FOREWORD

The Pond Dynamics/Aquaculture Collaborative Research Support Program (PD/A CRSP) represents an international community of researchers and institutions dedicated to strengthening health and nutrition in developing countries by improving the efficiency of pond aquaculture systems. It is one of several agricultural CRSPs supported by the U.S. Agency for International Development under the authority of Title XII of the International Development and Food Assistance Act of 1975.

The "global experiment" in Pond Dynamics/Aquaculture is the major CRSP research activity, covering the period from 1982 to 1987. The global experiment was designed to quantitatively describe the physical, chemical and biological principles of pond culture systems. The information gained from the global experiment will be used to improve production technologies and develop quantitative production functions to facilitate rigorous economic analyses of aquaculture systems.

Standardization is a key element of the global experiment. Standardization permits the comparison of data from diverse geographic locations. The experimental design involves monitoring specified environmental and fish production variables in accordance with standardized work plans in twelve or more ponds at each of seven geographical locations. The variables observed, frequency of observation, and materials and methods are uniform for all locations. The field data are filed in a centralized data base, called the CRSP Data Base. Statistical methods will be used to test hypotheses about correlations between variables and to evaluate the sources of variance within ponds, between ponds within locations, and between locations.

The CRSP Data Base will be used to develop predictive models of the processes occurring in pond culture systems. The models will be used to: provide guidance for ongoing and future research; predict the performance of existing and proposed pond systems subject to specific inputs and constraints; and improve the operation and efficiency of pond culture systems.

The global experiment includes three cycles of experiments. Each cycle consists of two series of observations, one during the dry season and one during the wet season. The objective of the first cycle is to create a detailed baseline of chemical, physical, and biological data on all ponds treated with a standard level of inorganic fertilizer. In the second experimental cycle, ponds treated with inorganic fertilizer are compared to ponds treated with organic fertilizer. In the third cycle, the responses of ponds to different levels of organic fertilizer are compared.

The goal of the Pond Dynamics/Aquaculture Collaborative Research Data Reports (referred to as Data Reports) is to record the PD/A CRSP Data Base and to present interpretations of site specific results. The PD/A CRSP has conducted the global experiment at seven project sites in six developing countries: Thailand, Indonesia, the Philippines, Panama, Honduras, and Rwanda. The first volume of these reports provides descriptive information for each of the PD/A CRSP sites. It presents the physical characteristics of each site, including a geographical sketch, climatology, and water and soil analyses. Experimental cycles are described in PD/A CRSP Work Plans 1 to 3, which are summarized in the first volume.

Volume One will serve as the reference volume for the entire report series. Subsequent volumes will focus on each site separately. Each volume will include one cycle (wet and dry seasons) of the PD/A CRSP global experiment. Therefore, with few exceptions, each project site will have three volumes devoted to it, representing the results of the three cycles of the global experiment. Cycle I of the Global Experiment in Thailand is presented in this second volume.

INTRODUCTION

The Pond Dynamics/Aquaculture CRSP conducted a series of experiments on pond culture systems around the world. The first set of experiments was designed to evaluate pond dynamics under low nutrient input rates during wet and dry seasons. This report covers the first cycle for experiments conducted in Thailand. First cycle, dry season experiments were conducted from 5 January to 4 June 1984, in ten ponds at the Nong Sua Fish Hatchery, located 100 km northeast of Bangkok. First cycle, wet season experiments were conducted from 1 August to 31 December 1984, in 12 ponds at Ayutthaya Fishery Station, 60 km northwest of Bangkok.

The purpose of the first cycle experiments was to evaluate physical, chemical, and biological changes in aquaculture ponds treated with low nutrient input, and to determine the statistical variation between ponds.

MATERIALS AND METHODS

Ponds were monitored regularly for the physical, chemical and biological processes listed below. Frequency of the measurements varied from daily to monthly with each parameter. The specific variables measured and the frequency of measurement are described in Volume I of the Data Reports. Variables monitored included rainfall, air temperature, pond depth, ammonia, orthophosphate, dissolved oxygen, pH, mean fish weight, and total fish yield. Measurements at Ayutthaya also included alkalinity, hardness, nitrate-nitrite, total phosphorus, secchi disk depth, chlorophyll *a* concentration, primary productivity, solar radiation, and wind velocity.

Ponds were treated with P_2O_5 at 8 kg/ha/mo. They were stocked with Oreochromis niloticus at one fish per m^2. The experiment lasted 150 days. In addition to water and weather sampling, soil chemistry was analyzed for each site.

RESULTS

Pond soil characteristics at Nong Sua (Table 1a) and Ayutthaya (Table 1b) differ primarily with respect to pH. Nong Sua is characterized by acid-sulfate soil (pH 4.1) and Ayutthaya by slightly alkaline soil (pH 7.4). Pond soil analyses also showed differences in aluminum (40 ppm at Ayutthaya vs. 1131 ppm at Nong Sua), and to a smaller degree calcium, magnesium, and iron.

The meteorological data at Ayutthaya indicate that the wet season of 1984 was drier than the dry season, and had one-fifth or less of the level of precipitation in 1983 (Figure 1). Due partly to the lack of rain, air temperature was very warm during both seasons, with extremes of 17 and 42°C, and an average minimum of 26°C and maximum of 37°C. Most other weather parameters were similar with little variation for both seasons.

Physical characteristics of the ponds also showed the results of low rainfall in both seasons. Pond depth (Figure 2) was often less than 1 m, and fell to 0.6 m in spite of pumping to maintain water levels. Pond water temperatures were very warm with an average daily minimum of 27°C and maximum of 33°C. There was a large diel cycle of temperature, with daily fluctuations of 7 to 10°C.

The water chemistry at Nong Sua and Ayutthaya was similar. Ponds at both sites showed some

seasonal trends. Phosphate (Figure 3) and ammonia (Figure 4) were very low except immediately after fertilization. Phosphate and Ammonia showed variability between ponds, although this was more pronounced for ammonia. The low trophic state of the ponds is indicated by dissolved oxygen levels, which were generally high. Dissolved oxygen levels showed a very small diel excursion (Figure 5), and had little, if any, seasonal trends (Figure 6).

The biological data generated in this cycle were difficult to evaluate. Chlorophyll *a* levels in the pond were relatively consistent at Ayutthaya, but not at Nong Sua (Figure 7). However, at Ayutthaya, there was no correlation between chlorophyll *a* levels and primary productivity, which increased throughout the cycle (Figure 8). Also, primary productivity was not correlated with fish growth, which was consistent over time (Figure 9). Physical and biological data were often variable between ponds; however, there were no significant differences between ponds (Anova, $P>0.05$). Therefore, although pond trends were transient in time, they followed consistent overall averages.

Fish growth and yield were very similar in both seasons (Table 2). This occurred in spite of our poor record of sorting sexes during the dry season; the wet season yielded a more acceptable sex ratio. Mean survival of fish was very good (95%), while mean yield was low (376 kg/ha). This was due to very slow mean growth, only 0.28 g/day. (Normal growth is about 1 g/day.)

DISCUSSION

The pond dynamics of Cycle 1 were dominated by low nutrient input and low yield. The nutrient limitations appeared in both nitrogen and phosphorus. This should be taken into account in future experimental designs.

Due to weather, few differences were noted in production for wet and dry season data. Whether this is typical of all locations or due to our circumstances remains to be seen.

The changing of sites also had little or no effect on our data. The only clear difference between Ayutthaya and Nong Sua is that variances between ponds in chemical parameters, especially chlorophyll *a*, was very high at Nong Sua. Apparently, liming corrected most low pH effects at Nong Sua, at least over our experimental period.

Finally, the low correlation between primary productivity and fish yield indicates some basic problems in design. Either our methods are inadequate to determine this correlation, or else Tilapia primarily utilize other energy pathways. Utilization or detritus for food by Tilapia is not being evaluated in our experiment.
