— Replication package —

† Corresponding author. If you have any questions, please get in touch with Gábor Scheiring at gs1098@georgetown.edu.

The replication material contains the following files:

/code_hlthmigr
- dataset_hlthmigr.do — code for creating and cleaning the datasets used in the analyses
- descriptives_hlthmigr.do — code for creating the descriptive statistics
- analyses_hlthmigr.do — code for the main results
- robustness.do — code for the robustness tests

/data_ess
- place the ESS master files here, see instructions in dataset_hlthmigr.do

/data_hlthmigr
- folder for the analysis dataset

/output_hlthmigr
- folder for the outputs

Before running the replication code, please make sure that you have these folders created in your working directory and modify the .do files to change the working directory.

When you start the analysis, the code should be in the code_hlthmigr folder and the ESS master data files should be in the /data_ess folder (master datasets were pulled from the ESS Data Portal on July 25, 2024 https://ess.sikt.no/en/?tab=overview). The /data_hlthmigr and /output_hlthmigr folders are empty before running the code. After you download the ESS master data files, you need to run dataset_hlthmigr.do before you can run the other do files.

The code was tested before uploading and should run without error. However, note that the large number of fixed effects can cause convergence issues in structural equation models depending on the version of Stata and the version of the ESS master files. Managing this might require some experimentation with the right set of dummies.
