution calorimeter. Using the auxiliary heat of dilution reported by V. B. Parker², the selected heat of solution of KOH(c) at infinite dilution is -13.770 kcal. mole⁻¹. The heat of solution KOH(c) → KOH(25 H₂O) has also been measured as -13.80 ± 0.10 kcal. mole⁻¹ in the solution calorimeter by W. E. Hatton, D. L. Hildenbrand, G. C. Sinke and D. R. Stull³. Both results are in good agreement.

The heat of hydrolysis of potassium metal, ΔH_f^{298} , has been measured in the solution calorimeter by the following investigators.

Source	Number of Moles of H ₂ O	ΔH_f^{298} kcal. mole ⁻¹	ΔH_f^{298} (KOH(c)) kcal. mole ⁻¹	ΔH_f^{298} (KOH, c) kcal. mole ⁻¹
Gunn et al. ⁴	1000	-46.877 ± 0.01	-115.281	-101.511
Messer et al. ⁵	∞	-47.02 ± 0.15	-115.345	-101.565
Ketchen et al. ⁶	∞	-46.894 ± 0.24	-115.209	-101.439

The values of ΔH_f^{298} (KOH(c)) were calculated from the heats of reaction, ΔH_r^{298} , using ΔH_f^{298} (H₂O, l) = -68.315 kcal. mole⁻¹. Combination of the selected heat of solution of KOH(c) at infinite dilution with the heat of formation of KOH(c) gives the heat of formation of KOH(c) in the last column of the table. A weighted average of these three measurements was taken for the selected heat of formation of KOH(c).

The earlier investigations have been reviewed by F. R. Bichowsky and F. D. Rossini⁸ and C. E. Messer et al.⁵, and these earlier reported data are not adopted in the tabulation.

Heat Capacity and Entropy.

The low temperature heat capacities of KOH(c) from 15° to 340°K. have been measured by W. E. Hatton et al.³ who have also observed a sharp peak in the heat capacity curve in the temperature range from 210° to 230°K. These values of C_p were adopted in the calculation. W. D. Powers and G. C. Blalock⁹ have measured the high temperature enthalpy changes of the solid KOH in the α and β phases by the drop method. Their enthalpy data are scattered and not precise enough to accurately define the heat capacities in the α phase. Therefore, the selected heat capacities between 340° and 522°K. were estimated from a graphical extrapolation of the low temperature heat capacity curve, and the tabulated $H^0-H_{298}^{298}$ functions are in agreement with their enthalpy measurements within the experimental uncertainty. The heat capacities of KOH(c) in the β phase were obtained from Powers and Blalock⁹.

The entropy ($S_{298}^{298} = 18.95$ cal. deg.⁻¹ mole⁻¹) was taken from Hatton et al.³, based on an extrapolation of $S_{15}^{298} = 0.054$ cal. deg.⁻¹ mole⁻¹.

Transition and Melting Data.

Hatton et al.³ have found a lambda transition at 227.4°K. in the heat capacity measurement. The adopted heat of α-β transition at 522°K. and heat of melting at 673°K. were obtained from Powers and Blalock⁹. P. S. Seward and K. E. Martin¹⁰ found $\Delta H_m^{298} = 1.83$ kcal. mole⁻¹ at 693°K. In phase diagram studies of the system KOH-K₂CO₃.

Heat of Sublimation.

See KOH(g) table for details.

$S_{298.15}^o = 23.518$ cal. deg.⁻¹ mole⁻¹
 $T_m = 673^\circ K.$
 T_b (monomeric gas) = 1600°K.
 $\Delta H_f^o = 2.240$ kcal. mole⁻¹
 ΔH_v^o (to monomer) = 32.0 kcal. mole⁻¹

Heat of Formation.

The heat of formation of KOH(l) at 298°K. was obtained from that of the crystal by adding ΔH_m^o and the difference between H_{298}^o and H_{298}^o for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase, $C_p = 19.86$ cal. deg.⁻¹ mole⁻¹, was obtained from the enthalpy measurements in the drop calorimeter by W. D. Powers and O. C. Blalock, ORNL-1653, Oak Ridge Nat'l. Lab., Jan. 1954. The constant C_p was extrapolated below the melting point and up to 2500°K.

The entropy, $S_{298.15}^o = 23.51$ cal. deg.⁻¹ mole⁻¹, was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See KOH(c) table for details.

Vaporization Data.

The boiling point 1600°K. was calculated as the temperature at which the free energies of formation (ΔF_f^o) for both KOH(l) and KOH(g) are equal. The difference in the heats of formation (ΔH_f^o) of KOH(l) and KOH(g) at the boiling point is the heat of vaporization. If $K_2(OH)_2(g)$ is also considered as a minor component in the vapor mixture (approximately 2% of total vapor pressure at the boiling point) the calculated boiling point is unchanged as 1600°K. (see KOH(c) table for details).

H. von Wertenberg and P. Albrecht, Z. Elektrochem. 27, 182 (1921), have studied the vapor pressures of liquid KOH and reported the boiling point as 1597°K.

Heat of Formation.

R. P. Porter and R. C. Schoonmaker, J. Phys. Chem. 62, 234 and 466 (1958), have investigated the potassium hydroxide vapor by the mass-spectrometric method and found that the KOH vaporizes mainly as gaseous dimer in the temperature range from 573° to 723°K. Later, Schoonmaker and Porter, J. Chem. Phys. 31, 830 (1959), found the activity of molten alkali hydroxide had been reduced in the presence of MgO in their sample container. Using the reported partial pressures of KOH(g) and $K_2(OH)_2(g)$ at 641° and 666°K. and JANAF free energy functions, the third law calculations give $\Delta H_{298}^\circ = -45.4 \pm 5 \text{ kcal. mole}^{-1}$ for $2KOH(g) \rightarrow K_2(OH)_2(g)$, and $\Delta H_{298}^\circ = 45.41 \pm 3.5 \text{ kcal. mole}^{-1}$ for $KOH(g) \rightarrow KOH(c)$, and $\Delta H_{298}^\circ = 45.6 \pm 5 \text{ kcal. mole}^{-1}$ for $2KOH(c) \rightarrow K_2(OH)_2(g)$. The uncertainties given were derived by assuming I_B to be good to a factor of 5 as stated by the authors and including an extra factor of 2 as a possible error in activity. To this was added an estimate of the uncertainty due to functions used. In order to have good agreement between the calculated total pressures of monomeric and dimeric KOH(g) and the observed vapor pressures measured by H. von Wartenberg and P. Albrecht, Z. Elektrochem. 27, 182 (1921), the heat of sublimation to monomeric gas was adjusted to $\Delta H_{298}^\circ = 46.08 \text{ kcal. mole}^{-1}$. (The heat of sublimation to dimeric gas was unchanged as $\Delta H_{298}^\circ = 45.64 \text{ kcal. mole}^{-1}$). The calculated boiling point is 1600°K. which is in good agreement with 1597 $\pm 10^\circ$ K. reported by Wartenberg and Albrecht. The heats of formation were calculated from the selected heats of sublimation as $\Delta H_{298}^\circ(KOH, g) = -55.4$ and $\Delta H_{298}^\circ(K_2(OH)_2, g) = -157.4 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The bond distance K-O was estimated by adding the bond length difference (0.04 Å) between H-OH(g) and H-F(g) to the bond distance K-F(g) (2.1746 Å) which has been accurately measured by R. K. Ritchie and H. Lew, Can. J. Phys. 42, 43 (1964). The bond distance O-H was estimated from that in $H_2O(g)$. The bent molecular configuration with the bond angle of 110° has also been proposed by S. H. Bauer, R. M. Diner and R. F. Porter, J. Chem. Phys. 23, 931 (1956), but a linear model has also been suggested by R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. 31, 830 (1959). The bent model has been adopted in the tabulation. The three principal moments of inertia are: $I_A = [0.1256] \times 10^{-39}$, $I_B = [9.8070] \times 10^{-39}$ and $I_C = [9.9326] \times 10^{-39} \text{ g. cm.}^2$.

The K-O stretching frequency (408 cm.^{-1}) was obtained from L. H. Spinar and J. L. Margrave, Spectrochim. Acta 12, 244 (1957) in the infrared spectroscopic studies. The O-H stretching and the bending frequencies were estimated by comparison with H-OH, D-OH and T-OH which indicate rapid convergence to a constant as a heavier atom is attached.

L. Brewer and D. P. Mastic, J. Am. Chem. Soc. 73, 2045 (1951), have calculated theoretically the bond distances of gaseous alkali oxides ($I_1 O = 1.52 \text{ \AA}$, $Na O = 1.94 \text{ \AA}$ and $K O = 2.27 \text{ \AA}$) which have been quoted by Bauer, Diner and Porter, loc. cit., and many other authors.

Heat of Formation

The heats of solution of Li(c) and LiH(c) in water have been measured by Cuntz (1) and Hoers (2) using an open Dewar flask calorimeter and by Messer (3) and Gunn (4) using closed bomb calorimetry. Based on the reported values of the enthalpy changes (ΔH°) for the reaction (A) $\text{Li(c)} + \text{H}_2\text{O(l)} \rightarrow \text{LiOH(aq)} + 1/2\text{H}_2\text{(g)}$, and (B) $\text{LiH(c)} + \text{H}_2\text{O(l)} \rightarrow \text{LiOH(aq)} + \text{H}_2\text{(g)}$, the corresponding ΔH°_{298} for LiH(c) are calculated. The results are presented in the table below.

The decomposition pressures of LiH(c) have been determined by Hurd (5), at temperatures 782 - 926°K. By use of the second and third law methods, the enthalpy changes for the decomposition reaction (C) $\text{LiH(c)} \rightarrow \text{Li(c)} + 1/2\text{H}_2\text{(g)}$ are evaluated as 21.87 ± 0.3 and 22.34 kcal/mol, respectively. Based on the third law ΔH°_{298} and $\Delta H^{\circ}_{298}(\text{Li, l}) \pm 0.569$ kcal/mol, we derive the value $\Delta H^{\circ}_{298}(\text{LiH, c}) = -21.77 \pm 0.2$ kcal/mol, which is in good agreement with the values obtained by calorimetric method. Gunts (1) measured the decomposition pressure at 953°K for the same reaction. The third law ΔH°_{298} and $\Delta H^{\circ}_{298}(\text{LiH, c})$ are evaluated as 21.86 and -21.79 kcal/mol, respectively.

Johnson (6) has determined the standard Gibbs energy of formation (ΔG°) for LiH(c) from emf measurements over the temperature range 875 - 885°K. The cell utilized an Amoco Iron flag over which H_2 was passed as the cathode and a molten Li anode. LiCl, LiBr, and LiI, each saturated with LiH were used as electrolytes. Using the reported emf values at different temperatures (47 data points) for reaction (C), we derive a $\Delta H^{\circ}_{298} = -21.81$ kcal/mol for LiH(c). The $\Delta H^{\circ}_{298}(\text{LiH, c})$ value reported by Gunn (4) is adopted.

Investigator	Reaction A	Reaction B	Reaction C	Drift eu	ΔH°_{298} kcal/mol
1. Cuntz (1896)	-53.2	-31.6	-	-	-21.6
2. Hoers (1920)	-52.7±0.2	-31.1±0.1	21.86	-	-21.29
3. Messer (1955)	-53.10±0.11	-31.76±0.10	-	-	-21.6±0.25
4. Gunn (1958)	-53.14±0.02	-31.48±0.02	-	-	-21.34±0.15
5. Hurd (1935)	-	-	22.34	0.5±0.3	-21.66±0.03
6. Johnson (1966)	-	-	22.38	1.0±0.2	-21.81±0.15

Heat Capacity and Entropy

The low temperature heat capacities are obtained from the data of Kostyukov (7), 3.72 - 295.5°K. The cp data reported by Gunther (8) are consistently lower than the adopted ones in the temperature range 74.0 - 90.5°K but considerably higher at 292.7°K. The high temperature enthalpies have been determined by Fieldhouse (9), 413.2 - 914.3°K, and Vogt (10), 878.15 - 953.15°K. The derived high temperature heat capacities are joined smoothly with the low temperature values and extrapolated smoothly above 953.15°K.

S°_{298} is calculated based on the adopted low temperature heat capacities, using $S^{\circ}_2 = 0.0002$ eu.

Melting Data

The value of T_m has been reported as 953 (1), 961 ± 1 (10, 12), 959.6 (11), and 961.8 ± 0.3 (13). The value reported by Messer (13) is adopted. The heat of melting (ΔH_m°) has been determined as 5.095 ± 0.46 (13) and 5.237 ± 0.040 kcal/mol (14). The first ΔH_m° value was evaluated cryogenically from the lowering of melting point in the systems LiH-Li₂O and LiH-CaH₂. The second value was derived from enthalpy data measured with copper block calorimeter. The adopted ΔH_m° value is derived from the enthalpy data of Vogt (14) using the adopted heat capacities for LiH(c) and LiH(l).

Heat of Sublimation

The value of ΔH°_{298} is calculated as the difference between ΔH°_{298} for LiH(g) and LiH(c).

(IDEAL GAS)

LITHIUM HYDRIDE (LiH)

GFW = 7.94697

Ground State Configuration $1s^2$

$\Delta H_f^\circ = 33.65 \pm 0.01$ kcal/mol

$\Delta H_{298.15}^\circ = 33.61 \pm 0.01$ kcal/mol

$S_{298}^\circ = 40.821$ gibbs/mol

Electronic Levels and Quantum Weights

ϵ_i , cm ⁻¹	g_i
0	1
26513.7	1
30912.0	2
$\omega_e x_e = 23.24$ cm ⁻¹	
$\omega_e = 1406.73$ cm ⁻¹	
$\sigma = 1$	
$\nu_e = 1.595 \text{ } \mu$	
$\nu_e = 0.2137$ cm ⁻¹	

Heat of Formation

R. Velasco, Can. J. Phys. **35**, 1704 (1957), observed the absorption spectra of LiH(g) in the near ultraviolet with high dispersion and absorbing path lengths up to 16 meters. He found a new band system involving the ground state and a $^1\Pi$ excited state. Rotational and vibrational analyses of this system were carried out and the observed breaking off of the rotational structure of the bands was interpreted as due to predissociation by rotation. With this assumption very accurate dissociation limits of the $B^1\Pi$ state were obtained. From these dissociation limits the dissociation energy (D_0) of the ground state of LiH was found to be 2.4288 ± 0.0002 eV. Based on this D_0 value, we adopt $\Delta H_f^\circ = 33.61$ kcal/mol for LiH(g).

W. Kemperer, J. Chem. Phys. **23**, 2452 (1955), observed the infrared spectrum of LiH(g) in emission in the frequency region 1500 to 970 cm⁻¹, using a Perkin-Elmer double-pass monochromator with NaCl optics. Estimating the minimum LiH pressure as 10 mm and assuming the maximum possible Li pressure, he reported $K = 0.005$ (atm) at 1400°K for the reaction $2Li(g) + H_2(g) = 2LiH(g)$. We calculate the corresponding enthalpy change, ΔH_{1400}° , to be -9.63 kcal/mol, employing $\Delta S_{1400}^\circ = -17.407$ eu. Incorporating this ΔH_{1400}° value with $\Delta H_f^\circ = 35.601$ kcal/mol for Li(g), we obtain $\Delta H_{298}^\circ = 33.92$ kcal/mol for LiH(g), which is in good agreement with the adopted value.

A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953, derived the value $D_0(LiH) = 2.5 \pm 0.2$ eV from earlier spectroscopic data.

Heat Capacity and Entropy

The third electronic level and quantum weight are obtained from Velasco, loc. cit. All the other constants are taken from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., and corrected to the average isotopic species. The moment of inertia is 3.7183×10^{-40} g cm².

Dec. 31, 1960; Sept. 30, 1967

S₂₉₈⁰ = 10.225 cal. deg.⁻¹ mole⁻¹
 T_m = 744.3°K.

Heat of Formation.

The standard enthalpy of formation, ΔH_f⁰ 298 (LiOH, c) = -115.84 ± 0.1 kcal. mole⁻¹, was calculated from the heat of solution of lithium hydroxide (c), the heat of hydrolysis of lithium metal and the appropriate auxiliary data. N. A. Peabody⁷ has measured the heat of solution LiOH(c) → LiOH(400 H₂O) as -5.479 ± 0.007 kcal. mole⁻¹ at 298.15°K. by solution calorimetry. Using the auxiliary heat of dilution reported by V. B. Parker⁸, the selected heat of solution of lithium hydroxide (c) at infinite dilution is -5.632 kcal. mole⁻¹.

The heat of hydrolysis of lithium metal, ΔH_f⁰ 298, has been measured in the solution calorimeter by the following investigators.

Source	Number of moles of H ₂ O	ΔH _f ⁰ 298 kcal. mole ⁻¹	ΔH _f ⁰ 298 (LiOH(c)) kcal. mole ⁻¹
Gunn et al. ³	1000	-53.115 ± 0.019	-121.532
Messer et al. ⁴	OO	-53.075 ± 0.20	-121.390
			-115.900
			-115.758

The values of ΔH_f⁰ 298 (LiOH(c)) were calculated from the heats of reaction ΔH_f⁰ 298, using the ΔH_f⁰ 298 (H₂O, l) = -68.315 kcal. mole⁻¹.⁵ Combination of the selected heat of solution of LiOH(c) at infinite dilution with the heat of formation of LiOH(c) gives the heat of formation of LiOH(c) in the last column of the table. A weighted average of these measurements was taken for the adopted heat of formation of lithium hydroxide (c).

The earlier calorimetric investigations have been reviewed by P. R. Bichowsky and F. D. Rossini⁶, and C. E. Messer et al.⁴, and these data are not adopted in the tabulation.

Heat Capacity and Entropy.

The low temperature heat capacities of lithium hydroxide (c) from 15.91° to 302.85°K. have been measured by T. W. Bauer, H. L. Johnston and E. C. Kerr.⁷ The high temperature heat capacities which were determined from the enthalpy measurements in the temperature range from 418° to 878°K. by the drop method have been reported by C. H. Shomate and A. J. Cohen.⁸ The low temperature and the high temperature heat capacities have been joined smoothly by the Shomate method.⁹ The smooth values of heat capacity of LiOH(c) were adopted in the tabulation.

W. D. Powers and G. C. Blalock¹⁰ have also measured the high temperature enthalpy changes of LiOH(c) by the drop method. Their results are in agreement with the tabulated H_m-H₂₉₈ values within the experimental uncertainty.

The entropy (S₂₉₈⁰ = 10.225 cal. deg.⁻¹ mole⁻¹) was obtained from Bauer et al.⁷, based on an extrapolation of S₁₆⁰ = 0.028 cal. deg.⁻¹ mole⁻¹.

Melting Data.

The adopted heat of melting and the melting point were obtained from the enthalpy measurements by Shomate and Cohen.⁸ Powers and Blalock¹⁰ also found the heat of melting ΔH_m⁰ = 5.029 kcal. mole⁻¹ at 746°K. which is in good agreement with the adopted value.

Dec. 31, 1960; Mar. 31, 1966

S°_{298.15} = 11.574 cal. deg.⁻¹ mole⁻¹T_m = 744.3°K.T_b (monomeric gas) = 1803°K.ΔH_f°_{298.15} = -113.263 kcal. mole⁻¹ΔH_m° = 5.010 kcal. mole⁻¹ΔH_v° (to monomer) = 40.1 kcal. mole⁻¹Heat of Formation.

The heat of formation of LiOH(1) at 298.15°K. was obtained from that of the crystal by adding ΔH_m° and the difference between H°_{744.3}°_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The selected heat capacity of the liquid phase, C_p = 20.74 cal. deg.⁻¹ mole⁻¹, was obtained from the enthalpy measurements in the drop calorimeter by C. H. Shomate and A. J. Cohen, *J. Am. Chem. Soc.* **77**, 285 (1955).

W. D. Powers and O. C. Blalock, ORNL-1653, Oak Ridge Nat'l. Lab., have also determined the heat capacity of lithium hydroxide (1), C_p = 22.03 cal. deg.⁻¹ mole⁻¹, from the enthalpy measurements by the drop method.

The entropy (S°_{298.15} = 11.574 cal. deg.⁻¹ mole⁻¹) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See LiOH(c) table for details.

Vaporization Data.

The boiling point was calculated as the temperature at which the free energies of formation (ΔF_f°) for both LiOH(1) and LiOH(g) are equal. The difference in the heats of formation (ΔH_f°) of LiOH(1) and LiOH(g) at the boiling point is the heat of vaporization (ΔH_v°).

Heat of Formation

J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 535 (1960), have studied the equilibrium of Li₂O(c) + H₂O(g) system by the mass-spectrometric method. Using the reported equilibrium constants in the temperature range from 1100° to 1450°K, the heat of reaction Li₂O(c) + H₂O(g) → 2LiOH(g) at 298.15°K. has been calculated by both the second and the third law methods as 86.1 and 83.2 kcal. mole⁻¹, respectively. (The third law drift is -2.2 ± 2.6 e.u.) The third law value was taken for the calculation of the heat of formation of LiOH(g) at 298.15°K.

Heat Capacity and Entropy

Since the bond distance Li-F(g) (r_e = 1.56389 Å) was accurately measured from the microwave studies by L. Wharton, W. Klemperer, L. P. Gold, R. Strauch, J. J. Gallagher and V. E. Derr, J. Chem. Phys. 39, 1203 (1963), the bond distance Li-O in LiOH(g) was estimated by adding the bond length difference (0.04 Å) between H-OH(g) and H-F(g) to the bond distance Li-F(g). Also the bond distance Li-O(g) was estimated as 1.62 Å from the matrix-isolated infrared spectrum by D. White, K. S. Seshadri, D. P. Dever, D. E. Mann, M. J. Linevsky, J. Chem. Phys. 39, 2463 (1963). These two are in good agreement. The bond distance O-H was estimated from that in H₂O(g). The adopted bent molecular configuration with bond angle of 110° was proposed by S. H. Bauer, R. M. Diner and P. F. Porter, J. Chem. Phys. 29, 991 (1958). The three principal moments of inertia are I_A = [0.1237] × 10⁻³⁸, I_B = [2.1699] × 10⁻³⁹ and I_C = [2.2936] × 10⁻³⁹ g. cm.²

The Li-O stretching frequency was estimated to be the same as that in Li₂O(g) (ν = 987 cm.⁻¹, see Li₂O(g) table). The bending and the O-H stretching frequencies were estimated by comparison with H-OH, D-OH and T-OH which indicate rapid convergence to a constant as a heavier atom is attached.

Heat of Formation

The heat of formation is based on the following estimates. The relation D₀^o(M-X)/D₀^o(M-X) = 0.46 ± 0.03 for several alkaline earth dihalides has been reported by R. A. Kent, J. D. McDonald and J. L. Margrave, J. Phys. Chem. 70, 874 (1966). Assuming that this relation applies to hydroxides, we may estimate D₀^o(Mg-OH) = 87 ± 12 kcal/mol. A value of D₀^o(Mg-OH) = 105 ± 12 kcal/mol is obtained by comparison with D₀^o(Be-OH) ≤ 111 ± 10, D₀^o(Ca-OH) = 100 ± 10 and D₀^o(Sr-OH) = 95 ± 10 kcal/mol. The value for BeOH is from the JANAF tables, while those for CaOH and SrOH are from flame studies of L. V. Gurvich, private communication, High Temperature Institute, Moscow, 1966. The average value of D₀^o(Mg-OH) = 96 kcal/mol is used to calculate the heat of formation.

A value of D₀^o(Mg-OH) = 56 ± 5 kcal/mol was derived from intensity measurements on the flame spectrum of magnesium by E. M. Bulewicz and T. M. Sugden, Trans. Faraday Soc. 55, 770 (1959). This appears to be too small.

Heat Capacity and Entropy

The ground state is assumed to be ²Σ by analogy with isoelectronic MgF. Ultraviolet emission spectra near 3000 Å were observed for MgOH and MgOD by D. Pesic and A. G. Gaydon, Proc. Phys. Soc. (London) 73, 244 (1959), and L. Brewer and S. Trajmar, J. Chem. Phys. 35, 1585 (1962). Vibrational and rotational analyses were not performed. Assuming that the observed spectra correspond to the transition A²Π ← X²Σ, we estimate the first excited state at 27000 cm⁻¹. The vibrational frequencies ν₁ and ν₃ are estimated from those of H₂O(g) and MgO(g). The ν₂ is tentatively estimated at 1000 cm⁻¹.

A linear structure is assumed by use of the prediction of A. D. Walsh, J. Chem. Soc. 1953, 2288 (1953), for "HAg" molecules with less than 11 valence electrons (MgOH has 9 valence electrons). Confirmation of this prediction is scanty for molecules having "A" as the most electronegative element; however, recent microwave evidence [R. L. Kuczkowski, D. R. Lide, Jr., and L. C. Krishner, J. Chem. Phys. 44, 3131 (1966)] for the linearity of KOH and CaOH confirms the prediction for these molecules having 9 valence electrons. The O-H bond distance is assumed to be the same as that of H₂O(g) and the Mg-O bond distance is estimated from that of MgO(g).

MAGNESIUM MONOHYDROXIDE UNIPosITIVE ION (MgOH⁺) (IDEAL GAS)

Point Group [C_{∞v}]

S°_{298.15} = [51.9 ± 2] gibbs/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω_i, cm⁻¹

[800] (1)

[900] (2)

[3500] (1)

O-H = [0.98] Å

Bond Distance: Mg-O = [1.8] Å

Bond Angle: Mg-O-H = [180°]

Rotational Constant: B₀ = [0.4755] cm⁻¹

Heat of Formation

The gaseous molecules NaOH, MgOH and AlOH have 8, 9 and 10 valence electrons, respectively. Due to the similarity in molecular structure, we assume that the ionization potential (IP) of MgOH is approximately the average of IP(NaOH) and IP(AlOH). Adopting IP = 9 and 7.5 eV for NaOH (1) and AlOH (2), respectively, we obtain IP(MgOH) = 8.5 eV. Based on this value and ΔH°_f(MgOH, g) = -52 ± 20 kcal/mol we derive ΔH°_f(MgOH⁺, g) = 143 ± 40 kcal/mol which is tentatively adopted. The estimated value IP(MgOH) is close to IP(MgF) = 7.8 ± 0.3 eV (1), where MF and MgOH are isoelectronic molecules, and thus confirms the value within its uncertainty.

Heat Capacity and Entropy

Walsh (3) predicted that ABH molecules (H = hydrogen atom) containing 10 or less valence electrons will be linear in their ground state. Since MgOH⁺ molecule has 8 valence electrons, we assume it to be linear. The vibrational frequencies are estimated by comparison with those for NaOH(g) and MgOH(g). The O-H bond distance is assumed to be the same as that in H₂O(g). The Mg-O bond distance is estimated (4). The moment of inertia is 5.874 × 10⁻³⁹ g cm². The ground state quantum weight is assumed to be the same as that of NaOH(g). The enthalpy at 0°K is -2.24 kcal/mol.

Dec. 31, 1960; Dec. 31, 1965

Ground State Configuration $3 \Sigma^-$
 $S_{298.15}^\circ = 43.3 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^\circ = 81.0 \pm 2.5 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ = 298.15 = 81.0 \pm 2.5 \text{ kcal. mole}^{-1}$

Electronic Level and Quantum Weight

$$\frac{E_i}{0} \text{ cm.}^{-1} \frac{g_i}{3}$$

$\omega_e = 3315 \text{ cm.}^{-1}$
 $\omega_e x_e = 94.7 \text{ cm.}^{-1}$
 $\omega_e = 16.6684 \text{ cm.}^{-1}$
 $\alpha_e = 0.646 \text{ cm.}^{-1}$
 $\sigma = 1$
 $r_e = 1.038 \text{ \AA}$

Heat of Formation.

The value, $\Delta H_f^\circ(298, \text{NH}, g) = 81.0 \pm 2.5 \text{ kcal. mole}^{-1}$, was calculated from the selected dissociation energy, $D_0 = 83 \pm 2 \text{ kcal. mole}^{-1}$, based on the following investigations. J. L. Franklin, V. H. Dibel, R. M. Reese and M. Krause, J. Am. Chem. Soc. 80, 298 (1958) and R. I. Reed and W. Snedden, J. Chem. Soc. 4132 (1959) have determined the dissociation energy of $\text{NH}(g)$ by electron impact as $83 \pm 2 \text{ kcal. mole}^{-1}$ and $85.3 \pm 6 \text{ kcal. mole}^{-1}$, respectively. A. L. Companion and F. O. Ellison, J. Chem. Phys. 32, 1132 (1960), and P. C. H. Jordan and H. C. Lonquet-Higgins, Mol. Phys. 5, 121 (1962) have calculated theoretically the dissociation energy by a semi-empirical method and obtained $83.3 \text{ kcal. mole}^{-1}$ and $81.2 \text{ kcal. mole}^{-1}$, respectively. These results are in good agreement. G. Herzberg, "Spectra of Diatomic Molecules", 2nd Ed., D. Van Nostrand Company, New York, 1950, has estimated the dissociation energy $D_0(\text{NH}, g) = 3.8 \text{ e.v.}$ ($87.6 \text{ kcal. mole}^{-1}$) based on the average of two earlier theoretical calculations by R. S. Mulliken, ($D_0 = 4.2 \text{ e.v.}$), Rev. Mod. Phys. 4, 1 (1932) and O. King ($D_0 = 3.4 \text{ e.v.}$), J. Chem. Phys. 5, 378 (1938). A. G. Gaydon, "Dissociation Energies", 2nd Ed. Chapman & Hall Ltd, London, 1953, favored O. Glockler's estimation $D_0 = 86.3 \text{ kcal. mole}^{-1}$ which was based upon the comparison of force constants and D values of related hydrides (i.e. CH, OH and FH).

Heat Capacity & Entropy.

The rotational constants B_e and α_e were obtained from R. N. Dixon, Can. J. Phys. 37, 1171 (1959). The vibrational constants ω_e and $\omega_e x_e$ were calculated from Dixon's data: $B_e = 16.6684 \text{ cm.}^{-1}$, $D_e = 16.85 \times 10^{-4} \text{ cm.}^{-1}$ and $\omega_e = 3125.6 \text{ cm.}^{-1}$ by the relation $D_e = 4 B_e^2 / \omega_e^2$ and $\omega_e = \omega_e - 2 \omega_e x_e$.

D. E. Milligen and M. E. Jacox, J. Chem. Phys. 41, 2838 (1964) have observed from the spectrum of NH the vibrational fundamental $\omega = 3135 \pm 2 \text{ cm.}^{-1}$ in Ar and N_2 matrices. K. Rosengren and O. C. Flamentel, J. Chem. Phys. 43, 507 (1965) also reported $\omega = 3122.2 \pm 0.6 \text{ cm.}^{-1}$ in N_2 matrix and $\omega = 3131.6 \pm 0.4 \text{ cm.}^{-1}$ in Ar matrix.

NITROXYL HYDRIDE (HNO)

(IDEAL GAS)

Point Group C_s
 $\Delta H_f^\circ 0 = 24.5 \text{ kcal. mole}^{-1}$
 $S_{298.15}^\circ = 52.729 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^\circ 298.15 = 23.8 \text{ kcal. mole}^{-1}$
 Ground State Multiplicity = [1]

Vibrational Frequencies and Degeneracies

ω , cm. ⁻¹	σ
2854.17 (1)	2954.17 (1)
1570 (1)	1570 (1)
1110 (1)	1110 (1)

Bond Distance: H-N = $1.020 \pm 0.02 \text{ \AA}$ N=O = $1.239 \pm 0.005 \text{ \AA}$ Bond Angle: H-N-O = $114^\circ 25' \pm 2^\circ$ Product of the Moments of Inertia: $I_A I_B I_C = 5.939 \times 10^{-118} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation

$\Delta H_f^\circ 298.15$ for HNO(g) was calculated from D(H-NO) = $48.6 \text{ kcal. mole}^{-1}$ at 0°K. reported by M. J. Y. Clement and D. A. Ramsay, Can. J. Phys. 39, 205 (1961).

Heat Capacity and Entropy

Vibrational frequencies were assigned by J. L. Bancroft, J. M. Hollis and D. A. Ramsay, Can. J. Phys. 40, 322 (1962) and H. Brown and G. Pimental, J. Chem. Phys. 29, 883 (1958). Bond distances and bond angles were taken from J. L. Bancroft, J. M. Hollis, and D. A. Ramsay, loc. cit. The molecular constants given by F. W. Dalby, Can. J. Phys. 35, 1336 (1958) were: $r(\text{N-O}) = 1.216 \text{ \AA}$, $r(\text{N-H}) = 1.0628 \text{ \AA}$, and $\angle \text{HNO} = 108.5^\circ$. The three principal moments of inertia are: 1.262×10^{-40} , 2.1067×10^{-39} , and $2.2330 \times 10^{-39} \text{ g. cm.}^2$.

Heat of Formation

P. O. Ashmore and B. J. Tyler, J. Chem. Soc. 1017 (1961) reported $\Delta H_f^{298.15} = -9.06 \pm 0.32$ kcal. mole⁻¹ for the reaction: NO(g) + NO₂(g) + H₂O(l) = 2HNO₂(g), yielding $\Delta H_f^{298.15} = -18.57 \pm 0.20$ kcal. mole⁻¹ for HNO₂(g). L. H. Jones, R. M. Badger and G. E. Moore, J. Chem. Phys., 19, 1599 (1951) estimated the difference in energy of cis- and trans-HNO₂(g) to be 506 ± 250 cal. mole⁻¹. Hence the value of $\Delta H_f^{298.15}$ for cis-HNO₂(g) was calculated.

The heat of reaction and the equilibrium constants for the formation of HNO₂(g) have been calculated by M. M. Karvanev and O. A. Skvortsov, Russ. J. Phys. Chem. 36, 566 (1962). The value of $\Delta H_f^{298.15}$ reported is -18.6 kcal. mole⁻¹. However, based on the heat of formation of liquid HNO₂, P. O. Ashmore and B. P. Levitt, Trans. Faraday Soc., 53, 945 (1957) give $\Delta H_f^0 = -13.7$ kcal. mole⁻¹. The corresponding value reported by W. A. Rösser and H. Wise, J. Chem. Phys., 26, 571 (1957) is -20.0 kcal. mole⁻¹, based on the experimental data of L. O. Wayne and D. M. Yost, J. Chem. Phys., 19, 41 (1951), and the entropy of the equilibrium mixture of the trans- and cis-HNO₂(g) calculated by L. H. Jones, R. M. Badger and G. E. Moore, loc. cit.

Heat Capacity and Entropy

Vibrational frequencies, bond distances, and bond angles were obtained from L. Dor and P. Tarte, Bull. Soc. Roy. Sci., LG. 478 (1951) and L. H. Jones, R. M. Badger and G. E. Moore, loc. cit. The three principal moments of inertia are: 1.0271 X 10⁻³⁹, 6.8242 X 10⁻³⁹, and 7.8520 X 10⁻³⁹ g. cm.²

Heat of Formation.

P. O. Ashmore and B. J. Tyler, J. Chem. Soc. 1017 (1961) reported ΔH_f^o 298.15 = -9.06 ± 0.32 kcal. mole⁻¹ for the reaction: NO(g) + NO₂(g) + H₂O(g) = 2HNO₂(g), yielding ΔH_f^o 298.15 = -18.57 ± 0.20 kcal. mole⁻¹ for HNO₂(g). L. H. Jones, R. M. Badger and O. E. Moore, J. Chem. Phys., 19, 1599 (1951) estimated the difference in energy of cis- and trans-HNO₂(g) to be 506 ± 250 cal. mole⁻¹. Hence the value of ΔH_f^o 298.15 for trans-HNO₂(g) was calculated.

The heat of reaction and the equilibrium constants for the formation of HNO₂(g) have been calculated by M. Kervaeve and G. A. Skvortsov, Russ. J. Phys. Chem. 35, 566 (1962). The value of ΔH_f^o 298.15 reported is -18.8 kcal. mole⁻¹. However, based on the heat of formation of liquid HNO₂, P. O. Ashmore and B. F. Levitt, Trans. Faraday Soc., 53, 945 (1957) give ΔH_f^o = -13.7 kcal. mole⁻¹. The corresponding value reported by W. A. Rosser and H. Wise, J. Chem. Phys., 25, 571 (1957) is -20.0 kcal. mole⁻¹, based on the experimental data of L. G. Wayne and D. M. Yeat, J. Chem. Phys. 19, 41 (1951), and the entropy of the equilibrium mixture of the trans- and cis-HNO₂(g) calculated by L. H. Jones, R. M. Badger and O. E. Moore, loc. cit.

Heat Capacity and Entropy.

Vibrational frequencies, bond distances, and bond angles were taken from L. H. Jones, R. M. Badger, and O. E. Moore, loc. cit. The values of vibrational frequencies were in good agreement to those reported by L. Dor and P. Tarte, Bull. Soc. Roy. Sci., 478 (1951). The three principal moments of inertia are: 7.860 × 10⁻⁴⁰, 7.5268 × 10⁻³⁹, and 8.3129 × 10⁻³⁹ g. cm.²

Heat of Formation.

ΔH_f^o 298.15 was taken from National Bureau of Standards Report 7437, January 1, 1962. Equilibria involving HNO₃ were measured by E. J. Jones, J. Am. Chem. Soc. 55, 2274 (1933), G. Feick, J. Am. Chem. Soc. 76, 5858 (1954) and H. E. Abel, H. Schmid and M. Stein-Wien, Z. Elektrochem. 35, 692 (1930), yielding ΔH_f^o = -32.06, -32.02, and -32.09 kcal. mole⁻¹, respectively. O. Becker and W. A. Roth, Z. Elektrochem. 40, 836 (1934) and J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882-1886, measured the heat of neutralization of HNO₃(aq.) with NH₃, combining these values with the data for NH₄NO₃ yields ΔH_f^o = -32.27 and -32.07 kcal. M. Berthelot, "Sur la Force des Matieres Explosives," 3rd. ed., Paris, 1883, measured the heat of reaction of N₂O₄(g) and Cl₂(g), obtaining ΔH_f^o = -32.10 kcal. mole⁻¹. The value of ΔH_f^o 298.15 reported by W. R. Forsythe and W. P. Cissaque, J. Am. Chem. Soc. 64, 48 (1942) was -31.994 kcal. mole⁻¹. The value adopted is the weighted average of these six values.

Heat Capacity and Entropy.

Vibrational frequencies were obtained from A. Palm and M. Kilpatrick, J. Chem. Phys. 23, 1562 (1955). Bond distances and bond angles were taken from D. J. Millen and J. R. Morton, J. Chem. Soc., 1523 (1960). The basic parameters of HNO₃(g) reported by P. A. Akshin, L. V. Vilkoy and V. Y. Rosolovskii, Zhur. Strukt. Khim. 1, 1 (1960) were: r(N-O) = 1.22 ± 0.01 Å; r(N-O) = 1.40 ± 0.01 Å and ∠ O-N-O = 135° ± 2.5°. Forsythe and Cissaque, loc. cit. have calculated the absolute entropy of pure nitric acid (g) from calorimetric data. The value obtained was S_{298.15} = 63.62 cal. deg.⁻¹ mole⁻¹. The entropy of nitric acid vapor at 298.1°K. has also been computed by H. Cohn, C. K. Ingold, and H. G. Poole, J. Chem. Soc. 4272 (1952) to be 63.70 cal. deg.⁻¹ mole⁻¹. The three principal moments of inertia are: 6.4299 × 10⁻³⁹, 7.0314 × 10⁻³⁹, and 1.3461 × 10⁻³⁸ g. cm.²

$$\Delta F_f^o = -13.49 \pm 0.02 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^o = 9.564 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_d = [700]^{\circ}\text{K.}$$

Heat of Formation.

ΔH_f^o 298.15 was obtained from S. R. Gunn and L. G. Green, *J. Am. Chem. Soc.* **80**, 4762 (1958). The value of ΔH_f^o 298.15 reported by C. E. Messer, L. G. Fasolino and C. E. Thalmeier, *J. Am. Chem. Soc.* **77**, 4524 (1955) was -13.60 $\pm$ 0.27 kcal. mole⁻¹ which is in excellent agreement with the value given by S. R. Gunn and L. G. Green, loc. cit. The results of the previous investigations were also reviewed by C. E. Messer, et al., loc. cit.

Heat Capacity and Entropy.

C_p below 350°K were measured by E. F. Westrum, et al., University of Michigan, Ann Arbor, Michigan, private communication, May 19, 1960. C_p above 350°K were estimated by comparison with those for LiH(c). C_p 59.94 $\sim$ 91.84°K., were also measured by E. V. Sayre and J. J. Heaver, *J. Chem. Phys.* **19**, 584 (1950). S^o at 100°, 200°, and 298.15° were taken from E. F. Westrum, et al., loc. cit., using $S_{10}^o(\text{extrap.}) = 0.008 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Temperature of Decomposition.

T_d was estimated from the value of ΔF_f^o in the table. The value of T_d given by D. M. Banas, J. J. McSharry and E. A. Sullivan, *J. Am. Chem. Soc.* **77**, 2007 (1955) was 940°K. It was assumed that NaH would behave similarly to LiH and that decomposition pressure would be purity dependent, and this would produce apparently high T_d 's.

Dec. 31, 1950; Mar. 31, 1966

$\Delta H_f^\circ 0 = -100.82 \pm 0.1 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = -101.90 \pm 0.1 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ = 1.519 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ = 1.519 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 (\text{to monomer}) = [51.5] \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 (\text{to dimer}) = [49.0] \text{ kcal. mole}^{-1}$

Heat of Formation.

The standard enthalpy of formation, $\Delta H_f^\circ 298$ (NaOH, c) = $-101.90 \pm 0.1 \text{ kcal. mole}^{-1}$, was calculated from the heat of solution of sodium hydroxide (c) and the heat of sodium metal hydrolysis and the appropriate auxiliary data. N. A. Peshetnikov¹ has measured the heat of solution NaOH(c) $\rightarrow$ NaOH(400 H₂O) as $-10.445 \pm 0.015 \text{ kcal. mole}^{-1}$ at 298.15°K. by solution calorimetry. Using the auxiliary heat of dilution reported by V. B. Parker², the selected heat of solution of sodium hydroxide (c) at infinite dilution is $-10.555 \text{ kcal. mole}^{-1}$. Also L. E. Murch and W. F. Glaque³ measured calorimetrically the heat of solution of solid samples of NaOH·nH₂O in the range from n = 0.1 to 1.0. When extrapolated to n = 0 and infinite dilution², this result yields the heat of solution of NaOH(c) at infinite dilution, $\Delta H_f^\circ 298 = -10.635 \text{ kcal. mole}^{-1}$, which is in good agreement with the value selected.

The heat of sodium metal hydrolysis, $\Delta H_f^\circ 298$, has been measured in the solution calorimeter by the following investigators. Na(c) + H₂O(l) $\rightarrow$ NaOH(nH₂O) + 1/2 H₂(g) $\Delta H_f^\circ 298$

Source	Number of Moles of H ₂ O	$\Delta H_f^\circ 298$ kcal. mole ⁻¹	$\Delta H_f^\circ 298$ (NaOH·nH ₂ O) kcal. mole ⁻¹	$\Delta H_f^\circ 298$ (NaOH, c) kcal. mole ⁻¹
Gunn et al. ³	1000	-44.047 ± 0.008	-112.446	-101.899
Messer et al. ⁴	CO	-44.215 ± 0.20	-112.530	-101.975
Ketchen et al. ⁵	CO	-44.054 ± 0.20	-112.369	-101.814

The values of $\Delta H_f^\circ 298$ (NaOH·nH₂O) were calculated from the heats of reaction $\Delta H_f^\circ 298$ using the $\Delta H_f^\circ 298$ (H₂O, l) = $-68.315 \text{ kcal. mole}^{-1}$.⁶ Combination of the selected heat of solution of NaOH(c) at infinite dilution with the heat of formation of NaOH(COOH₂) gives the heat of formation of NaOH(c) in the last column of the table. A weighted average of these three measurements has been taken for the selected heat of formation of sodium hydroxide (c).

The earlier investigations have been reviewed by F. R. Bichowsky and F. D. Rossini⁷, and C. E. Messer et al.⁴, and these earlier reported data are not adopted in the tabulation.

Heat Capacity and Entropy.

L. E. Murch and W. F. Glaque¹¹ have measured low temperature heat capacities of NaOH·0.04014 H₂O and NaOH·0.9776 H₂O from 15° to 320°K. and calculated the values of C_p for the pure phase of NaOH(c). T. B. Douglas and J. L. Dever⁹ have measured the enthalpy changes from 273° to 975°K. in the drop calorimeter and derived the heat capacities. The low temperature and the high temperature heat capacities were joined smoothly by Murch and Glaque, and the smooth values were adopted in the tabulation. Low temperature heat capacities from 60° to 300°K. have also been measured by J. C. R. Kelly and P. E. Snyder⁷, whose data are in good agreement with those reported by Murch and Glaque. M. M. Popov and D. M. Ginzburg¹⁰ have determined the heat capacities of NaOH(c) in the temperature range from 298° to 577°K. from the enthalpy measurements by drop calorimetry. The reported $H_{500}^\circ - H_{298}^\circ = 3.112 \text{ kcal. mole}^{-1}$ is in good agreement with the tabulated value.

Transition and Melting Data.

The adopted heat of transition and the transition temperature, and the adopted heat of melting and the melting point were obtained from Douglas and Dever,⁹ Popov and Ginzburg,¹⁰ reported the heat of transition $\Delta H_{tr}^\circ = 1.930 \text{ kcal. mole}^{-1}$ at 576.8°K. and the heat of melting $\Delta H_m^\circ = 1.629 \text{ kcal. mole}^{-1}$ at 595.16°K.

Heat of Sublimation.

See NaOH(g) table for details.

$$\Delta H_f^o 298.15 = -99.998 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^o = 1.519 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^o(\text{to monomer}) = 37.9 \text{ kcal. mole}^{-1}$$

Heat of Formation.

The heat of formation of NaOH(l) at 298°K. was obtained from that of the crystal by adding ΔH_m^o and the difference between $H_{298.15}^o$ for crystal and liquid.

Heat Capacity and Entropy.

The selected heat capacities in the temperature range from 592.3° to 1000°K. were obtained from the enthalpy measurements of sodium hydroxide (l) in the drop calorimeter by T. B. Douglas and J. L. Dever¹. The heat capacities below the melting point and above 1000°K. were extrapolated from the selected heat capacity curve.

Douglas and Dever¹ have also compared their heat capacity values with those from W. D. Powers and G. C. Blalock² who have applied the same drop method to determine the heat capacities of NaOH(l). Both results are in reasonable agreement. M. M. Popov and G. M. Ginzburg³ applying the same technique obtained different values of heat capacity. The smoothed enthalpy data reported by Ginzburg⁴ are 200 to 500 cal. mole⁻¹ smaller than the tabulated values at the temperature range from 700° to 1000°K.

The entropy ($S_{298}^o = 17.65 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See NaOH(c) table for details.

Vaporization Data.

The boiling point 1652.7°K. was calculated as the temperature at which the free energies of formation (ΔF_f^o) for both NaOH(l) and NaOH(g) are equal. The difference in the heats of formation (ΔH_f^o) of NaOH(l) and NaOH(g) at the boiling point is the heat of vaporization. If $\text{Na}_2\text{O}(\text{H})_2(\text{g})$ is also considered as a minor component in the vapor mixture (approximately 6% of total vapor pressure at the boiling point) the calculated boiling point is 1653°K. (see NaOH(g) table for details).

H. von Wartenberg and P. Albrecht, Z. Elektrochem. 27, 162 (1921), have studied the vapor pressures of liquid NaOH and reported the boiling point as 1661°K.

Bond Distance: Na-O = [1.97] Å

Bond Angle: Na-O-H = [110°]

Product of the Moments of Inertia: $I_A I_B I_C = [5.3082] \times 10^{-117} \text{ g.}^3 \text{ cm.}^6$ $\sigma = 1$

Heat of Formation.

R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. **29**, 454 (1958), have found in their mass-spectrometric studies that the NaOH(l) vaporizes mainly as gaseous dimer in the temperature range from 575° to 723°K. They have also calculated by the slope method the heat of dimerization, $\Delta H_{298}^0 = -54 \pm 5 \text{ kcal. mole}^{-1}$, for $2\text{NaOH(g)} = \text{Na}_2\text{(OH)}_2\text{(g)}$ and the heat of sublimation, $\Delta H_{298}^0 = 46.3 \pm 3 \text{ kcal. mole}^{-1}$, for $\text{NaOH(c)} = \text{NaOH(g)}$. The second law values were determined using ion intensity ratios, however, a third law calculation using a single data point converted by the authors to absolute pressure (J. Phys. Chem. **62**, 488 (1958)) yields $\Delta H_{298}^0 = -51.6 \text{ kcal. mole}^{-1}$, ΔH_{298}^0 (to monomer) = $-49.5 \text{ kcal. mole}^{-1}$ and ΔH_{298}^0 (to dimer) = $-41.1 \text{ kcal. mole}^{-1}$, which are in agreement within the limit of uncertainty. Later, Porter and Schoonmaker, J. Chem. Phys. **31**, 830 (1959), found the activity of molten alkali hydroxide had been reduced in the presence of MgO in their sample container, and the uncertainty in the heat of sublimation might be $\pm 5 \text{ kcal. mole}^{-1}$, but the heat of dimerization should not be seriously affected because it was calculated from alcohols of both species. In order to have good agreement between the calculated total pressure of monomer and dimer of sodium hydroxide (g) and the observed vapor pressures by H. von Wartenberg and P. Albrecht, Z. Elektrochem. **27**, 182 (1921), the heat of dimerization and the heat of sublimation have been so chosen as $\Delta H_{298}^0 = -54 \text{ kcal. mole}^{-1}$ and $\Delta H_{298}^0 = 46.3 \text{ kcal. mole}^{-1}$ = 51.5 kcal. mole⁻¹, respectively, which are still within the limit of Porter and Schoonmaker's data. The calculated boiling point is 1653°K. which is in good agreement with 1661 ± 20°K. reported by Wartenberg and Albrecht, loc. cit. The heats of formation were calculated from the selected heat of dimerization and heat of sublimation as ΔH_{298}^0 (NaOH, g) = $-50.4 \text{ kcal. mole}^{-1}$ and ΔH_{298}^0 (Na₂(OH)₂, g) = $-154.8 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The bent molecular configuration with the bond angle of 110° was proposed by S. H. Bauer, R. M. Diner and P. F. Porter, J. Chem. Phys. **23**, 931 (1958). The bond distance O-H was estimated from that in H₂O(g). The bond distance Na-O was estimated by adding the bond length difference (0.04 Å) between H-OH(g) and H-F(g) to the bond distance Na-F(g) (1.9259 Å) which has been accurately measured by R. K. Bauer and H. Lew, Can. J. Phys. **41**, 1461 (1963). The Na-O stretching frequency was obtained from L. H. Spinar and J. L. Margrave, Spectrochim. Acta **12**, 244 (1956), in the infrared spectroscopic studies. The O-H stretching and the bending frequencies were estimated by comparison with H-OH, D-OH and T-OH which indicate rigid convergence to a constant as a heavier atom is attached. The three principal moments of inertia are $I_A = [0.1252] \times 10^{-59}$, $I_B = [6.449] \times 10^{-59}$ and $I_C = [6.5742] \times 10^{-59} \text{ g. cm.}^2$.

Heat of Formation.

P. Orty, Trans. Farad. Soc. **55**, 408 (1959) has summarized the determinations of the heat of formation of OH and concludes that the short extrapolation by Barrow, Arkiv. Fysik, **11**, 281 (1956) of the $E(\sum^+)$ $\rightarrow A(\sum^+)$ system gives the most reliable result. The value of $D_0 = 101.33 \text{ kcal. mole}^{-1}$ was adopted and leads to a heat of formation of $9.432 \text{ kcal. mole}^{-1}$. A recent determination of the dissociation energy from measurements of the concentration of the radicals in water oxygen mixtures by A. P. Furmal and A. V. Frost, Vesh. Mosk. Univ., Ser. II Khim. **15**, 25 (1961) gives $\Delta H_f^{\circ}(\text{OH}) = 102.8 \pm 0.8 \text{ kcal. mole}^{-1}$ in good agreement with the adopted value. Also V. A. Medvedev, V. V. Korobov and V. P. Baluz, Zhur. Fiz. Khim. **33**, 58 (1959) reported a heat of dissociation of $102.2 \pm 1 \text{ kcal. mole}^{-1}$ from dissociation of water in a spherical bomb.

Heat Capacity and Entropy.

The molecular constants were all given by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc. New York, 1950. This calculation gives values in excellent agreement with L. Haar, A. S. Friedman and C. W. Beckett, National Bureau of Standards Monograph No. 20, May 1961. The agreement with the higher order correction calculations of H. L. Johnston, J. Belzer and L. Savedoff, TR 316-5, Ohio State University, available as ATI 139 967, is good between 298 and 4000°K. This earlier work uses different constants and also a different value of the ground state splitting constant, but at 6000°K. the entropy difference is still less than 0.25%.

HO⁺

HYDROXYL UNIPOSITIVE ION (OH⁺) (IDEAL GAS) MOL. WT. = 17.0068

Ground State Configuration $3 \sum^-$
 $\Delta H_f^o = 313.3 \pm 2.5 \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = 43.657 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^o 298.15 = 314.0 \pm 2.5 \text{ kcal. mole}^{-1}$

Electronic Levels and Multiplicities

$$\frac{\epsilon_i, \text{ cm.}^{-1}}{\epsilon_i, \text{ cm.}^{-1}} \frac{g_i}{3}$$

$$\omega_e x_e = \{74\}$$

$$\sigma_e = 0.732 \text{ cm.}^{-1}$$

$$r_e = 1.0289 \text{ \AA}$$

Heat of Formation.

The ionization potential of hydroxyl has been determined by M. M. Mann, A. Hustrulid and J. T. Tate, Phys. Rev. 58, 340 (1940) from electron impact data on water vapor, as 13.6 e.v. S. N. Foner and R. L. Hudson, J. Chem. Phys. 25, 602 (1956) have measured the appearance potential of OH⁺ from OH as 13.18 ± 0.1 e.v. (303.96 kcal.). This value was the one adopted to obtain the heat of formation of OH⁺(g) from that of OH(g) at 0°K.

Heat Capacity and Entropy.

The molecular constants, with the exception of $\omega_e x_e$, were all given by O. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc. New York, 1950. The value of $\omega_e x_e$ was estimated by analogy with OH(g) and other diatomic hydrides.

The value of H_{298}^o at 0°K. is -2.06 kcal. mole⁻¹.

 $\sigma x_e = [0.65] \text{ cm.}^{-1}$

Heat of Formation

L. M. Branscomb, Joint Institute for Laboratory Astrophysics Report No. 62, Feb. 1st, 1966 has deduced an electron affinity of OH of $1.83 \pm 0.04 \text{ e.v.}$ ($42.2 \pm 0.9 \text{ kcal.}$) from the photodetachment spectrum of OH⁻(g). The vibrational state was deduced to be the ground state since no other absorption sequences could be detected by a thorough search. F. M. Page, Faraday Soc. Discussions 13, 87 (1955) has reviewed the methods and results of earlier determinations of the electron affinity of OH(g) and concludes that it is $65 \pm 1 \text{ kcal.}$ However he does state that it is not generally known whether the flame systems chiefly investigated are in thermodynamic equilibrium. In a later paper F. M. Page and T. M. Sugden, Trans. Faraday Soc. 53, 1092 (1957) conclude that much higher concentrations of radicals are obtained in flames than predicted thermodynamically. However for certain systems at lower temperatures they estimate only a factor of 3 increase in concentration and thus calculate the electron affinity as $61 \text{ kcal. mole}^{-1}$. The value reported by Branscomb, loc. cit. is adopted here.

Heat Capacity and Entropy

Branscomb loc. cit. has used his photodetachment spectra to obtain values of ω_e , B_e and r_e for OH⁻(g) which are remarkably similar to those for OH(g). The values of $\omega_e x_e$ and σx_e were estimated by comparison with OH(g) and other hydrides. The ground state configuration was assumed to be that of HF(g) with which it is isoelectronic. The value of H_m-H_{298} at 0°K. is $-2.057 \text{ kcal. mole}^{-1}$.

1101	(1)
3414	(1)

Bond length: H-O = [0.958] Å O-O = [1.30] Å
Bond angle: HOO = [120°] σ = 1

Product of the Moments of Inertia: I_AI_BI_C = [0.6424] X 10⁻¹¹⁷ g.³ cm.⁶

Heat of Formation.

S. N. Foner and R. L. Hudson, J. Chem. Phys. 36, 2681 (1962) have determined the ionization potential of HO₂ and the appearance potential of HO₂⁺ from H₂O₂. Using the ΔH°_f of H₂O₂(g) determined by P. A. Giguere and I. D. Liu, J. Am. Chem. Soc. 77, 6477 (1955), they calculate ΔH°_f O HO₂ = 5.7 ± 2 kcal. mole⁻¹.

Heat Capacity and Entropy.

The point group must be C₁ as the two oxygen atoms have been shown to be non-equivalent, from the increased number of infra-red bands obtained when using O₁₆ enriched with 28% of O₁₈, by D. E. Milligen and M. E. Jacox, J. Chem. Phys. 39, 2027 (1963). They also reported the three frequencies given above in the infra-red spectrum of the matrix isolated HO₂ radical. The bond lengths were taken equal to those estimated by M. E. Boyd, J. Chem. Phys. 37, 1317 (1962), the angle was that recommended by Milligen and Jacox, loc. cit. Boyd's conclusion that the lowest energy configuration should be an isosceles triangle could not be accepted in view of the nonequivalence of the oxygen atoms. The electronic ground state was taken as 2A" as predicted by A. D. Walsh, J. Chem. Soc. London, 2288 (1953).

[7650]	2	[38110]	2
[15150]	1	[57490]	1

Heat of Formation

Jordan (1) estimated the dissociation energy (D₀) of PH(g) as 70.44 kcal/mol using a semiempirical theoretical method. The corresponding value for the heat of formation (ΔH_{f,298.15}) is 60.6 ± 8 kcal/mol.

Heat Capacity and Entropy

Jordan (1) predicted five electronic levels (X²Σ, A²Σ, B²Σ, D²Σ, E²Σ) based on the reported value (2) of 29560 cm⁻¹ for the C²Δ level (this level is designated A₁₁ by Herzberg (2)). Several qualitative spectroscopic investigations of PH(g) have been reported and are in general accord with the predictions of Jordan (1). Ishaq and Pearsa (3) reported the values of the rotational constant B₀ and the fundamental vibrational frequency ω₀. The value of ω₀ is calculated from the Morse potential function. The bond distance is calculated from B₀. The value of the anharmonic vibrational term ω_xx_e is estimated from the relation ω_xx_e = ω₀²/(4D₀ + 2ω₀).

June 30, 1982

Heat of Formation. ΔH_f° 298.15 was calculated from the dissociation energy of PbH(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration and spectroscopic data were obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York (1950). Electronic levels and multiplicity were estimated by comparison with those for PbF(g).

Mol. Wt. = 208.22

 ΔH_f° 298.15 = 56.5 ± 4.6 kcal. mole⁻¹ S° 298.15 = 52.737 cal. deg⁻¹ mole⁻¹Ground State Configuration $2\pi_{1/2}$

Electronic Levels and Multiplicities

$$\frac{\epsilon, \text{ cm.}^{-1}}{[\infty]} = \frac{\frac{g_1}{2}}{2}$$

$$\omega_e = 1564.1 \text{ cm.}^{-1} \quad \omega_e x_e = 29.75 \text{ cm.}^{-1}$$

$$B_e = 4.971 \text{ cm.}^{-1} \quad \alpha_e = 0.144 \text{ cm.}^{-1}$$

$$0^- = 1$$

SULFUR MONOHYDRIDE (SH)

(IDEAL GAS)

GFW = 33.07197

Ground State Configuration $2^1\pi$

$$\Delta H^\circ_{\text{f}0} = 34.4 \pm 4 \text{ kcal/mol}$$

$$S^\circ_{298.15} = 46.73 \text{ gibbs/mol}$$

$$\Delta H^\circ_{298.15} = 34.6 \pm 4 \text{ kcal/mol}$$

Electronic Levels and Quantum Weights

$\frac{\epsilon_i, \text{cm}^{-1}}{0}$	$\frac{g_i}{2}$	$\frac{\epsilon_i, \text{cm}^{-1}}{59636}$	$\frac{g_i}{2}$
376.9	2	[63850]	4
30682.4	2	75000	18
$\omega_e = 2702 \text{ cm}^{-1}$	$\omega_e x_e = 60 \text{ cm}^{-1}$	$\sigma = 1$	
$B_e = 9.611 \text{ cm}^{-1}$	$\alpha_e = [0.3] \text{ cm}^{-1}$	$r_e = 1.3397 \text{ \AA}$	

Heat of Formation

Mackie (1) estimated $\Delta H^\circ_{\text{f}298}$ of SH(g) as 34.6 ± 4 kcal/mol, this value being an average of three independent determinations.

He obtained these three values by the following methods: (A) He calculated $\Delta H^\circ_{\text{f}298}$ of SH(g) as 34.9 ± 4.5 kcal/mol from $\Delta H^\circ_{\text{f}298}$ of thiobenzyl alcohol (g), $\Delta H^\circ_{\text{f}298}$ of the benzyl radical (g) and the heat of dissociation (D°) of thiobenzyl alcohol reported by Sehon and Darwent (2). (B) A value of 35.2 ± 4.5 kcal/mol was calculated from $\Delta H^\circ_{\text{f}298}$ of C_2H_5 (g), $\Delta H^\circ_{\text{f}298}$ of $\text{C}_2\text{H}_5\text{SH}$ (g) and the appearance potential of C_2H_5 reported by Franklin and Lumpkin (3). (C) He calculated that $\Delta H^\circ_{\text{f}298}$ of SH(g) is 33.7 ± 3 kcal/mol from $\Delta H^\circ_{\text{f}298}$ of H_2S (g) and the mass spectrographic data for the reactions $\text{H}_2\text{S} = \text{SH}^\bullet + \text{H} + e^-$ and $\text{SH} = \text{SH}^+ + e^-$ reported by Palmer and Lossing (4). The adopted value of 34.5 ± 4 kcal/mol compares with a value of 34.9 kcal/mol obtained from a linear Birge-Sponer extrapolation of the potential function.

Heat Capacity and Entropy

The high resolution spectra of SH(g) have been studied by Ramsay (5) and Johns and Ramsay (6) in the near UV and by Morrow (7) in the vacuum UV. The energy levels of the doublet ground state and of the first excited state ($^2\pi$) were reported by Ramsay (5). Six of the seven higher excited levels ($8^2\pi$, $9^2\pi$, $10^2\pi$, $11^2\pi$, $12^2\pi$, $13^2\pi$) were reported by Morrow (7), the last five of which are shown as an average of 75000 cm^{-1} . The remaining electronic level ($14^2\pi$) is estimated by analogy with the electronic levels of SD(g) reported by Morrow (7).

Ramsay (5) reported the following rotational and vibrational constants: $B_0 = 9.461 \text{ cm}^{-1}$, $\omega_e = 2702 \text{ cm}^{-1}$, and $\omega_e x_e = 60 \text{ cm}^{-1}$. The value of α_e is calculated from the Morse potential function. The rotational constant B_0 is calculated from $B_e = B_0 + \alpha_e/2$. The bond distance is calculated from B_e .

Ground State Configuration [2Π]

ΔH°_f 0 = [123.7] kcal. mole⁻¹

S°_{298.15} = [51.638] cal. deg.⁻¹ mole⁻¹

ΔH°_f 298.15 = [123.4] kcal. mole⁻¹

Electronic Levels and Multiplicities

E ₁ , cm. ⁻¹	E ₁
0	[4]

ω_e x_e = [19] cm.⁻¹

δ_e = 1

ω_e = [5.1] cm.⁻¹

r_e = [1.821] Å

Heat of Formation.

ΔH°_f 0 was estimated as 123.7 kcal. mole⁻¹ by J. S. Oordon, Astroystema International, Livingston, New Jersey, private communication, January 10, 1963. ΔH°_f 298.15 was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Oordon, loc. cit. r_e was calculated from the relationship r_e = (16.858778/μB_e)^{1/2} Å.

Heat Capacities and Entropy

H. W. Woolley, R. B. Scott and P. G. Brickwedde, J. Research Nat. Bur. Standards 41, 379 (1946), calculated the thermodynamic functions by a method of direct summation for normal H₂ (75% ortho and 25% para) using spectroscopic constants derived from an analysis of U. V. band spectra. These constants are more preferable for use in a summation method than those obtained by G. Herzberg, Can. J. Res. A29, 144 (1950) from the measured quadrupole transitions in the ground state which accurately describe the lower vibrational levels only. In any case the difference in the functions resulting from the two sets of data are less than 0.3%.

Since the entropies of Woolley et al. contain a contribution from nuclear spin, a correction of -Rln4 was applied. However, the entropy due to the mixing of ortho and para hydrogen which is a consequence of nuclear spin is included in the total entropy since this results in correct equilibrium constants based upon third law calculations. Differences in the values of R and C_p were found to have a negligible effect upon the functions.

Similar calculations with a different method of estimating the higher rotational levels by H. L. Johnston, L. G. Savodoff, and J. Belzer, Technical Report No. 2, Project R.P-316, Ohio State Univ. (1949), result in functions that are 0.5% lower above 5000°K.

For details concerning the dissociation energy see the monatomic hydrogen sheet.

$\sigma = 2$

Heat of Formation.

See KOH(g) table for details.

Heat Capacity and Entropy.

S. H. Bauer, R. H. Diner and R. F. Porter, J. Chem. Phys. 29, 991 (1958), have proposed a model for the dimeric alkali hydroxide (g) which consists of a square planar configuration for the alkali and oxygen atoms, with two hydrogen bridges between the oxygens (the hydrogen and oxygen atoms formed a rhombus perpendicular to the alkali-oxygen plane). R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. 31, 830 (1959), have suggested a square planar model without hydrogen bonding with alkali-oxygen bond distances 0.2 Å larger than those assumed for the monomeric alkali hydroxides. J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have also postulated a model for $\text{Li}_2(\text{OH})_2(\text{g})$ which consists of a trans configuration with hydrogens above and below the plane of the rhombus, and the bond angle O-Li-O = 100°. The last one was adopted for the molecular configuration of $\text{K}_2(\text{OH})_2$, but the bond angle O-K-O was modified to 90° (i.e. a square planar configuration for potassium and oxygen atoms). The bond angle K-O-H in $\text{K}_2(\text{OH})_2(\text{g})$ was assumed to be 110°. The bond distance K-O in $\text{K}_2(\text{OH})_2(\text{g})$ was estimated 10% longer than that in KOH(g). The bond distance O-H was estimated to be the same in $\text{H}_2\text{O}(\text{g})$. The three principal moments of inertia are $I_A = [17.5202] \times 10^{-39}$, $I_B = [38.5534] \times 10^{-39}$ and $I_C = [55.6452] \times 10^{-39} \text{ g. cm.}^2$

The first six selected vibrational frequencies were taken to be equal to those for $\text{K}_2\text{P}_2(\text{g})$ (see $\text{K}_2\text{P}_2(\text{g})$ table), and the rest were O-H stretching and bending frequencies which have been suggested by Berkowitz et al., loc. cit.

Heat of Formation.

J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. **35**, 533 (1960), have studied the Li₂O(c)-H₂O(g) equilibrium by the mass-spectrometric method. Using the reported equilibrium constants in the temperature range from 1100° to 1450° K. the heat of reaction Li₂OH₂(g) → 2LiOH(g) at 298° has been calculated by the second law and the third law methods as 63.2 and 63.7 kcal. mole⁻¹, respectively. (The third law drift is 0.5 ± 1.5 e.u.) Combination of the third law value (ΔH_f⁰ 298 = 63.7 kcal. mole⁻¹) with the heat of formation of lithium hydroxide (g) (ΔH_f⁰ 298 = -58.8 kcal. mole⁻¹) gives the heat of formation of dimeric lithium hydroxide (g) (ΔH_f⁰ 298 = -181.4 kcal. mole⁻¹) which has been adopted in the tabulation.

J. B. Berkowitz-Mattuck and A. Buchler, J. Phys. Chem. **67**, 1386 (1963), have also studied the Li₂O(c)-H₂O(g) equilibrium by the transpiration method, and reported two equilibrium constants (K₁₀₉₅° = 0.105 and K₁₁₄₅° = 0.357) for the reaction Li₂O(c) + H₂O(g) → Li₂OH₂(g). Using the third law method, the heat of reaction has been calculated from the equilibrium constants as 12.7 kcal. mole⁻¹ at 298.15° K. The heat of formation of Li₂(OH)₂(g) can be derived as ΔH_f⁰ 298 = -188.2 ± 3.5 kcal. mole⁻¹ which is different from the adopted value of Berkowitz, Meschi and Chupka, loc. cit. Berkowitz-Mattuck and Buchler attempted to explain the difference by inferring that the solid-gas equilibrium was not properly established in the measurement of Berkowitz, Meschi and Chupka, however, the absence of drift in the third law analysis does not support this conclusion.

Heat Capacity and Entropy.

S. H. Bauer, R. M. Diner and R. P. Porter, J. Chem. Phys. **29**, 991 (1958), have proposed a model for the dimeric alkali hydroxide (g) which consists of a square planar configuration for the alkali and oxygen atoms, with two hydrogen bridges between the oxygens (the hydrogen and oxygen atoms formed a rhombus perpendicular to the alkali-oxygen plane). R. C. Schoonmaker and R. P. Porter, J. Chem. Phys. **31**, 830 (1959), have suggested a square planer model without hydrogen bonding with alkali-oxygen bond distances 0.2 Å larger than those assumed for the monomeric alkali hydroxides. J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. **33**, 533 (1960), have also postulated a model for Li₂(OH)₂(g) which consists of a trans configuration with hydrogens above and below the plane of the rhombus, and the bond angle O-Li-O = 100°. The last one was adopted for the molecular configuration of Li₂(OH)₂(g), but the bond angle O-Li-O was modified to 90° (i.e. a square planar configuration for lithium and oxygen atoms). This bond angle Li-O-H in Li₂(OH)₂(g) was assumed to be 110°. The bond distance Li-O in Li₂(OH)₂(g) was estimated 10% longer than that in LiOH(g). The bond distance O-H was estimated to be the same in H₂O(g). The three principal moments of inertia are: I_A = [9.445] X 10⁻³⁹, I_B = [3.789] X 10⁻³⁹ and I_C = [12.803] X 10⁻³⁹ g. cm.²

The first six selected vibrational frequencies were taken to be equal to those for Li₂P₂(g) (see Li₂P₂(g) table) and the rest were O-H stretching and bending frequencies.

MAGNESIUM DIHYDRIDE (MgH₂) (CRYSTAL)

MOL. WT. = 26.336

ΔH_f^o 0 = -16.3 ± 2.2 kcal. mole⁻¹
 ΔH_f^o 298.15 = -18.2 ± 2.2 kcal. mole⁻¹
 S_{298.15}^o = 7.43 ± 0.20 cal. deg.⁻¹ mole⁻¹
 T_d = [560]°K.

Heat of Formation.

The heat of hydrolysis of MgH₂(c) was measured by O. C. Sinke and D. R. Stull, Thermal Laboratory, The Dow Chemical Company, private communication, July, 1956. The value of ΔH_f^o 298.15 was calculated to be -19.1 ± 2 kcal. mole⁻¹. From the decomposition pressure measurements for MgH₂(c) reported by F. H. Ellinger, et al., J. Am. Chem. Soc. 77, 2647 (1955) and J. F. Stampfer, Jr., C. E. Holley, Jr. and J. F. Suttle, J. Am. Chem. Soc. 82, 3504 (1960), the values of ΔH_f^o 298.15 for MgH₂(c) were found to be -17.9 ± 1.0 and -17.7 kcal. mole⁻¹, respectively. The value used was the average of these three.

Heat Capacity and Entropy.

The low temperature heat capacities (25-300°K.) was measured by O. C. Sinke and D. L. Hildenbrand, Thermal Laboratory, The Dow Chemical Company, private communication, February 1958. Above 300°K. the C_p values were estimated by comparison with those for MgF₂(c). S_{298.15} was obtained from O. C. Sinke and D. L. Hildenbrand, loc. cit., using S₂₅^o (extrap.) = 0.037 cal. deg.⁻¹ mole⁻¹.

Temperatures of Decomposition.

T_d was estimated from the value of ΔF_f^o in the table.

MAGNESIUM DIHYDROXIDE (Mg(OH)₂)

(CRYSTAL)

OPW = 58.32674

ΔH_f^o = -218.43 ± 0.5 kcal/mol
 ΔH_f^o = -218.43 ± 0.5 kcal/mol
 ΔH_f^o = -218.43 ± 0.5 kcal/mol
 S_{298.15}^o = 15.10 gibbs/mol
 T_d = [541]°K

Heat of Formation.

The adopted value is an average of -221.10 and -220.85 kcal/mol obtained from ΔH_f^o = 9.08 and 8.84 kcal/mol for the dehydration reaction Mg(OH)₂(c) = MgO(c) + H₂O(l). The two values correspond to naturally occurring brucite and to synthetic Mg(OH)₂ prepared from MgO by hydration at 177°C under a steam pressure of about 9 atm. The enthalpies of reaction are derived from studies of Taylor and Wells on the heats of solution of various samples of Mg(OH)₂ and MgO in aqueous HCl. These studies show that the heat of dehydration is quite dependent on the nature of the MgO sample; e.g., values for synthetic Mg(OH)₂ vary monotonically from 9.79 to 8.84 kcal/mol for MgO ignited at temperatures from 450 to 1425°C, respectively. The authors ascribe this difference primarily to increase in particle size at the higher ignition temperatures. We have adopted the results at 1425°C, since they are reasonably consistent with the high temperature samples on which the JANAF heat of formation for MgO is based. The uncertainty is estimated as ± 0.5 kcal/mol.

Shomate and Huffman have confirmed the heat of solution of MgO (ignited at 1000°C) within about 0.3 kcal. Their value may be combined with the heat of solution for synthetic Mg(OH)₂, determined under similar conditions by Torgeson and Sahaia, to obtain ΔH_f^o = 8.85 kcal/mol for the dehydration reaction. At the other extreme, the heat of solution data of Olauque and Archibald lead to ΔH_f^o = 9.74 kcal/mol; however, this value corresponds to MgO ignited at 350°C. The MgO sample was microcrystalline and had significant excess Cp, as suggested by Olauque and Archibald and later confirmed by data of T. H. K. Barron et al., Proc. Roy. Soc. (London) A250, 70 (1959). Olauque and Archibald intentionally used the microcrystalline form which would be similar to the product in their decomposition pressure measurements (190 and 212°C). Thus, it is not surprising that third law analysis of their decomposition pressures yields essentially the same heat of formation as their solution data (see summary below). Decomposition data at higher pressures have been reported by W. S. Pyfe, Am. J. Sci. 256, 729 (1958); D. M. Roy and R. Roy, ibid. 255, 573 (1957); O. C. Kennedy, ibid. 254, 567 (1956); O. M. Zhabrova and B. M. Kadenatzi, J. Gen. Chem. USSR (Eng. Transl.) 23, 1129 (1954); and L. O. Berg and I. S. Rassonskaya, Dokl. Akad. Nauk SSSR 81, 855 (1951). These data do not significantly affect the heat of formation, however, because of uncertainties in the attainment of equilibrium and in reduction to standard state values.

Heat Capacity and Entropy.

Low temperature heat capacities are from the data (22-321°K) of Olauque and Archibald, loc. cit., who used a synthetic, microcrystalline sample prepared by reaction of KOH with aqueous MgCl₂ at 210°C. The entropy is derived from the heat capacities using S₂₉₈^o = 0.027 eu. Above 321°K the heat capacities are extrapolated graphically. Enthalpy data (393-667°K) reported by P. N. Lashchenko and D. I. Kompanski, Zh. Prikl. Khim. 9, 628 (1935), were stated to be based on a calorimeter temperature close to room temperature. Within this uncertainty and the experimental scatter of about ± 5%, the enthalpy data are consistent with the selected values.

Temperature of Decomposition.

T_d is calculated as the temperature at which ΔG_r^o = 0 for Mg(OH)₂(c) = MgO(c) + H₂O(g).

Bond Distances: Mg-O = [1.80] Å

O-H = [1.07] Å

Bond Angles: Mg-O-H = [105°]

O-Mg-O = [180°]

Product of the Moments of Inertia: I_AI_BI_C = [95.6929] x 10⁻¹¹⁷ g cm

σ = [2]

Heat of Formation

Vapor densities of magnesium-bearing species over magnesium oxide were determined, using the transpiration method, by C. A. Alexander, J. S. Ogden and A. Levy, J. Chem. Phys. **32**, 3057 (1963). The MgO reacted with water vapor present in the carrier gas to form a gaseous product, presumably Mg(OH)₂. The authors eliminated MgOH and other species requiring the formation of gaseous oxygen as a likely product by holding constant the partial pressure of water but varying the ratio of oxygen and argon in the carrier gas. Experiments with different partial pressures of water indicated that each mole of water produced an equivalent number of moles of product in the vapor. This eliminates [Mg(OH)₂]₂ as a possible product, but not, for example, (MgO)₂H₂O. Species of the latter type are quite unlikely with magnesium, so the reaction is considered to be MgO(c) + H₂O(g) = Mg(OH)₂(g). Equilibrium data (1853-2020°K) given graphically by Alexander et al. yield ΔH_f^{o = 67.6 ± 1.9 kcal/mol by second law analysis and ΔH_f^{o = 65.2 kcal/mol with a drift of -1.5 ± 1 eu by third law analysis.}}

Heat Capacity and Entropy

The infrared spectra of Mg(OH)₂(c) were observed in the region 365-3700 cm⁻¹ by C. Cabannes-Ott, Ann. Chim. (Paris) **5**, 903-60 (1960). The vibrational frequencies of the gas are estimated by comparison with those for Mg(OH)₂(c), H₂O(g), H₂O₂(g), MgO(g) and MgF₂(g), and are adjusted to give reasonable agreement between the second and third law heats of reaction. The bond distances are estimated by comparison with those of MgF₂(g), MgO(g) and H₂O(g). The O-Mg-O angle is assumed to be 180°, while the Mg-O-H angle is assumed to be the same as that in H₂O(g). The three principal moments of inertia are I_A = 2.713 x 10⁻⁴⁰, I_B = 18.6455 x 10⁻³⁹ and I_C = 18.9168 x 10⁻³⁹ g cm².

(IDEAL GAS)

MOLYBDIC ACID (H_2MoO_4)

 Product of the Moments of Inertia: $I_{AB}^2 C = [1.5399 \times 10^{-113}] \text{ g cm}^6$ $\sigma = [2]$

Heat of Formation

The enhanced volatility of metallic molybdenum and molybdenum trioxide in the presence of water vapor at high temperatures has been investigated by several workers (1, 2, 3) using transpiration techniques. Glemser and Haeseler (1) and Buitten (2) have shown that the major volatilization reaction of the oxide is:

For the reaction of metallic molybdenum with water vapor, Belton and Jordan (3) reported the existence of $\text{MoO}_3(\text{OH})_2(\text{g})$ according to the equilibrium:

Second and third law analyses of these equilibrium data are summarized below.

Investigator	Reaction	Range, °K	No. of Points	$\Delta H^\circ_{298}(\text{kcal/mol})$	$\Delta H^\circ_{298}(\text{kcal/mol})$	Drift
Glemser and Haeseler (1)	A	873-983	Equation	38.2	31.9±0.3	-4.2
Buitten (2)	A	673-773	Equation	30.0	32.2±0.3	3.6
Belton and Jordan (3)	B	1473-1773	Equation	30.1	28.6±0.1	-0.1
* Third law values						

The adopted value, $\Delta H^\circ_f(\text{MoO}_3(\text{OH})_2, \text{g}) = -203.4 \pm 1.0 \text{ kcal/mol}$, is an average of these three results.

Heat Capacity and Entropy

The assumed tetrahedral structure for $\text{MoO}_3(\text{OH})_2$ is from Jordan (4). The O-H bond length and H-O-Mo bond angle are assumed to be the same as for $\text{H}_2\text{O}(\text{g})$. The Mo-O bond length is from the compilation of Sutton (5) and assumed to be the same as for Ag_2MoO_4 . Individual moments of inertia are $I_A = 23.782 \times 10^{-39}$, $I_B = 25.415 \times 10^{-39}$, and $I_C = 25.478 \times 10^{-39} \text{ g cm}^2$.

The vibrational frequencies are estimated by comparison with those for $\text{H}_2\text{SO}_4(\text{g})$ (6, 7) and are adjusted to give $S^\circ(\text{MoO}_3(\text{OH})_2, \text{g}) = 137.4 \text{ gibbs/mol}$ at 1600°K. This entropy value is derived from a second law analysis of the equilibrium data for reaction B reported by Belton and Jordan (3).

1499 (1)
3220 (1)

Bond Distance: N-H = 1.024 Å

Bond Angle: H-N-H = 103°

Product of the Moments of Inertia: I_AI_BI_C = 8.5 X 10⁻¹²⁰ g.³ cm.⁶

σ = 2

Heat of Formation.

The heat of formation of amidogen at 298.15°K., ΔH_f⁰ (NH₂, g) = 39.8 kcal. mole⁻¹ was obtained from the pyrolysis of N₂H₄ by J. A. Kerr, R. C. Sekhar and A. P. Trotman-Dickenson, J. Chem. Soc. 3217 (1953). They have reinvestigated the rate constants of the thermal decomposition N₂H₄ → 2NH₂ at different temperatures using the same techniques as M. Szwarc, J. Chem. Phys. 17, 505 (1949), and revised the activation energy to 57.1 kcal. mole⁻¹ for the reaction at 874°K. (instead of 60 kcal. mole⁻¹ at 1000°K. reported by Szwarc). The activation energy was assumed to be the same as the dissociation energy of the N-N bond in hydrazine. Using all JANAP auxiliary data, one obtains D₀ (H₂N-NH₂) = 55.4 ± 3 kcal. mole⁻¹ and ΔH_f⁰ 298 (NH₂, g) = 40.1 ± 3 kcal. mole⁻¹.

P. M. Page, Trans. Faraday Soc. 57, 1254 (1961), has measured the electron affinity of NH₂ and has applied the results to calculate the dissociation energy, D₀ (H-NH₂) = 102 ± 3 kcal. mole⁻¹. This value leads to the heat of formation ΔH_f⁰ 298 (NH₂, g) = 40.4 ± 3 kcal. mole⁻¹ which is in good agreement with the value selected. E. R. Lippincott and M. O. Dayhoff, Spectrochim. Acta, 15, 807 (1960) calculated theoretically the dissociation energy D₀ (H₂N-NH₂) = 59 kcal. mole⁻¹ which gives ΔH_f⁰ 298 (NH₂, g) = 41.9 kcal. mole⁻¹.

Heat Capacity and Entropy.

The bond distance and angle were measured from the electronic absorption spectra of NH₂ by K. Dressler and D. A. Ramey, Phil. Trans. Roy. Soc. London Ser. A 251, 553 (1959). The three principal moments of inertia are I_A = 0.1189 X 10⁻³⁹ g. cm.², I_B = 0.2149 X 10⁻³⁹ g. cm.² and I_C = 0.3338 X 10⁻³⁹ g. cm.²

The selected vibrational frequencies were obtained from the infrared spectrum of NH₂ by matrix isolation by D. E. Milligan and M. E. Jacox, J. Chem. Phys. 43, 4487 (1965). K. N. Tanner and R. L. King, Nature 181, 953 (1958) have also determined the vibrational frequencies ω₁ = 3200 cm.⁻¹ and ω₃ = 3280 cm.⁻¹ by flash photolysis and calculated ω₂ = 1060 cm.⁻¹. The symmetric and the enthalpy stretching frequencies are in good agreement. M. Taubol, Spectrochim. Acta 15, 505 (1960), has observed NH₂ bending frequencies, 1572 cm.⁻¹, 1619 cm.⁻¹ and 1623 cm.⁻¹, in HCONH₂(g), C₆H₅NH₂(g) and CH₃NH₂(g), respectively. In light of these observations and the adopted ω₂, Tanner and King's bending frequency seems to be in error.

(Ideal Gas) Mol. wt. = 30.02934

Bond Distance: N-H = [1.014] Å N-N = [1.23] Å

Bond Angle: H-N-N = [100]°

Product of the Moments of Inertia: I_AI_BI_C = [1.3968] X 10⁻¹¹⁷ g.³ cm.⁶

Heat of Formation.

The standard enthalpy of formation, ΔH_f⁰ 298 (N₂H₂) = 50.9 kcal. mole⁻¹, was calculated from the appearance and ionization potentials of di-imide reported by S. N. Poner and R. L. Hudson, J. Chem. Phys. 29, 442 (1958), using the JANAF ΔH_f⁰ (N₂H₂) = 26.1 kcal. mole⁻¹ in calculation. For example:

From the above heat of formation and that for NH₃ in the JANAF Tables 12-31-65, one can calculate a N-N bond energy of 109.4 ± 5 kcal. mole⁻¹ at 0°K. This is in agreement with the N-N bond in molecules such as N₂P₂.

Heat Capacity and Entropy.

The bond distances and angle were obtained from a quantum-mechanical calculation by W. Wheland and P. S. K. Chen, J. Chem. Phys. 24, 67 (1956). The three principal moments of inertia are I_A = [0.3116] X 10⁻³⁹, I_B = [1.9666] X 10⁻³⁹ and I_C = [2.2802] X 10⁻³⁹ g. cm.²

Since there are 12 valency electrons in N₂H₂, A. D. Walsh, J. Chem. Soc. 2268 (1953), has predicted a bent ground state, existing in either a cis or a trans configuration for diimide. E. J. Blau and B. P. Hochheimer, J. Chem. Phys. 41, 1174 (1964), have measured the infrared spectrum of diimide which was frozen in a cold trap as one of the decomposition products of N₂H₄. The spectrum of the solid N₂H₂ at liquid nitrogen temperature agrees with the predicted non-linear planar structure, and the molecule N₂H₂ appears mainly in cis form. They have also assigned six fundamental vibrational frequencies for cis N₂H₂(s) which have been adopted here for gaseous cis N₂H₂. Blau and Hochheimer also observed two gas phase bands (1277 - 1314 and 3050 - 3190 cm.⁻¹). K. Rosenkranz and G. C. Pimentel, J. Chem. Phys. 43, 507 (1965), have observed these bands in matrix isolation studies. They assigned ω₁ or ω₄ = 3074 cm.⁻¹ and ω₃ = 1279 cm.⁻¹ which are in satisfactory agreement with the selected frequencies.

Sodium Hydroxide, Dimeric (Na₂O₂H₂)

Heat Capacity and Entropy.

S. H. Bauer, R. H. Diner and R. P. Porter, J. Chem. Phys. 29, 921 (1958), have proposed a model for the dimeric alkali hydroxide (g) which consists of a square planar configuration for the alkali and oxygen atoms, with two hydrogen bridges between the oxygens (the hydrogen and oxygen atoms formed a rhombus perpendicular to the alkali-oxygen plane). R. C. Schoonmaker and R. P. Porter, J. Chem. Phys. 31, 830 (1959), have suggested a square planar model without hydrogen bonding with alkali-oxygen bond distances 0.2 Å larger than those assumed for the monomeric alkali hydroxides. J. Berkowitz, D. J. Meech and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have also postulated a model for Li₂(OH)₂(g) which consists of a trans configuration with hydrogens above and below the plane of the rhombus, and the angle O-H-O = 100°. The last one was adopted for the molecular configuration of Na₂(OH)₂, but the bond angle O-H-O in Na₂(OH)₂(g) was modified to 90° (i.e., a square planar configuration for sodium and oxygen atoms). The bond angle Na-O-H in Na₂(OH)₂(g) was assumed to be 110°. The bond distance O-H was estimated to be the same in H₂O(g). The three principal moments of inertia are $I_A = [14.0831] \times 10^{-39}$, $I_B = [18.1878] \times 10^{-39}$ and $I_C = [31.8449] \times 10^{-39} \text{ g. cm.}^2$

The first six selected vibrational frequencies were taken to be equal to those for Na₂F₂(g) (see Na₂F₂(g) table), and the rest were O-H stretching and bending frequencies which have been suggested by Berkowitz et al., loc. cit.

Heat of Formation

Taken from National Bureau of Standards Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952.

Heat Capacity and Entropy

A. S. Friedman and L. Haar, J. Chem. Phys. **22**, 2051 (1954), using the infra-red spectra analysis of W. S. Benedict, H. H. Claassen and J. H. Shaw, J. Research Natl. Bur. Standards **49**, 91 (1952), have calculated the thermodynamic functions for water including the anharmonic corrections. Friedman and Haar in comparing their calculation to that of a direct summation by Glatt, Adams, and Johnston, Ohio State University Res. Foundation Tech. Report No. 316-8 (1953), found that the difference between the two calculations was less than the uncertainty in the direct summation.

C_p values from 100° to 5000°K. are from Friedman and Haar. C_p from 5000° to 6000°K was extrapolated linearly. Using the tabulated functions of Friedman and Haar C_p , S , and $H_p - H_0$ at $T = 298.15^\circ\text{K.}$ was calculated by the method of Lagrangian curvilinear interpolation, W. J. Taylor, J. Research Natl. Bur. Standards **35**, 151 (1945).

The bond length and angle were obtained from a compilation by L. E. Sutton, "Tables of Interatomic Distances and Configurations in Molecules and Ions," The Chem. Soc., Burlington House, London W1, 1958.

SULFURIC ACID (H₂SO₄)

(LIQUID)

OFW = 98.07754

$$\Delta H_f^{\circ} 298.15 = -194.548 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 2.56 \text{ kcal/mol}$$

$$\Delta H_v^{\circ} = [13.35] \text{ kcal/mol}$$

$$S^{\circ} 298.15 = 37.501 \text{ gibbs/mol}$$

$$T_m = 283.53^{\circ}\text{K}$$

$$T_b = [608.6]^{\circ}\text{K}$$

Heat of Formation.

The heat of combustion (ΔH_c°) of rhombic sulfur (c) to H₂SO₄(aq), i.e. S(c, rhombic) + 3/2 O₂(g) + H₂O(l) = H₂SO₄(aq), has been determined by many investigators. Based on the reported ΔH_c° data, values of $\Delta H_f^{\circ} 298$ (H₂SO₄(l)) are derived using heats of solution and dilution for H₂SO₄(l), taken from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Technical Note 270-1, Natl. Bur. Std., 1965. The results obtained are presented in the table below. The value of $\Delta H_f^{\circ} 298$ (H₂SO₄(l)) is adopted as -194.548 ± 0.10 kcal/mol, which is the same as that given by Technical Note 270-1, loc. cit.

Investigator	Product	ΔH_c° , kcal/mol	$\Delta H_f^{\circ} 298$, kcal/mol
1. McCullough et al. (1963)	H ₂ SO ₄ (70H ₂ O)	-143.58 ± 0.09	-194.400
2. Scott et al. (1956)	H ₂ SO ₄ (75H ₂ O)	-143.98 ± 0.22	-194.775
3. Good et al. (1960)	H ₂ SO ₄ (115H ₂ O)	-143.85 ± 0.06	-194.521
4. Manason and Sumner (1963)	H ₂ SO ₄ (115H ₂ O)	-143.93 ± 0.07	-194.601

- D. W. Scott, J. P. McCullough, W. N. Hubbard, J. F. Measerly, I. A. Hoesenlopp, F. R. Frow and G. Waddington, J. Am. Chem. Soc. **78**, 5463 (1956).
- J. D. Good, J. L. Lachina and J. P. McCullough, J. Am. Chem. Soc. **82**, 5589 (1960).
- M. Manason and S. Sumner, Acta Chem. Scand. **17**, 723 (1963).

Heat Capacity and Entropy.

The heat capacities, 283.46 to 300°K, were measured by W. P. Olague, E. W. Hornung, J. E. Kunzler, and R. R. Rubin, J. Am. Chem. Soc. **82**, 62 (1960). The Cp values above 300°K are obtained from graphical extrapolation. The value of S°₂₉₈ was reported by Olague, Hornung, Kunzler and Rubin, loc. cit., based on low temperature heat capacity measurements of H₂SO₄(c).

Melting Data.

T_m and ΔH_m° are taken from T. R. Rubin and W. P. Olague, J. Am. Chem. Soc. **74**, 800 (1952). The value, T_m=283.53°K, has been reported by C. M. Gable, H. F. Betz and S. H. Maron, J. Am. Chem. Soc. **72**, 1445 (1950), as well as J. E. Kunzler and W. P. Olague, J. Am. Chem. Soc. **74**, 797 (1952). The heat of melting (ΔH_m°) has also been determined by the following investigators:

ΔH_m° , kcal/mol	Source
2.35	Pickering, Proc. Roy. Soc. (London) 49 , 11 (1891).
2.25	Hantzsch, Z. Physik. Chem. 61 , 262 (1907).
2.24	Knietsch, quoted by Hantzsch, loc. cit.
2.55	Brönsted, Z. Physik. Chem. 68 , 693 (1910).
2.56	Rubin and Olague, J. Am. Chem. Soc. 74 , 800 (1952).

Vaporization Data.

T_b is the temperature at which the Gibbs energy change (ΔG_v°) for the reaction H₂SO₄(l) = H₂SO₄(g) approaches zero. The difference between ΔH_f° for H₂SO₄(g) and H₂SO₄(l) at T_b is ΔH_v° . According to O. P. Luchinskii, Zh. Fiz. Khim. **30**, 1207 (1956), the total vapor pressure over H₂SO₄(l) reaches one atmosphere at 553°K with a vapor composition of 76.6 mole percent SO₃, 22.6% H₂SO₄, and 0.8% H₂O. This composition implies that the real liquid phase enhances the vapor decomposition by reducing the partial pressure of water vapor.

Heat of Formation

The vapor phase equilibria of the H₂SO₄, H₂O and SO₃ system have been studied by (1) E. Rodenstein and M. Katayama, Z. Elektrochem. 15, 244 (1909), Z. Physik. Chem. 69, 26 (1909); (2) G. P. Luchinskii, Zh. Fiz. Khim. 30, 1207 (1956), and (3) A. V. Suvorov, R. B. Dobrovin and S. M. Gaidarov, Russ. J. Inorg. Chem. (English Transl.) 10, 710 (1955). The data of Rodenstein and Katayama and of Suvorov et al. were obtained from PVT studies, while those of Luchinskii were based on vapor pressure measurements. A translation of Luchinskii's paper is not yet available, so it is not known whether he obtained the vapor composition experimentally or by calculation. Using the reported equilibrium values for the reaction H₂SO₄(g) = H₂O(g) + SO₃(g), we evaluate the corresponding enthalpy changes by both the second and third law methods. The results are presented in the table below. The value of H°₂₉₈ for H₂SO₄(g) is adopted as -177 ± 2 kcal/mol.

Investigator	Temp., °K	No. of Points	Second Law	Third Law	Drift
1. Rodenstein & Katayama (1909)	586-756.2	53	-22.95 ± 0.66	-24.55	-2.3 ± 1.0
2. Luchinskii (1956)	333.2-473.2	8	-24.02 ± 0.22	-24.43	-1.2 ± 0.5
3. Suvorov (1965)	583.0-713.0	40	-27.14 ± 0.45	-24.90	+3.3 ± 0.6

*Calculation based on the third law ΔH°₂₉₈ value.

Heat Capacity and Entropy

The molecular structure and bond angles (O-S-O, HO-S-OH) are estimated by comparison with those for SF₂O₂(g) reported by D. R. Lide, D. E. Mann and R. M. Fristrom, J. Chem. Phys. 26, 734 (1957). The S-O and S-OH bond distances are assumed to be the same as those in H₂SO₄(c), determined by R. Pascard, Compt. Rend. 240, 2162 (1955). The OH distance and S-O-H angle are taken from those for H₂O(g). Electric deflection studies by A. Behler, J. L. Stauffer and K. Klemperer, J. Chem. Phys. 45, 605 (1967), indicate that H₂SO₄(g) is polar, which is consistent with the assumed C_{2v} structure.

The infrared absorption spectrum in the range 4000 to 400 cm⁻¹ of normal and deuterated H₂SO₄(g) above H₂SO₄(l) was observed by S. M. Chackalackal and P. R. Starford, J. Am. Chem. Soc. 88, 723 (1966). The authors assigned nine vibrational frequencies, which are adopted here. The three principal moments of inertia are: I_A = 1.570 x 10⁻³⁸, I_B = 1.586 x 10⁻³⁸, and I_C = 1.702 x 10⁻³⁸ g cm².

Four of the six missing frequencies are obtained from P. A. Giguère and R. Savoie, J. Am. Chem. Soc. 85, 287 (1963), which were estimated by comparison with infrared frequencies for the crystal and Raman values for the liquid. The remaining two frequencies, ν₇ = 450 and ν₁₄ = 450 cm⁻¹, are assigned arbitrarily so that the second and third law values for ΔH°_{298.15} derived from equilibrium data are in reasonable agreement.

Td = [393]°K

Heat of Formation

V. I. Spitsyn and N. N. Patsukova¹ have measured calorimetrically the heats of reaction (1) and (2) at 298°K as -13.80 ± 0.01 and -13.05 ± 0.02 kcal/mol, respectively. The reactions are given as follows:

Combination of reactions (1) and (2) gives ΔH₂₉₈^c = -0.75 ± 0.04 kcal/mol for WO₃(c) + H₂O(l) → H₂WO₄(c), which leads to ΔH₂₉₈^c(H₂WO₄, c) = -270.5 ± 0.4 kcal/mol.

To obtain WO₃(c) in a form soluble in the calorimetric solution, Spitsyn and Patsukova dehydrated H₂WO₄(c) at the relatively low temperature of 250°C. The resulting WO₃(c) was a very fine lemon-yellow powder which may have excess surface free energy compared with the JANAF standard state. The latter is WO₃ formed at high temperature in a calorimetric bomb. The actual heat of formation of tungstic acid should be less negative if this effect is significant.

The previously accepted value^{2,3,4} -280.2 ± 0.4 kcal/mol, was based on the pressure-temperature-composition studies of G. P. Huttig and B. Kurre⁵ for the WO₃-H₂O system. We suspect that the data do not correspond to equilibrium (see entropy section) for the reaction H₂WO₄(c) = WO₃(c) + H₂O(g).

Heat Capacity and Entropy

C_{p300} = 27.0 gibbs/mol is estimated using Kopp's rule. Since the decomposition temperature of H₂WO₄(c) is approximately 400°K, which is relatively low for hydrogen and oxygen to reach their maximum Cp contribution, we estimate Cp₄₀₀ = 31.0 gibbs/mol for H₂WO₄(c).

The entropy, S₂₉₈^b = 34.6 eu, is estimated so that the decomposition pressure of water is one atmosphere at 120°C. This value is quite uncertain as suggested by comparison with the following estimates. A lower limit may be obtained from S_{283.5}^b = 26.8 eu for H₂SO₄(c). Summation of the entropies for WO₃(c) and H₂O(c) [10.7 eu] yields 28.8 eu, an estimate which is somewhat larger than the lower limit. An upper limit may be obtained by assuming that the pressure of about 14 mm at 190°C corresponds to equilibrium for the reaction H₂WO₄(c) = WO₃(c) + H₂O(g). This pressure, based on the plateau in the temperature-composition data of Huttig and Kurre⁵, yields S₂₉₈^b = 46.5 eu when combined with the adopted ΔH₂₉₈^c and JANAF auxiliary data. Since the estimate appears to be unreasonably large, we suggest that this region of the curve may correspond to the reaction WO₃·0.5 H₂O(c) = WO₃(c) + 0.5 H₂O(g). In contrast, the observed pressures⁵ for samples having mole ratios (H₂O/WO₃) of 1.2 - 1.35 leads to S₂₉₈^b = 34 eu, if the reaction is WO₃·H₂O(c) = WO₃(c) + H₂O(g).

Temperature of Decomposition

Td is calculated as the temperature at which the Gibbs energy change of the reaction H₂WO₄(c) → WO₃(c) + H₂O(g) approaches zero.

Spitsyn and Patsukova¹ observed that some dehydration of stoichiometric H₂WO₄(c) occurs at temperatures as low as 90°C. Thermal studies^{6,7} on tungstic acid containing some excess water indicated the start of dehydration somewhere in the region of 60 - 120°C. These temperatures yield a lower limit for Td on the presumption that the experiments correspond to a partial pressure of water of less than one atmosphere.

Bond Distances: W-O = [1.81] Å

Bond Angle: O-W-O = [109.47]°

Product of the Moments of Inertia: I_AI_BI_C = [1.443 x 10⁻¹¹³] g³ cm⁶

Heat of Formation: ΔH_f²⁹⁸ = -216.5 ± 1.0 kcal/mol, is derived from equilibrium data^{1,2,3,4,5} obtained by the transpiration method. The data are in reasonable agreement and they are summarized below. Beilton and McCarron¹ have precedence that W₃H₂O is the species responsible for the increased volatilization of W(c) and W₃(c) in the presence of water vapor. Based on their data for W(c) and the earlier data for W₃(c), Beilton and McCarron ruled out the possibility of significant amounts of (W₃)₂H₂O and W₃,2 H₂O.

Heat of Formation.

The adopted heat of formation, ΔH_f²⁹⁸ = -216.5 ± 1.0 kcal/mol, is derived from equilibrium data^{1,2,3,4,5} obtained by the transpiration method. The data are in reasonable agreement and they are summarized below. Beilton and McCarron¹ have precedence that W₃H₂O is the species responsible for the increased volatilization of W(c) and W₃(c) in the presence of water vapor. Based on their data for W(c) and the earlier data for W₃(c), Beilton and McCarron ruled out the possibility of significant amounts of (W₃)₂H₂O and W₃,2 H₂O.

Investigator	Reaction*	Temp. (°K)	No. of Points	ΔH _f ²⁹⁸ (kcal/mol)	Drift (eu)	ΔH _f ²⁹⁸ (kcal/mol)
Beilton & McCarron ¹	A	1473-1773	Equation	14.70	14.63	-216.56

Heat Capacity and Entropy.

The vibrational frequencies are estimated by comparison with those for H₂SO₄(g) reported by P. A. Olgue and R. Savoie, J. Am. Chem. Soc. **85**, 287 (1963), and S. M. Chackalackal and P. B. Stafford, J. Am. Chem. Soc. **88**, 723 (1966). These frequencies are also adjusted so that S_{298.15} is 136.7 eu as reported by Beilton and McCarron, loc. cit. This entropy was derived from second law analysis of the equilibrium constants for reaction A.

The configuration of W₃ group is assumed to be tetrahedral. The bond angle W-O-H is estimated to be the same as the angle of H₂O(g). The bond distances are assumed to be the same as those in W₃(g) and H₂O(g). The three principal moments of inertia are I_A = 2.328 x 10⁻³⁸, I_B = 2.487 x 10⁻³⁸ and I_C = 2.493 x 10⁻³⁸ g cm².

PHOSPHORUS HYDRIDE (PH₂)

(IDEAL GAS)

MOL. WT. = 32.991

Point Group [C_{2v}] $\Delta H_f^o = [30.6 \pm 23] \text{ kcal. mole}^{-1}$ $S_{298.15}^o = [50.8] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^o 298.15 = [30.1 \pm 23] \text{ kcal. mole}^{-1}$

Ground State Multiplicity = [2]

Vibrational Frequencies and Degeneracies

 $\omega, \text{ cm.}^{-1}$

[2327] (1)

[1020] (1)

[2322] (1)

Bond Distances: P-H = [1.419] Å

Bond Angle: H-P-H = [93.7]°

Product of Moments of Inertia: $I_A I_B I_C = [6.95 \times 10^{-119}] \text{ g.}^3 \text{ cm.}^6$ $\sigma = 2$

Heat of Formation.

$\Delta H_f^o 298.15$ was estimated by V. N. Distefano, R. L. Potter, and S. N. Fox, "Thermodynamic Functions of Some Combustion Products Containing Phosphorus-I.", American Cyanamid Company. The $\Delta H_f^o 298.15$ was estimated by taking 63% of the dissociation energy of PH₂ and using it as the dissociation energy of PH₂. D. Wiles and C. Winkler, J. Phys. Chem. 61, 902 (1957) have estimated the $\Delta H_f^o 298.15$ for PH₂(g) to be 30 kcal. mole⁻¹.

Heat Capacity and Entropy.

The vibrational spectra of PH₂ from the flash photolysis of PH₃ has been reported by D. A. Ramsay, Nature 179, 375 (1956) and in N. Y. Acad. Sci. 61, 485, (1957). Similarities between the spectra of NH₂ and PH₂ were found. For NH₂ and NH₃ bond angles and bond distances were reported to be about the same. By analogy then the bond angles and bond distances of PH₂ and PH₃ should be nearly the same. The moments of inertia for PH₂ were therefore calculated from the molecular constants for PH₃. The principal moments were found to be $I_A = 3.587 \times 10^{-40} \text{ g. cm.}^2$, $I_B = 2.959 \times 10^{-40} \text{ g. cm.}^2$, and $I_C = 6.546 \text{ g. cm.}^2 \times 10^{-40}$.

Distefano and Potter (loc. cit.) have assumed the ground state degeneracy to be 2, because of the unpaired electron. The vibrational frequencies reported by Distefano and Potter (loc. cit.) have been used. They used a simple force field and the force constants of PH₃ to obtain the vibrational frequencies.

Heat of Formation.

The heat of formation of hydrogen sulfide has been calorimetrically measured by H. Zeumer and W. A. Roth, Z. Elektrochem. 40, 777 (1934), and A. P. Kapustinikii and R. T. Kankovskii, Zhur. Fiz. Khim. 32, 2810 (1958), as $\Delta H_f^o(298) = -4.80 \pm 0.15$ kcal. mole⁻¹ and $\Delta H_f^o(298) = -4.94 \pm 0.08$ kcal. mole⁻¹, respectively. A weighted average of these two values was taken for the standard enthalpy of formation of hydrogen sulfide.

Heat Capacity and Entropy.

The bond distance, angle and vibrational frequencies were obtained from H. C. Allen, Jr. and E. K. Plyler, J. Chem. Phys. 25, 1132 (1956).

J. S. Gordon, private communication, Feb. 7, 1961, has calculated C_p from 298 to 6000°K. by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes second order corrections for vibrational anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The correction constants were obtained from Allen and Plyler, loc. cit. Below 298°K. the rigid-rotator harmonic oscillator method was used to calculate the functions, but at 298°K. and above Gordon's thermodynamic functions were adopted in this tabulation.

TITANIUM DIHYDRIDE (TiH₂)

(CRYSTAL)

MOL. WT. = 49.916

$$\Delta H_f^0 = [-32.5 \pm 2.0] \text{ kcal. mole}^{-1}$$
$$\Delta H_f^{298.15} = [-34.5 \pm 2.0] \text{ kcal. mole}^{-1}$$
$$S_{298.15}^0 = 7.101 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

Heat of Formation.

The heat of combustion of TiH_{1.73}(c), the stable species of titanium hydride, was reported to be -247.8 kcal. by A. Sieverts and A. Götts, Z. anorg. allgem. Chem. 199, 394 (1931). From this data the value of ΔH_f⁰ 298.15 for TiH_{1.73}(c) was calculated to be -29.40 kcal. mole⁻¹. The heat of dissociation of titanium hydride having compositions between the rough limits TiH_{1.75}-TiH_{1.93} was given as 19.15 kcal. per mole of H₂ dissociated by T. R. P. Gibb, Jr., J. McSharry, and R. W. Bragdon, J. Am. Chem. Soc. 73, 1751 (1951). Assuming this value is applicable to compositions between the limits TiH_{1.73}-TiH₂, the difference in the heat of formation of titanium hydride between TiH_{1.73} and TiH₂ was estimated to be -5.17 kcal. mole⁻¹. Thus the value of ΔH_f⁰ 298.15 for TiH₂(c) was calculated.

Heat Capacity and Entropy.

The low temperature C_p for TiH_{1.97}(c), 24-363°K., were measured by B. Stalinski and Z. Bieganski, Bull. Acad. Polon. Sci., Ser. Sci. Chim., 8, No. 5, 243 (1960). This data were adopted for TiH₂(c) due to lack of the measured C_p values. A small but well marked λ-type anomaly with a maximal value of C_p at 298.5°K. in the C_p vs. T curve was observed. ΔS_{298.15} was reported by B. Stalinski and Z. Bieganski, loc. cit., based on S₂₉₈(extrap.) = 0.065 cal. deg.⁻¹ mole⁻¹.

Heat of Formation

A weighted average based on analysis using JANAF functions was selected. Haber, Tammaru and Oeholm, Z. Elektrochem. 21, 206 (1915) obtained $\Delta H_{298}^\circ = 11.10$ for NH₃ → 0.5 N₂ + 1.5 H₂ by flow calorimetry. Estimated uncertainty is 1% and the formation value was corrected by 0.025 kcal. for non-ideality of NH₃. Becker and Roth, *ibid.* 20, 836 (1934) measured ΔH_f° for NH₃(g) + H₂O(l) → NH₄OH(aq), ΔH_f° for NH₃(g) + H₂O(l) → NH₄OH(aq), and the necessary ΔH_{298}° for NH₃(g) → 0.5 N₂(g) + 1.5 H₂(g) from the equilibrium data of Larson and Dodge, J. Am. Chem. Soc. 45, 182.9 ± 0.24 for 3H₂O(l) + N₂(g) → 2NH₃(g). Equilibrium data from Larson and Dodge, J. Am. Chem. Soc. 45, 2918 (1923) and Haber, Tammaru and Ponnaz, Z. Elektrochem. 21, 89 (1915) were analyzed as tabulated by Stephenson and McMahon, J. Am. Chem. Soc. 61, 437 (1939) from the non-ideality corrections of Olliepie and Beattie, Phys. Rev. 35, 743 (1930). Data (1000-3000 atm) from Minchieser and Dodge, A.I.Ch.E. Journal 2, 431-6 (1956) were omitted because of uncertainty in non-ideality while data (1 atm) of Haber and Maschke, Z. Elektrochem. 21, 128 (1915) were assumed ideal. High-temperature calorimetry of the direct decomposition includes Haber and Tammaru, Z. Elektrochem. 21, 191 (1915) and Wittig and Schmetz, *ibid.* 63, 470 (1959).

*Third law values for equilibrium data are followed by second law values in parentheses.
 Heat Capacity and Entropy.

The functions are an approximation of the non-rigid rotator anharmonic oscillator based on calculations of Harrison and Kobe, Chem. Eng. Progr. 49, No. 7, 349 (1955) and Yungman, Olurich and Ritscheva, Trudy Gosudarst. Inst. Priklad. Khim. 49, 20 (1962). In these calculations anharmonicity of ν_2 associated with inversion doubling was treated by summation over the energy levels. Both calculations include rotational distortion corrections while Yungman, at el., also allow for anharmonicity and vibration-rotation interaction of the other fundamentals. JANAF functions agree with the results to within 0.02 e.u. in the range 298-1500°K.

Two sets of rigid rotator harmonic oscillator functions were also tested for consistency with the ammonia data (see below). These were obtained from molecular dimensions and either calculated zero order frequencies ($\bar{\nu}$) or observed wave numbers ($\bar{\nu}$) obtained by Benedict and Plyler, Can. J. Phys. 35, 1235 (1957) from high resolution infrared studies. Herzberg, "Infrared and Raman Spectra", pp. 503-4, 1945 states that $\bar{\nu}$ should be used and the RRHOY functions give better, but not perfect, agreement with the observed C_p for NH₃. Principal moments of inertia are I_A = 4.414 × 10⁻⁴⁰ end I_B = I_C = 2.809 × 10⁻⁴⁰ g. cm.². Electron diffraction studies by Bastiansen and Bagley, Acta Chem. Scand. 18, 2077 (1964) give slightly different constants (bond distance 1.015 Å and angle = 109.1°).

Bond Distance: H-O = [0.96] Å

Bond Angle: H-O-H = [109]°

Product of the Moments of Inertia: I_AI_BI_C = [2.39] X 10⁻¹¹⁹ g³ cm⁶

σ = 3

Heat of Formation.

The proton affinity of water has been measured by the ion impact method as -169 kcal/mol by V. L. Tal'rose and E. L. Frenkivitch, Doklady Akad. Nauk SSSR 111, 376 (1956), J. An. Chem. Soc. 80, 2344 (1958). The selected heat of formation of hydronium ion, ΔH_f^o(H₃O⁺, g) = 139.1 kcal/mol, was derived from the ΔH_f^o = -169 kcal/mol for H₂O(g) + H⁺(g) → H₃O⁺(g), using the JANAF ΔH_f^o(H₂O, g) = -57.1 and ΔH_f^o(H⁺, g) = 385.2 kcal/mol.

The values of 195 and 207 kcal/mol for the heat of formation of H₃O⁺(g) have also been reported by P. M. Field and J. L. Franklin, "Electron Impact Phenomena," Academic Press, New York, 1957, and R. R. Bernecker and F. A. Long, J. Phys. Chem. 65, 1565 (1961), respectively. These two values were based on the electron impact studies which may involve unaccounted excitations and excess energy in the fragments. Other literature values have been reviewed by D. M. Bishop, J. Chem. Phys. 43, 4453 (1965).

J. A. Green and T. M. Sugden, Ninth Symposium (International) on Combustion, Academic Press, New York, 1963, based on the studies of the positive ions in flames by mass spectrometry, prefer the value derived from the proton affinity of water obtained by Tal'rose and Frankvitch, rather than the electron impact data. From the approximate equilibrium constant calculations for the reaction HCO⁺(g) + H₂O(g) ⇌ H₃O⁺(g) + CO(g), D. G. Clifton, AD444078, G. M. Defense Research Laboratory, General Motors Corp., Santa Barbara, Calif., July 1964, has also found that the heat of formation of H₃O⁺(g) derived from the proton affinity of water, not from the electron impact data, leads to agreement with the experimental data given by Green and Sugden.

Heat Capacity and Entropy.

Since the molecule H₃O⁺(g) has the same number of valence electrons as NH₃(g), a pyramidal molecular configuration (C_{3v}) is assumed for H₃O⁺(g) in the tabulation. D. G. Clifton, J. Chem. Phys. 41, 3656 (1964), has obtained a bond distance O-H of 0.95 Å from an application of covalent bond radii and the effect of electric charge, and a bond angle H-O-H of 109° by extrapolating a plot of bond length versus bond angle for NH₃(g) and PH₃(g) to 0.95 Å. Both values are adopted in the tabulation. The three principal moments of inertia are I_A = 0.4004 X 10⁻³⁹, I_B = I_C = 0.2445 X 10⁻³⁹ g cm². D. M. Bishop, loc. cit., has calculated theoretically the bond distance H-O of 0.96 Å and the bond angle H-O-H of 114° 26' with a planar D_{3h} molecular configuration. The vibrational frequencies were calculated by the valence force method from the estimated stretching and bending force constants of Clifton.

ORTHOPHOSPHORIC ACID (H_3PO_4)
(CRYSTAL)
MOL. WT. = 97.999

$\Delta H_f^0 = -297.5 \pm 0.3 \text{ kcal. mole}^{-1}$
 $\Delta H_m^0 = 3.100 \text{ kcal. mole}^{-1}$
 $S_{298.15}^0 = 26.42 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 315.51^\circ \text{K}$

Heat of Formation.

The heat of formation was determined by W. S. Holmes [private communication July 5, 1962, Albright and Wilcoxon (MPG) Ltd., Oldbury, Birmingham, Great Britain (in press by Faraday Society)]. W. S. Holmes measured the enthalpy of combustion of white phosphorus (α form) in oxygen in a bomb calorimeter. The product, P_4O_{10} (hexagonal), was hydrolyzed in 10N perchloric acid to give H_3PO_4 . Measurement of the enthalpy of solution of $H_3PO_4(c)$ then enabled the ΔH_f^0 298.15 to be calculated according to the following cycle:

* All ΔH_f^0 's were measured.

E. P. Egan, Jr. and B. B. Luff, J. Phys. Chem., 65, 523 (1961), from partial molal heat contents of H_3PO_4 solutions found that a smooth extrapolation to 100% H_3PO_4 would give them a ΔH_f^0 298.15 for $H_3PO_4(c)$ which was 755 cal. mole⁻¹ greater than the ΔH_f^0 298.15 reported in the National Bureau of Standards Circular 500. The Circular 500 (loc. cit.) heat of formation refers to the work of Thomson, "Thermochemische Untersuchungen," Vol. 2, Barth, Leipzig (1882-1886). The heats of formation summarized:

ΔH_f^0 298.15	Source
-305.7 $\pm$ 0.3 kcal. mole ⁻¹	W. S. Holmes (loc. cit.)
-306.2 kcal. mole ⁻¹	Circular 500 (loc. cit.)
-305.4 kcal. mole ⁻¹	Egan and Luff (loc. cit.)
The selected ΔH_f^0 298.15, -305.7 $\pm$ 0.3 kcal. mole ⁻¹ , was corrected by +4.17 kcal. mole ⁻¹ , which is the ΔH_f^0 298.15 of white (α) phosphorus.	

Heat Capacity and Entropy.

Third law entropy was calculated from the low temperature heat capacities measured by E. P. Egan, Jr. and Z. T. Wakefield, J. Phys. Chem., 61, 1500 (1957).

Melting.

The heat of fusion, ΔH_m , was reported by E. P. Egan, Jr. and B. B. Luff, J. Phys. Chem., 65, 523 (1961) from ΔH_m data measured by E. P. Egan, Jr. and Z. T. Wakefield, J. Phys. Chem., 61, 1500 (1957). The melting point $T_m = 315.51^\circ \text{K}$ was taken from the work of W. H. Ross and R. M. Jones, J. Am. Chem. Soc., 47, 2165 (1925).

Orthophosphoric Acid (H₃PO₄) (Liquid)

Mol. Wt. = 97.999
ΔH_f° 298.15 = -298.81 ± 0.5 kcal. mole⁻¹
S° 298.15 = 35.0 cal. deg.⁻¹ mole⁻¹
T_m = 315.61°K
ΔH_m = 3.100 kcal. mole⁻¹

Heat of Formation. Calculated from ΔH_f° 298.15 for H₃PO₄(c) and ΔH_m given by E. P. Egan, Jr., and B. B. Luff, J. Phys. Chem. 65, 523 (1961) using the ΔH_m data reported by E. P. Egan, Jr., and Z. T. Wakefield, J. Phys. Chem. 61, 1500 (1957).

Heat Capacity and Entropy. The heat capacity is estimated. The entropy at 298.15°K. is calculated using S° 298.15 of H₃PO₄(c) and the ΔH_m at 298.15°K.

Melting Data. T_m reported by W. H. Ross and R. M. Jones, J. Am. Chem. Soc. 41, 2165 (1925). ΔH_m from E. P. Egan, Jr., and Z. T. Wakefield (loc. cit.).

Vibrational Levels and Multiplicities	ω, cm ⁻¹
2332.9 (1)	992 (1)
2327.7 (2)	1122.4 (2)

P-H distance 1.42 Å H-P-H angle = 93° 50' σ = 3

$$I_A = I_B = 6.29 \times 10^{-40} \text{ g cm}^2 \quad I_C = 7.24 \times 10^{-40} \text{ g cm}^2$$

Heat of Formation

The heat of formation was derived by S. R. Gunn and L. G. Green, J. Phys. Chem., **65**, 779 (1961). In order to obtain the ΔH_f° 298.15 they measured the heat of explosive decomposition of phosphine gas. There is a good deal of uncertainty about the heat of formation of PH₃(g), for instance:

$$\Delta H_f^{\circ} 298.15$$

$$+3.6 \text{ kcal mole}^{-1}$$

$$+6.3 \text{ kcal mole}^{-1}$$

$$-2.34 \text{ kcal mole}^{-1}$$

$$+1.6 \text{ kcal mole}^{-1}$$

Source

The heat of reaction between gaseous PH₃ and saturated bromine water. M. J. Ogier, Ann. Chim. Phys., **20**, 5 (1880).

The heat of combustion of PH₃(g) in O₂(g) to form H₃PO₄. M. P. Lemoult, Compt. Rend., **115**, 374 (1907).

Equilibrium data of W. N. Ipatiew, and A. W. Frost, Ber. dtsh. chem. Ges., **63B**, 1104 (1930). Their data showed a wide variation in ΔH , as much as 11 kcal mole⁻¹.

National Bureau of Standards, Report No. 7437, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element and Some Related Compounds," 1 January 1962 (page 80-91).

The heats of formation have been reviewed by T. L. Cottrell, "The Strength of Chemical Bonds," Butterworth's Scientific Publications, London, (1958); and by F. R. Bichowsky and F. D. Rossini, "The Thermochemistry of The Chemical Substances," Reinhold Publishing Corp., New York (1936).

The heat of formation selected was, $+1.3 \pm 0.4 \text{ kcal mole}^{-1}$, as reported by Gunn and Green (loc. cit.). The selected heat of formation was based on white (α) phosphorus and thus required an adjustment for the red (V) phosphorus reference state.

Heat Capacity and Entropy

The fundamental wave number and degeneracy assignments are from the infrared spectral data by V. N. McConaghie and H. H. Nielsen, J. Chem. Phys., **21**, 1836, (1953). The molecular constants are those obtained from infrared data by H. H. Nielsen, J. Chem. Phys., **20**, 759 (1952). Nielsen (loc. cit.) has reported the molecular constants after calculating the Coriolis coupling effect between the wave numbers 2 and 4, or (992 cm⁻¹) and (1122.4 cm⁻¹).

HYDRAZINE (N₂H₄)

(LIQUID)

MOL. WT. = 32.04528

$$S_{298.15} = 29.05 \pm 0.1 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 274.69^\circ\text{K.}$$

$$T_b = 386.9^\circ\text{K.}$$

$$\Delta H_f^\circ 298.15 = 12.10 \pm 0.1 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^\circ = 3.025 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^\circ = 9.70 \text{ kcal. mole}^{-1}$$

Heat of Formation.

A. M. Hughes, R. J. Corruccini and E. C. Ollbert, J. Am. Chem. Soc. **61**, 2639 (1939), measured the heats of combustion of hydrazine and hydrazine monohydrate. The data, adjusted as suggested by L. O. Cole and E. C. Ollbert, J. Am. Chem. Soc. **73**, 5423 (1951), are summarized below. Heats of solution determined by V. C. Bushnell, A. M. Hughes and E. C. Ollbert, J. Am. Chem. Soc. **59**, 2142 (1937) interrelate N₂H₄(l) and N₂H₄·H₂O(l). An intermediate value was selected from the resulting heats of formation.

Source	Reaction	ΔH _f ^o 298	ΔH _f ^o 298
Hughes	N ₂ H ₄ (l) + O ₂ (g) → N ₂ (g) + 2H ₂ O(l)	-148.68 ± 0.06	12.05
Hughea	N ₂ H ₄ ·H ₂ O(l) + O ₂ (g) → N ₂ (g) + 3H ₂ O(l)	-147.00 ± 0.06	—
Bushnell	N ₂ H ₄ (l) + H ₂ O(l) → N ₂ H ₄ ·H ₂ O(l)	-1.80	12.17*

*From combination of second and third reactions.

Heat Capacity and Entropy.

Heat capacities (12-340°K) of hydrazine crystal and liquid were determined by D. W. Scott, O. D. Oliver, M. E. Oras, W. M. Hubbard and H. M. Huffman, J. Am. Chem. Soc. **71**, 2293 (1949). Values beyond the experimental range for the liquid were extrapolated linearly. The entropy was obtained from the heat of melting and the smoothed heat capacities of the crystal using S₁₂^o = 0.023 cal. deg.⁻¹ mole⁻¹.

Melting Data.

Taken from Scott et al., loc. cit.

Vaporization Data.

The normal boiling point and heat of vaporization are those calculated for the ideal gas from these tables. The boiling point found for the real gas (397.3°K) by W. Hieber and A. Woerner, Z. Elektrochem. **40**, 252 (1934) is in good agreement. The selected heat of vaporization, ΔH_v^o = 10.69 kcal. mole⁻¹, is based on the vapor pressure data of Scott et al., loc. cit., series III. Vapor pressure measurements of Hieber and Woerner, loc. cit., and E. T. Cheng and N. A. Okken, AD-458286, Defense Documentation Center, January, 1964, are in satisfactory agreement as shown below.

Source	Temp. Range °K.	ΔH _v ^o 298 (kcal. mole ⁻¹) 2nd Law	3rd Law e.u.	3rd Law Drift
Scott, et al. (1949)	273-343	10.683 ± 0.003	10.696	0.05 ± 0.01
Cheng, Gocken (1964)	276-325	10.40 ± 0.03	10.68	0.91 ± 0.09
Hieber, Woerner (1934)	293-387	10.82 ± 0.03	10.71	-0.33 ± 0.07

The second law-third law consistency of Scott et al. reflects the use of these data in selection of the gas phase functions (see H₂N₂ gas).

Dec. 31, 1965

Bond Distances: N-H = 1.022 Å N-N = 1.449 Å

Bond Angle: H-N-H = 109.4° H-N-N = 112.0°

Torsional angle between two NH₂ groups ≥ 90° from eclipsed position.Product of the Moments of Inertia: I_AI_BI_C = 7.307 X 10⁻¹¹⁷ g.³ cm.⁶

Heat of Formation.

This was obtained from the heat of formation of the liquid and the selected heat of vaporization, ΔH_v^o = 10.69 kcal. mole⁻¹, derived from the vapor pressure data (Series III) of D. W. Scott, G. D. Oliver, M. E. Gross, W. N. Hubbard and H. M. Huffman, J. Am. Chem. Soc. **71**, 2293 (1949). Other vapor pressure data from W. Hieber and A. Noerner, Z. Elektrochem. **40**, 252 (1934) and E. T. Chang and N. A. Gokcen, AD-458288, Defense Documentation Center, January, 1964, are in satisfactory agreement (see N₂H₄ liquid table).

Heat Capacity and Entropy.

Functions were calculated from the constants given above using the rigid rotor harmonic oscillator method. The entropy was increased by R ln 2 because two rotameric forms are implied by use of the torsional frequency. Small but arbitrary adjustments were made in the assignment of the bending mode frequencies in order to reproduce the vapor pressure data of Scott et al., loc. cit., as closely as possible. Calculated values of S₂₉₈ = 57.03 and S₃₄₀ = 59.70 cal. deg.⁻¹ mole⁻¹ may be compared with 56.89 and 59.69, respectively, derived from the data of Scott et al.. Internal rotation calculations would require a complex potential function in order to fit the data. The barrier to inversion (990 cm.⁻¹ ~ 2.8 kcal.) is slightly less than the barrier to internal rotation at the trans position (1110 cm.⁻¹ ~ 3.2 kcal.) according to analyses of the microwave data by T. Keesee, Sci. Papers, Inst. Phys. Chem. Res. (Tokyo) **55**, No. 1, 1-39 (1962) and T. Keesee and T. Kojima, J. Phys. Soc. Japan **18**, 364-8 (1963).

From matrix isolation and gas phase infrared studies, E. Catalano, R. H. Sanborn and J. W. Frezer, J. Chem. Phys. **39**, 2265 (1963), have suggested possible uncertainties in the assignment of the bending mode frequencies in the region from 1630 to 740 cm.⁻¹. The question hinges on the uncertain existence of a gas phase fundamental at about 1600 cm.⁻¹ as observed by P. A. Diguere and I. D. Liu, J. Chem. Phys. **20**, 136 (1952). No corresponding matrix band was found and the gas phase band appeared to be due to absorption on the cell windows. A vapor phase Raman frequency at 1564 cm.⁻¹ was observed, however, by Yu. I. Kotov and V. M. Tatevskii, Opt. i Spektroskopiya **15**, 65 (1963). Catalano et al. suggest one assignment based on the uncertain fundamental and a tentative alternative assignment excluding it. The two assignments give entropies that are 0.26 cal. deg.⁻¹ mole⁻¹ lower and 0.12 higher than the third law value. The lower calculated entropy is probably more reasonable, but the higher value could be more easily modified to agree with the third law value. Thus the alternative assignment was adopted with ν_{11} arbitrarily increased from ~810 to 935 cm.⁻¹.

The structural constants are based primarily on the electron diffraction study of Y. Morino, T. Iijima and Y. Murata, Bull. Chem. Soc. Japan **33**, 46 (1960). Related analyses of the infrared fine structure of the torsional frequency (377 cm.⁻¹), A. Yamasaki, I. Ichihama, T. Shimomouchi and S. Mizushima, Spectrochim. Acta **16**, 1471 (1960), and of the microwave spectra, Keesee and Kojima, loc. cit., are in close agreement. The microwave data give an H-N-H angle of 106° and a torsional angle of 90°. Principal moments of inertia of the adopted structure are I_A = 0.574 X 10⁻³⁹, I_B = 3.573 X 10⁻³⁹ and I_C = 3.563 X 10⁻³⁹ g. cm.²

MERCURY (Hg)

(REFERENCE STATE)

MOL. WT. = 200.61

The reference state is chosen as follows:

O° to 234.29°K Crystal

234.29° to 629.73°K Liquid

629.73° to 800°K Ideal Gas

$$S^{\circ}_{298.15} = 18.171 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H^{\circ}_{298.15} = 14.652 \pm 0.015 \text{ kcal. mole}^{-1}$$

$$\Delta H^{\circ}_m = 0.5486 \pm 0.0001 \text{ kcal. mole}^{-1}$$

$$\Delta H^{\circ}_v = 629.73 \pm 0.020 \text{ kcal. mole}^{-1}$$

$$T_m = 234.29^{\circ}\text{K}$$

$$T_b = 629.73^{\circ}\text{K}$$

Heat Capacity.

The heat capacities of P. L. Smith and N. M. Wolcott, Phil. Mag. **1** (8), 854 (1956), 1.2°-20.2°K, R. H. Busey and W. P. Olsauque, J. Am. Chem. Soc. **75**, 806 (1953), 15°-350°K, and N. B. Douglas, A. P. Ball, and D. C. Oirmings, J. Research Natl. Bur. Standards, **46**, 334 (1951), 300°-770°K, have been smoothly joined. There is fair agreement between the selected values and those of O. L. Pickard and P. E. Simon, Proc. Phys. Soc. A**61**, 1 (1948), L. G. Carpenter and P. H. Oakley, Phil. Mag. **12**, 511 (1931), L. O. Carpenter and L. G. Stoodley, Phil. Mag. **10**, 249 (1930), E. Cohen, O. I. Krutshauer, and A. L. Moenvald, Z. phys. Chem. **A95**, 437 (1920), A. L. Dixon and W. H. Rodenbush, J. Am. Chem. Soc. **49**, 1182 (1927), P. Simon, Z. phys. Chem. **107**, 282 (1923), Ann. Physik **58**, 241 (1922), J. N. Brünsted, Z. Elektrochem. **18**, 714 (1912), and P. Pollitzer, Z. Elektrochem. **17**, 5 (1911).

Melting Data.

From Busey and Olsauque, loc. cit.

Boiling Point and Heat of Vaporization.

Calculated from the vapor pressures determined by K. D. Carlson, R. J. Thorn, and P. W. Gilles, private communication, October 1961, P. M. Ernberger and H. W. Pitman, Rev. Sci. Instrum. **26**, 584 (1955), P. H. Spedding and J. L. Dye, J. Phys. Chem. **59**, 561 (1955), and J. A. Beattie, B. E. Blaisdell, and J. Kaminsky, Proc. Am. Acad. Arts Sciences **71**, 375 (1937). Earlier measurements are less accurate and have not been used. Gas imperfection has been allowed for by the method of Busey and Olsauque, loc. cit.

MERCURY MONIODIDE (HgI)

(IDEAL GAS)

Ground State Configuration 2_2 $\Delta H_f^\circ 298.15 = 31.9 \pm 1.1$ kcal mole⁻¹ $S_{298.15}^\circ = 67.068$ cal deg⁻¹ mole⁻¹

Electronic Level and Multiplicity

 $\frac{E, \text{cm}^{-1}}{0}$ $\frac{g_i}{2}$ $\omega_e = 125.0$ cm⁻¹ $\omega_e x_e = 1.00$ cm⁻¹ $\sigma = 1$ $B_e = [0.0351]$ cm⁻¹ $\alpha_e = [0.0003]$ cm⁻¹ $r_e = [2.49]$ Å

Heat of Formation

K. Wieland and A. Herzog, Helv. Chim. Acta, **32**, 869 (1949) gave 8.3 ± 1.1 kcal for the heat of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants were taken from K. Wieland, Zeits. f. Elektrochemie **54**, 761 (1960). Rotational constants were estimated using equation III 123, p. 108, G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York 1950. The bond length was estimated to be 0.965 of the mercuric bond length by analogy with the mercury chlorides.

MERCURY DIIODIDE (HgI₂)

(Crystal)

Mol. Wt. = 454.43

ΔH_f⁰ 298.15 = -25.2 ± 0.4 kcal. mole⁻¹

S_{298.15}⁰ = [43.338] ± 1.5 cal. deg.⁻¹ mole⁻¹

T_c = 402°K

ΔH_t⁰ = 0.601 ± 0.04 kcal. mole⁻¹

T_m = 530°K

ΔH_m⁰ = 4.533 ± 0.05 kcal. mole⁻¹

Heat of Formation. Taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties", (1952).

Heat Capacity and Entropy. The heat capacity was calculated from the heat content data of M. Guinchant, Comp. Rend. 89, 145 (1907) and R. Ewald, Ann. d. Physik (4) 44, 1213 (1914). The entropy was estimated by adjusting its value to provide the best fit of the melting, sublimation and vaporization phenomena.

Transition. The heat and temperature of transition were taken from National Bureau of Standards Circular 500 (loc. cit.).

Melting. The heat of melting was taken from M. Guinchant (loc. cit.), the temperature of melting from National Bureau of Standards Circular 500 (loc. cit.).

MERCURY DIIODIDE (HgI₂) (Liquid)

Mol. Wt. = 454.43
 ΔH_f^0 298.15 = [-20.862] ± 0.45 kcal. mole⁻¹
 ΔF_f^0 298.15 = [51.544] ± 1.5 cal. deg.⁻¹ mole⁻¹
 T_m = 530°K
 ΔH_m = 4.533 ± 0.05 kcal. mole⁻¹
 T_b = 627°K
 ΔH_v = 14.141 ± 0.25 kcal. mole⁻¹

Heat of Formation. Calculated from ΔH_f^0 298(c).

Heat Capacity and Entropy. Heat capacity measurements were obtained from the data of M. Guinchant, Comp. Rend. 68, 145 (1907) in the range 540-600°K and were assumed constant above and below this range. A glass type transition was assumed at 353°K below which the heat capacity was that of HgI₂(c). The entropy was calculated from the entropy of the crystal and the measured entropy of fusion.

Fusion and Vaporization. T_m and T_b are taken from National Bur. of Standards (U.S.) Circular 500 (1952). ΔH_m is from the data of M. Guinchant (loc. cit.) and ΔH_v was obtained from the data of E. B. R. Pridoux, J. Chem. Soc. (London) 97, 2032 (1910) and F. M. G. Johnson, J. Amer. Chem. Soc. 53, 777 (1931).

Mercury Diiodide (HgI₂) (Ideal Gas) Mol. Wt. = 454.43

 $\left\{ \begin{matrix} 1 \\ 233 \end{matrix} \right\}$

Hg-I distance = 2.58 Å
 Moment of Inertia = 280.5 X 10⁻³⁹ g. cm.² $\sigma = 2$

Heat of Formation. The heat of formation of the crystal as given in National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties", 1952 was combined with the 3rd law heat of sublimation at 298°K derived from the data of K. Niwa and Z. Shibata, J. Pac. Sci. Hokkaido Imp. Univ. Ser. III 2, 183 (1938); D. W. Magee, Univ. Microfilms No. 14474 Ann Arbor, Mich., and P. M. G. Johnson, J. Amer. Chem. Soc. 52, 777 (1911).

Heat Capacity and Entropy. The vibrational constants were given by W. Klemperer and L. Lindeman, J. Chem. Phys. 25, 397 (1956). The anti-symmetric stretching frequency was estimated by analogy with the bromide and chloride. The bond length was an average of the values given by H. Braune and S. Kroke, Naturwiss. 21, 349 (1933); A. H. Gregg, O. C. Hampson, G. I. Jenkins, P. L. P. Jones and L. E. Sutton, Trans. Farad. Soc. 33, 852 (1937) and P. A. Akshin, V. P. Spiridonov and A. N. Khodachenkov, Zhur. Fiz. Khim. 33, 20 (1959).

MERCURY MONOXIDE (HgO)

(CRYSTAL)

MOL. WT. = 216.61

$$\Delta H_f^o 298.15 = -21.699 \pm 0.024 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^o = 16.795 \pm 0.03 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_{\text{decomp}} = 749^\circ\text{K.}$$

Heat of Formation.

Obtained from the entropy obtained by T. W. Bauer and H. L. Johnston, J. Am. Chem. Soc. 75, 2217 (1953) and the free energy of formation as determined from the numerous cell measurements described by Bauer and Johnston. The value adopted for $\Delta F_f^o 298.15$ was $-42,707 \pm 14 \text{ cal. mole}^{-1}$.

Heat Capacity and Entropy.

The heat capacity has been measured from 15° to 298°K. by Bauer and Johnston loc. cit. The extrapolation below 15°K was done assuming a T^3 law and gave $S_{15}^o = 0.264 \text{ e.u.}$ Above 298° the data was extrapolated smoothly and adjusted to give the observed decomposition vapor pressures of G. B. Taylor and G. A. Hulett, J. Phys. Chem. 17, 565 (1913).

Decomposition.

According to Taylor and Hulett, loc. cit., the vapor pressure reaches 1.89 atmospheres at 749°K. This corresponds to the decomposition to 2 Hg(g) + O₂(g), the equilibrium constant being unity at 1.89 atm.

Electronic Levels and Quantum Weights

ϵ_i° , cm $^{-1}$	g_i
0	1
$\omega_e X_e = [4.7]$ cm $^{-1}$	$\sigma = 1$
$\omega_e = [680]$ cm $^{-1}$	
$B_e = [0.336]$ cm $^{-1}$	$r_e = [1.84]$ Å
$\alpha_e = [0.00277]$ cm $^{-1}$	

Heat of Formation

The heat of formation (ΔH_f°) of HgO(g) is estimated to be 10 ± 15 kcal/mol. This value is obtained from the heat of formation of PbO(g) and comparison of the heats of formation of analogous lead and mercury compounds using the method of Karapet'yants (1). The corresponding dissociation energy (D_0°) of HgO(g) is 64 ± 15 kcal/mol.

Heat Capacity and Entropy

The equilibrium internuclear separation (r_e) of HgO(g) is estimated from the corresponding quantity for PbO(g) and comparison of Hg-X and Pb-X bond distances for cases in which values of both distances are known. The rotational constant B_e is calculated from r_e . The fundamental vibrational frequency ω_e is estimated from Guggenheimer's relation for multiple bonded molecules (2). The anharmonic vibrational term $\omega_e X_e$ is calculated from $\omega_e X_e = \omega_e^2/(4D_0 + 2\omega_e)$. The value of α_e is calculated from the Morse potential function. The ground state configuration is estimated from the building-up principle (3), the united atom theory (3), and from analogy with BeO.

MERCURY MONOIODIDE, DIMERIC (Hg₂I₂) (Crystal)

Mol. Wt. = 655.04

ΔH_f 298.15 = -28.462 ± 0.5 kcal. mole⁻¹

S° 298.15 = 57.670 ± 2.0 cal. deg.⁻¹ mole⁻¹

T_m = 563°K

ΔH_m = [6.5] ± 2.0 kcal. mole⁻¹

Heat of Formation. The average value of the cell measurements of W. C. Vosburgh, J. Amer. Chem. Soc. 50, 2386 (1928); E. Cohen Zeits. f. physik. Chemie 94, 210 (1920); T. Yoshida, J. Chem. Soc. Japan 48, 435 (1927); L. W. Øholm, Acta. Soc. Scientiarum Fennicae 41, 1 (1913) and the calorimetric values of R. Varot, Ann. Chim. Phys. (7) 9, 91 (1896) and W. Nernst, Zeits. f. physik. Chemie 2, 23 (1888) was adopted.

Heat Capacity and Entropy. The heat capacity at 298.15° was taken from National Bureau of Standards (U.S.) Circular 500 (1952) and was estimated above this by analogy with mercurous chloride. The entropy was obtained from the heat and free energy of formation obtained from the cell measurements listed under heat of formation.

Melting. P. Yvon, Comp. Rend. 76, 1607 (1973) gives 563°K for the melting point. The heat of melting was estimated by assuming the entropy of melting per atom to be the same as that for mercuric iodide.

MERCURY MONIODIDE, DIMERIC (Hg₂I₂)

(Liquid)

Mol. Wt. = 655.04

ΔH_f^o 298.15 = [-23.021 ± 2.5] kcal. mole⁻¹

S_{298.15}^o = [66.868 ± 5.0] cal. deg. ⁻¹ mole⁻¹

T_m = 563°K

ΔH_m = [6.5 ± 2.0] kcal. mole⁻¹

T_b = [530]°K (decomp.)

Heat of Formation. Calculated from ΔH_f^o (crystal) and the estimated heat of melting and heat capacity.

Heat Capacity and Entropy. C_p was estimated as 1.33 times the heat capacity of mercuric iodide. The entropy was calculated from S^o crystal, the estimated ΔH_m and the heat capacities of solid and liquid.

Melting and Vaporization. The melting point was given by P. Yvon, Comp. Rend. 76, 1607 (1873); the heat of melting was estimated from that of mercuric iodide, by assuming the entropies of melting per atom to be equal. Mercurous iodide decomposes to Hg(s) and HgI₂(s) at the boiling point which was estimated from the free energy change of the reaction.

Thermodynamic Functions.

Atomic constants were taken from G. E. Moore [U. S. Natl. Bur. Standards Circ. 467, Vol. III (1958)]. The higher levels were averaged. Calculated thermodynamic functions are in good agreement with those of W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards, 55, 147 (1955)].

Heat of Formation.

The dissociation energy of diatomic iodine is given as D₀^o = 12452.5 ± 1.5 cm.⁻¹ by R. D. Verma [J. Chem. Phys. 32, 758 (1960)]. Converting to calories and combining with the heat of sublimation of iodine yields the heat of formation of the ideal monatomic gas. Evans, Munson, and Wagman [loc. cit.] list several investigations of the dissociation energy from equilibrium data. These are all less precise than the spectroscopic value and are not given any weight. The "best" average of the thermal data yields D₀^o = 35.588 kcal. mole⁻¹ (spectroscopic = 35.608 kcal. mole⁻¹).

Dec. 31, 1961; June 30, 1967

$\Delta H^{\circ}_0 = -78.14 \pm 0.1 \text{ kcal/mol}$
 $\Delta H^{\circ}_{298.15} = -78.37 \pm 0.1 \text{ kcal/mol}$
 $\Delta H^{\circ} = 5.74 \text{ kcal/mol}$
 $\Delta H^{\circ}_{298.15}(\text{to monomer}) = 48.37 \text{ kcal/mol}$
 $\Delta H^{\circ}_{298.15}(\text{to dimer}) = 55.84 \text{ kcal/mol}$

Heat of Formation

The heats of solution of KI(c) have been critically reviewed by V. B. Perker, U. S. Natl. Bur. Std. NBS-2, 1965. Six pertinent results are quoted in the table below. Adopting the best value, $\Delta H^{\circ}_{298} = 4.86 \pm 0.03 \text{ kcal/mol}$, reported by Parker, and $\Delta H^{\circ}_{298} = -60.32$ and -13.19 kcal/mol for $K^+(\text{H}_2\text{O})$ and $I^-(\text{H}_2\text{O})$, respectively, obtained from U.S. Natl. Bur. Std. Tech. Note 270-1, 1965, we obtain $\Delta H^{\circ}_{298}(\text{KI, c}) = -78.37 \pm 0.1 \text{ kcal/mol}$, which is adopted.

*Values are adjusted to 298.15°K and to infinite dilution.

**n is the number of moles of H_2O per mole of KI(c) in solution.

Heat Capacity and Entropy

The low temperature heat capacities are based on those measured by W. T. Berg and J. A. Morrison, *Proc. Roy. Soc. (London)* **A242**, 467 (1957), 2.86 - 268.0°K. The adopted values are in good agreement with the Cp values reported by W. W. Seales, *Phys. Rev.* **112**, 49 (1958), 2 - 7°K. The data of K. Clusius, J. Goldmann, and A. Perlick, *Z. Naturforsch.* **4A**, 424 (1949), 10.27 - 269.9°K, appear to be too low in the temperature range 70 - 270°K and are not used. Low temperature enthalpies, 83 - 273°K, have been measured by F. Koref, *Ann. Physik* **5**, 49 (1911). The value of S°_{298} is derived based on the adopted low temperature heat capacities, using $S^{\circ}_{298} = 0.0033 \text{ eu}$.

The high temperature enthalpies were determined by S. M. Skuratov and S. A. Lapushkin, *Russ. J. Gen. Chem. (English Transl.)* **21**, 2485 (1951), 623 - 923°K; A. S. Dworin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tenn., Dec. 1, 1964, 854 - 954°K; and C. B. Cooper, *J. Chem. Phys.* **21**, 777 (1953), 297 - 973°K. Heat Capacities are derived from the enthalpies by a curve fitting method which requires a smooth joint with the low temperature Cp. Enthalpy values used in the curve fit include smooth values calculated from the equation of Skuratov and the value $H^{\circ}_{934} - H^{\circ}_{298} = 9.2 \text{ kcal/mol}$ from Dworin. Deviation of the input values from the selected enthalpies are all less than 0.3 percent, while the deviations of the data of Cooper range from ± 1.0 percent at 570°K to -1.6 percent at 974°K. Since the latter point is 20° above the melting point, there appears to be an error in Cooper's measurement of temperature. Cp above the melting point is obtained by graphical extrapolation.

Melting Data

Tm has been reported to be 953, 952 and 954°K by R. C. Ray and V. Daval, *Trans. Faraday Soc.* **32**, 741 (1936); T. E. Phipps and E. G. Partridge, *J. Am. Chem. Soc.* **51**, 1331 (1929); and J. W. Johnson and M. A. Bredig, *J. Phys. Chem.* **52**, 604 (1958), respectively. The last value is adopted. The heat of melting was determined by A. S. Dworin and M. A. Bredig, *J. Phys. Chem.* **54**, 269 (1960), using drop calorimetry.

Heat of Sublimation

The difference between ΔH°_{298} for KI(g) and KI(c) is $\Delta H^{\circ}_{298}(\text{to monomer})$. The $\Delta H^{\circ}_{298}(\text{to dimer})$ is calculated as the enthalpy change for the following reaction: $2\text{KI(c)} = \text{K}_2\text{(g)}$.

POTASSIUM IODIDE (KI)

(LIQUID)

GFW = 166.0064

$$\Delta H_f^{\circ} = -74.771 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 5.74 \text{ kcal/mol}$$

$$\Delta H_v^{\circ} = 45.62 \text{ kcal/mol}$$

$$S_{298.15}^{\circ} = 27.273 \text{ gibbs/mol}$$

$$T_m = 954^{\circ}\text{K}$$

$$T_b = 1618^{\circ}\text{K}$$

Heat of Formation

The heat of formation, ΔH_f° , is obtained from ΔH_f° (KI, c) by adding ΔH_m° and the difference between $H_{954}^{\circ} - H_{298}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is derived as 17.3 gibbs/mol from the enthalpy measurements, 954 - 1014°K, by A. S. Dworin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tenn., Dec. 1, 1964. This Cp value is adopted in the temperature range 298 - 2500°K. S_{298}° is obtained in a manner analogous to that of the heat of formation.

Melting Data

See KI(c) table for details.

Vaporization Data

The boiling point, $T_b = 1618^{\circ}\text{K}$, is calculated as the temperature at which the sum of the partial pressures of KI(g) and $K_2I_2(g)$ over KI(l) equals one atmosphere. The value of ΔH_v° is calculated as the heat required to produce one mole of vapor mixture, which contains 78 percent monomer (KI) and 22 percent dimer (K_2I_2) at T_b .

T_b was reported as 1603 and 1590°K by H. von Wartenberg and P. Albrecht, Z. Elektrochem. **21**, 162 (1921), and O. Ruff and S. Mugdan, Z. Anorg. Chem. **117**, 147 (1921), respectively.

Heat of Formation

The heat of formation is derived from the sublimation and vaporization data analyzed below. Many investigators have determined the total pressures of KI(g) and KI₂(g) over KI(l) by static methods or "apparent" pressures by Knudsen effusion or transpiration. These pressures are converted to monomer pressures by use of functions [see K₂I₂(g) table] which are consistent with the dimer-monomer equilibrium data of Batz (9). Second and third law analyses of the monomer pressures show reasonable agreement. The selected value of ΔH_{f,298}° = -30.0 ± 0.5 kcal/mol is also in good agreement with -30.23 ± 1.15 and -30.46 kcal/mol derived from D₀° = 3.32 ± 0.05 and 3.33 eV reported by Gaydon (10) and Herzberg (11), respectively.

Heat Capacity and Entropy

The ground state configuration is obtained from Herzberg (11). The adopted values of ω_e , $\omega_e x_e$, B_e , α_e , and r_e were determined using millimeter wave molecular beam spectroscopy by Rusk and Gordy (12), and corrected to the average isotopic species. Similar values were reported by Honig et al. (13) from microwave spectra, except ω_e which was given as 169.74 cm⁻¹. The value of ω_e was derived to be 200 and 173 cm⁻¹ by Barrow and Caunt (14) and Rice and Klemperer (15). The moment of inertia is 4.5979 × 10⁻³⁸ g cm².

LITHIUM IODIDE (LiI)

(CRYSTAL)

OPW = 133.8434

ILI

 $\Delta H^\circ_f = \text{Unknown}$ $\Delta H^\circ_{298.15} = -64.55 \pm 0.1 \text{ kcal/mol}$ $\Delta H^\circ_m = 3.50 \text{ kcal/mol}$ $S^\circ_{298.15} = [20.5] \text{ gibbs/mol}$ $T_m = 742^\circ\text{K}$

Heat of Formation.

The heat of formation, $\Delta H^\circ_{298}(\text{LiI}, c) = -64.55 \text{ kcal/mol}$, was calculated from the heat of solution of lithium iodide (c) at infinite dilution and the ionic heats of formation of $\text{Li}^+(\text{aq})$ and $\text{I}^-(\text{aq})$.

V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NBS-RS-NBS 2, Apr. 1, 1965, reviewed the literature heat of solution data and gave the "best" value, $\Delta H^\circ_{298}(\text{LiI}, c) = -15.130 \pm 75 \text{ cal/mol}$ for $\text{LiI}(c) \rightarrow \text{Li}^+(\text{aq}) + \text{I}^-(\text{aq})$ at 298.15°K . The ionic heat of formation, $\Delta H^\circ_{298}(\text{Li}^+, \text{aq}) = -66.49 \text{ kcal/mol}$ was calculated from $\Delta H^\circ_{298}(\text{LiOH} \cdot \text{aq}) = -121.46 \text{ kcal/mol}$ (see JANAF LiOH(c) Table, Mar. 31, 1966) with $\Delta H^\circ_{298}(\text{OH}^-, \text{aq}) = -54.97 \text{ kcal/mol}$ from NBS Technical Note 270-1, "Selected Values of Chemical Thermodynamic Properties," Oct. 1, 1965. The value $\Delta H^\circ_{298}(\text{I}^-, \text{aq}) = -13.19 \text{ kcal/mol}$ was also obtained from NBS Technical Note 270-1. Combination of the ionic heats of formation of $\text{Li}^+(\text{aq})$ and $\text{I}^-(\text{aq})$ gives the heat of formation of $\text{LiI}(\text{aq})$, $\Delta H^\circ_{298} = -79.68 \text{ kcal/mol}$.

Heat Capacity and Entropy.

A. S. Dworin, private communication, Oak Ridge National Laboratory, Dec. 1964, has measured the enthalpy changes by the drop method ($642\text{-}802^\circ\text{K}$), yielding $(H^\circ_{742} - H^\circ_{298}) = 6.0 \text{ kcal/mol}$ for the crystal at the melting point. Heat capacities derived from his data were $C_p 692^\circ = 14.8$ and $C_p 772^\circ = 15.1 \text{ cal/deg-mol}$ for the crystal and liquid, respectively. The tabulated heat capacities were estimated based on these values and on the heat capacities of $\text{LiCl}(c)$, $\text{NaCl}(c)$ and $\text{NaI}(c)$.

The entropy, $S^\circ_{298.15} = 20.5 \text{ eu}$, was estimated by adding the entropy difference between $\text{NaI}(c)$ and $\text{NaCl}(c)$ to the entropy of lithium chloride (c) at 298.15°K . Comparisons with other alkali halides give results within $\pm 0.5 \text{ eu}$ of this value.

K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960), 592 (1961), has estimated the heat capacities ($C_p = 12.30 + 2.44 \times 10^{-3} T$ gibbs/mol) and the entropy ($S^\circ_{298} = 17.50 \text{ eu}$).

Melting Data.

The selected heat of fusion ($\Delta H^\circ_{298} = 3.50 \text{ kcal/mol}$) was obtained from enthalpy measurements in a drop calorimeter by A. S. Dworin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960).

LITHIUM IODIDE (LiI)

(LIQUID)

GFW = 133.8434

 $\Delta H^\circ_{298.15} = [23.568] \text{ gkcal/mol}$ $\Delta H^\circ_{298.15} = -61.749 \text{ kcal/mol}$ $\Delta H^\circ_{298.15} = 3.50 \text{ kcal/mol}$ $\Delta H^\circ_{298.15} = 23.3 \text{ kcal/mol}$ $\Delta H^\circ_{298.15} = [32.6] \text{ kcal/mol}$ $T_m = 742^\circ\text{K}$ $T_b(\text{to equilibrium mixture}) = 1449^\circ\text{K}$ $T_b(\text{to monomer only}) = [1497]^\circ\text{K}$

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding the heat of fusion and the difference between $H^\circ_{742} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

A. S. Dworin, private communication, Oak Ridge National Laboratory, Dec. 1964, has derived the heat capacity, $C_p = 15.1 \text{ gkcal/mol}$, from enthalpy measurements, $742 - 802^\circ\text{K}$, by the drop method. The liquid heat capacity was assumed to be a constant, 15.1 gkcal/mol . The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See LiI(c) table for detail.

Vaporization Data.

T_b (to monomer only) is determined as the temperature at which the Gibbs energy change (ΔG°) for the reaction $\text{LiI(l)} = \text{LiI(g)}$ approaches zero. The corresponding enthalpy change (ΔH°) at boiling point is the heat of vaporization ΔH°_{298} (to monomer only).

T_b (to equilibrium mixture) is the temperature at which the sum of the calculated partial vapor pressures of LiI(g) and $\text{Li}_2\text{I}_2(\text{g})$ reaches one atmosphere (trimer and higher polymer have been neglected in calculation). This value is in good agreement with the boiling point of 1444°K from the least squares fit of the total vapor pressure data measured by O. Ruff and S. Mugdan, Z. anorg. Chem. **117**, 147 (1921). ΔH°_{298} (to equilibrium mixture) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 30.44 mole percent of dimer. For detailed information see LiI(g) and $\text{Li}_2\text{I}_2(\text{g})$ tables.

Heat of Formation.

The heat of formation (ΔH_f° , LiI, g) = $-21.75 \pm 2 \text{ kcal/mol}$ was calculated from the selected heat of sublimation and the heat of formation for lithium iodide (c). The heat of sublimation has been determined spectroscopically from the ion intensity measurement (2nd law method) by L. N. Gorokhov, Dokl. Akad. Nauk SSSR 142, 113 (1962), as $\Delta H_{sub}^\circ(\text{to monomer}) = 42.9 \pm 0.6$ and $\Delta H_{sub}^\circ(\text{to dimer}) = 43.2 \pm 0.4 \text{ kcal/mol}$ in the temperature range from 626-722°K. Gorokhov also reported the partial vapor pressure of monomeric lithium iodide ($P_{\text{monomer}} = 3 \times 10^{-3} \text{ mm Hg}$) and the ratio of dimer to monomer ($P_{\text{dimer}}/P_{\text{monomer}} = 6$) which have been used for third law calculation. Using the same technique, L. Friedman, J. Chem. Phys. 23, 477 (1955), reported the heats of sublimation as $\Delta H_{sub}^\circ(\text{to monomer}) = 41.9 \pm 0.5$ and $\Delta H_{sub}^\circ(\text{to dimer}) = 40.8 \pm 0.5 \text{ kcal/mol}$ in the temperature range from 630° to 730°K. J. Berkowitz, H. A. Tassman and W. A. Chupka, J. Chem. Phys. 36, 2170 (1962) have also studied the lithium iodide vapor in the mass spectrometer and reported the second law and third law values of the heat of dimerization at 800°K as 37.9 and 40.4 kcal/mol, respectively. Using the JANAF thermodynamic functions, all the heats of sublimation and dimerization at different temperatures have been reduced to 298°K and summarized in the following table. The total vapor pressure over the liquid has been measured by a boiling point method in the temperature range 1223° to 1413°K by O. Ruff and S. Muggen, Z. anorg. Chem. 117, 147 (1921). (Their data have been quoted by H. von Wartenberg and H. Schulz, Z. Elektrochem. 27, 568 (1921).) In order to have good agreement between the calculated vapor pressure and the observed total vapor pressure, the heats of sublimation have been so chosen as $\Delta H_{sub}^\circ(\text{to monomer}) = 42.8 \text{ kcal/mol}$ and $\Delta H_{sub}^\circ(\text{to dimer}) = 42.6 \text{ kcal/mol}$ and the heat of dissociation of dimer, $\Delta H_{298}^\circ = 43.0 \text{ kcal/mol}$. The calculated boiling point (to equilibrium mixture) is 1449°K which agrees with 1443°K reported by Wartenberg and Schulz, and also 1462°K by Ruff and Muggen.

Heat Capacity and Entropy.

The bond distance and the rotational constants (B_e and α_e), corrected to the isotopic abundance of 7.4% Li^6 and 92.6% Li^7 , were obtained from the microwave studies by A. Honig, M. Mendel, M. L. Stich and C. H. Townes, Phys. Rev. 96, 629 (1954). The vibrational constants (ω_e and $\omega_e x_e$) were determined from the infrared spectrum by W. Klemperer, W. O. Norris, A. Buehler and A. O. Enslie, J. Chem. Phys. 33, 1534 (1960).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by R. L. Wilkins, J. Chem. Eng. Data 5, 337 (1960), who used slightly different molecular constants.

Heat of Formation

The heat of formation ($\Delta H_{298.15}^{\circ}$) for NOI (g) is estimated by comparison with those for FNO(g), ClNO(g), BrNO(g), and the related cyanogen halides.

Heat Capacity and Entropy

The molecular structure and bond angle are estimated by comparison with those for ClNO(g) and BrNO(g). The N-O bond distance is assumed to be the same as that in NO(g). The N-I bond distance (r_{N-I}) is calculated based on an assumption that $r_{ON-Cl} - r_{ON-I} = r_{Cl-I} - r_{I-I}$. The vibrational frequencies are estimated by comparison with those for FNO(g), ClNO(g) and BrNO(g). The three principal moments of inertia are: $I_A = 8.834 \times 10^{-40}$, $I_B = 2.916 \times 10^{-38}$ and $I_C = 3.005 \times 10^{-38} \text{ g cm}^2$.

J. Wast, E. Lange, Z. physik. Chem. **116**, 161 (1925).
+1.75 ± 0.06
E. Lange, A. L. Robinson, Chem. Revs. **9**, 89 (1931).
Askew, Bullock, Smith, Tinkler, Gatty, Wolfenden, J. Chem. Soc., **1934**, 1368.

Heat Capacity and Entropy.

Smoothed heat capacities between 3° and 270°K. have been presented by W. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) **242A**, 467 (1957). Above 270°K. the heat capacity was obtained by comparing with KI(c) on a reduced temperature plot of C_p/T versus T . The values so obtained were increased by 1.4% to bring them into line with the low temperature data.

Melting Data.

A. Dworkin and M. Bredig, J. Phys. Chem. **64**, 269 (1960) have measured both T_m and ΔH_m .

Sept. 30, 1963

$$S_{298.15}^{\circ} = 28.862 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_f^{\circ} 298.15 = -63.695 \text{ kcal. mole}^{-1}$$

$$\Delta H_m = 5.64 \text{ kcal. mole}^{-1}$$

$$T_m = 933^{\circ}\text{K.}$$

$$T_b = 1577^{\circ}\text{K. (equilibrium mixture)}$$

Heat of Formation.

$\Delta H_f^{\circ} 298.15$ was calculated from the heat of formation of the crystal plus the heat of melting and the difference between $H_{933}^{\circ}H_{293}$ for crystal and liquid.

Heat Capacity and Entropy.

C_p was estimated assuming each atom contributed $7/5 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$. $S_{298.15}^{\circ}$ was calculated in a manner similar to $\Delta H_f^{\circ} 298.15$.

Melting Data.

See table for crystal.

Vaporization Data.

The boiling point is that given by K. K. Kelley, U. S. Bureau of Mines Bulletin 363, 1955 from examination of the high temperature vapor pressure.

June 30, 1952

Lead Moniodide (PbI) (Ideal Gas)

Mol. Wt. = 334.12

ΔH_f⁰ 298.15 = 25.7 ± 9.2 kcal. mole⁻¹

S_{298.15} = 66.855 cal. deg.⁻¹ mole⁻¹

Ground State Configuration ²Π_{1/2}

Electronic Levels and Multiplicities

ε, cm. ⁻¹	ε ₁
0	2
[8000]	2

ω_e = 160.5 cm.⁻¹ ω_ex_e = 0.25 cm.⁻¹

B_e = [0.02940] cm.⁻¹ α_e = [0.00000] cm.⁻¹

σ = 1

Heat of Formation. ΔH_f⁰ 298.15 was calculated from the dissociation energy of PbI(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ω_e and ω_ex_e were obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York, 1950. B_e and α_e were estimated by comparison with the corresponding values for the other diatomic halide molecules. Electronic levels and multiplicities were estimated from those for Pb(g).

Heat of Formation

The heat of formation, ΔH_{f298}° of TiI (g) is calculated from the dissociation energy, D_0° , which is estimated as 73 kcal/mol. This estimate is obtained from the relation $D(TiI_2) < D(TiI) < D(TiI_3)$, where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of TiF₂(g) by Zmbov and Margrave (1).

Heat Capacity and Entropy

The vibrational frequency, ω_e , and the anharmonic vibrational term, $\omega_e x_e$, are estimated from those of TiCl(g) and comparisons of the mercury and alkali monohalides. The interatomic distance is estimated from Guggenheimer's relation (2). B_e is calculated from r_e . The ground state term and electronic levels are estimated from the ground state multiplet of Ti⁺ (1). σ_e is estimated from the Morse potential function.

$$B_e = [0.03789] \text{ cm.}^{-1}$$

Heat of Formation

The dissociation energy was estimated from a correlation of the JANAP values for TiCl(g), TiI(g), and ZrCl(g). The resulting value, 29.7 kcal. mole⁻¹, was employed with auxiliary JANAP heats of formation for Zr(g) and I(g) in calculating ΔH_f^{298.15}.

Heat Capacity and Entropy

The vibrational frequency was estimated from those of TiI(g), TiCl(g), and the alkali halides. The ground state configuration was assumed to be analogous to the ground term of TiCl(g) as given by E. A. Shenoyakaya, et al., Optics and Spectroscopy, 12, 359 (1962). The internuclear distance was estimated from those of TiBr(g), TiI(g) and ZrI(g).

T, °K.	C _p	$\frac{\text{cal. mole}^{-1}\text{deg.}^{-1}}{S^\circ - (F^\circ - H_{298}^\circ)/T}$	$\frac{\text{kcal. mole}^{-1}}{H^\circ - H_{298}^\circ}$	ΔF°	Log K _P
