The replication files consist of two syntax files and a large collection of data files that are combined together for the analysis. There are two syntax files because the turnout and presidential vote analyses sometimes rely on different data sources and analytic decisions so it was more straightforward to separate them into separate files. **pandemic_election_turnout.R** contains the syntax necessary to replicate all the analysis where total turnout is the outcome variable. **pandemic_election_pvote.R** contains the syntax necessary to replicate all analysis where the presidential vote is the outcome variable. For the syntax to work properly, the working directory needs to be set to local values in the places indicated in the code.
