December 2015

The 2014 Kenya Demographic and Health Survey (2014 KDHS) was implemented by the Kenya National Bureau of Statistics from May 2014 to October 2014 in partnership with the Ministry of Health, the National AIDS Control Council (NACC), the National Council for Population and Development (NCPD), and the Kenya Medical Research Institute (KEMRI). Funding for the KDHS was provided by the Government of Kenya with support from the United States Agency for International Development (USAID), the United Nations Population Fund (UNFPA), the United Kingdom Department for International Development (DfID), the World Bank, the Danish International Development Agency (DANIDA), the United Nations Children's Fund (UNICEF), the German Development Bank (KfW), the Clinton Health Access Initiative (CHAI), the World Food Programme (WFP), and the Micronutrient Initiative (MI). ICF International provided technical assistance for the survey through The DHS Program, a USAID-funded project that helps implement population and health surveys in countries worldwide.

Additional information about the 2014 KDHS may be obtained from the Kenya National Bureau of Statistics (KNBS), P.O. Box 30266-00100 GPO Nairobi, Kenya; telephone (Nairobi): 3317586/8, 3317612/22, 3317623, 3317651; fax: 3315977; e-mail: directorgeneral@knbs.or.ke, info@knbs.or.ke; website: www.knbs.or.ke.

Information on The DHS Program may be obtained from ICF International, 530 Gaither Road, Suite 500, Rockville MD, 20850, USA; telephone: 301-407-6500; fax: 301-407-6501; e-mail: info@DHSprogram.com; website: www.DHSprogram.com.

CONTENTS

TABLES AND FIGURES ..... **ix**
FOREWORD ..... **xvii**
MILLENNIUM DEVELOPMENT GOAL INDICATORS ..... **xix**
SUMMARY OF FINDINGS ..... **xxi**
MAP OF KENYA ..... **xxvi**

1 INTRODUCTION **1**
1.1 History, Geography, and Economy 1
1.1.1 History 1
1.1.2 Geography 1
1.1.3 Economy 1
1.2 Population 1
1.3 Population and Health Policy Frameworks 2
1.3.1 Population Policy Framework 2
1.3.2 Health Priorities and Programmes 3
1.4 Objectives of the Survey 3
1.5 Survey Organisation 4
1.6 Sample Design 5
1.7 Questionnaires 5
1.8 Training 7
1.8.1 Training of Trainers 7
1.8.2 Pretest Activities 7
1.8.3 Main Training of Field Staff 7
1.9 Fieldwork 8
1.10 Data Processing 8
1.11 Response Rates 9

2 HOUSING CHARACTERISTICS AND HOUSEHOLD POPULATION **11**
2.1 Household Characteristics 11
2.1.1 Water and Sanitation 12
2.1.2 Housing Characteristics 14
2.1.3 Household Possessions 16
2.2 Household Wealth 17
2.3 Food Security 18
2.4 Hand Washing 19
2.5 Household Population by Age and Sex 20
2.6 Household Composition 21
2.7 Birth Registration 22
2.8 Children's Living Arrangements, Orphanhood, and School Attendance 23
2.9 Education of the Household Population 25
2.9.1 Educational Attainment 25
2.9.2 School Attendance Ratios 27

3 CHARACTERISTICS OF RESPONDENTS **31**
3.1 Characteristics of Survey Respondents 31
3.2 Educational Attainment by Background Characteristics 34
3.3 Literacy 39

3.4 Access to Mass Media 44
3.5 Employment 49
3.5.1 Employment Status 49
3.5.2 Occupation 51
3.5.3 Earnings, Employers, and Continuity of Employment 53

4 MARRIAGE AND SEXUAL ACTIVITY 55
4.1 Current Marital Status 55
4.2 Polygyny 56
4.3 Age at First Marriage 58
4.4 Age at First Sexual Intercourse 60
4.5 Recent Sexual Activity 62

5 FERTILITY 65
5.1 Current Fertility 65
5.2 Fertility Differentials 66
5.3 Fertility Trends 69
5.4 Children Ever Born and Living 70
5.5 Birth Intervals 71
5.6 Postpartum Amenorrhoea, Abstinence, and Insusceptibility 74
5.7 Menopause 75
5.8 Age at First Birth 75
5.9 Teenage Pregnancy and Motherhood 78

6 FERTILITY PREFERENCES 81
6.1 Desire for More Children 81
6.2 Desire to Limit Childbearing by Background Characteristics 82
6.3 Ideal Family Size 84
6.4 Fertility Planning 86
6.5 Wanted Fertility Rates 87

7 FAMILY PLANNING 89
7.1 Introduction 89
7.2 Knowledge of Contraceptive Methods 89
7.3 Current Use of Contraception 93
7.4 Current Use of Contraception by Background Characteristics 94
7.5 Trends in Current Use of Contraception 95
7.6 Timing of Sterilisation 97
7.7 Source of Contraception 97
7.8 Informed Choice 98
7.9 Contraceptive Discontinuation Rates 99
7.10 Reasons for Discontinuation of Contraceptive Use 100
7.11 Knowledge of Fertile Period 101
7.12 Need and Demand for Family Planning Services 101
7.13 Future Use of Contraception 104
7.14 Exposure to Family Planning Messages 105
7.15 Contact of Nonusers with Family Planning Providers 106
7.16 Men's Knowledge of and Attitudes towards Contraceptive Use 107

8 INFANT AND CHILD MORTALITY 111
8.1 Data Quality 112
8.2 Levels and Trends in Infant and Child Mortality 113
8.3 Socioeconomic Differentials in Infant and Child Mortality 115

8.4 Demographic Differentials in Infant and Child Mortality 116
8.5 Perinatal Mortality 117
8.6 High-Risk Fertility Behaviour 118

9 MATERNAL HEALTH 121
9.1 Antenatal Care 121
9.1.1 Number and Timing of Antenatal Visits 123
9.1.2 Components of Antenatal Care 124
9.2 Tetanus Toxoid Vaccination 126
9.3 Place of Delivery 127
9.4 Assistance during Delivery 129
9.5 Postnatal Care 132
9.5.1 Timing of First Postnatal Checkup for the Mother 132
9.5.2 Provider of First Postnatal Checkup for the Mother 133
9.5.3 Timing of First Postnatal Checkup for the Newborn 134
9.5.4 Provider of First Postnatal Checkup for the Newborn 135
9.6 Problems in Accessing Health Care 136
9.7 Fistula 137

10 CHILD HEALTH 139
10.1 Child's Weight and Size at Birth 140
10.2 Vaccination Coverage 141
10.3 Acute Respiratory Infection 145
10.4 Fever 147
10.5 Diarrhoeal Disease 150
10.6 Knowledge of ORS Packets and Zinc Tablets 154
10.7 Disposal of Children's Stools 155

11 NUTRITION OF CHILDREN AND WOMEN 157
11.1 Nutritional Status of Children 158
11.1.1 Measurement of Nutritional Status among Young Children 158
11.1.2 Data Collection 158
11.1.3 Measures of Child Nutritional Status 159
11.1.4 Trends in Children's Nutritional Status 163
11.2 Breastfeeding and Complementary Feeding 163
11.2.1 Initiation of Breastfeeding 163
11.2.2 Breastfeeding Status by Age 165
11.2.3 Duration of Breastfeeding 167
11.2.4 Types of Complementary Foods 168
11.2.5 Infant and Young Child Feeding (IYCF) Practices 169
11.3 Micronutrient Intake among Children 172
11.4 Iodisation of Household Salt 176
11.5 Nutritional Status of Women 177
11.6 Micronutrient Intake among Mothers 180

12 MALARIA 183
12.1 Introduction 183
12.2 Ownership of Mosquito Nets 185
12.3 Access to Insecticide-Treated Nets 188
12.4 Use of Mosquito Nets 189
12.4.1 Overall Use of Mosquito Nets 189
12.4.2 Use of Mosquito Nets by Children Under Age 5 194
12.4.3 Use of Mosquito Nets by Pregnant Women 197

12.5 Preventive Malaria Treatment During Pregnancy 198
12.6 Fever among Children Under Age 5 201
12.6.1 Prevalence and Treatment of Fever among Children 201
12.6.2 Type and Timing of Antimalarial drugs 204

13 HIV/AIDS-RELATED KNOWLEDGE, ATTITUDES, AND BEHAVIOUR 207
13.1 Introduction 207
13.2 HIV and AIDS Knowledge, Transmission and Prevention Methods 208
13.2.1 Awareness of HIV and AIDS 208
13.2.2 Knowledge of HIV Prevention Methods 210
13.2.3 Rejection of Misconceptions about HIV/AIDS 213
13.2.4 Knowledge of Mother-to-Child Transmission of HIV 218
13.3 Attitudes towards People Living with HIV and AIDS 221
13.4 Attitudes towards Negotiating Safer Sexual Relationships 224
13.5 Attitude towards Condom Education for Youth 225
13.6 High-Risk Sex 227
13.6.1 Multiple Partners and Condom Use 227
13.6.2 Point Prevalence and Cumulative Prevalence of Concurrent Sexual Partners 229
13.6.3 Transactional Sex 231
13.7 Coverage of HIV Counselling and Testing 234
13.7.1 General HIV Testing 234
13.7.2 HIV Counselling and Testing During Pregnancy 239
13.8 Male Circumcision 241
13.9 Self-Reporting of Sexually Transmitted Infections 242
13.10 Prevalence of Medical Injections 244
13.11 HIV/AIDS Knowledge and Sexual Behaviour among Youth 245
13.11.1 HIV/AIDS-Related Knowledge among Youth 246
13.11.2 Trends in Age at First Sex 247
13.11.3 Abstinence and Premarital Sex 249
13.11.4 Multiple Sexual Partners among Youth 250
13.11.5 Cross-generational Sexual Partners 251
13.11.6 Voluntary HIV Counselling and Testing among Youth 252

14 NONCOMMUNICABLE DISEASES AND OTHER HEALTH ISSUES 255
14.1 Introduction 255
14.2 Knowledge of and Screening for Cancer 255
14.2.1 Breast Cancer 255
14.2.2 Cervical Cancer 256
14.2.3 Prostate Cancer 257
14.3 Screening for Hypertension and Diabetes 258
14.4 Knowledge and Attitudes Concerning Tuberculosis 259
14.5 Use of Tobacco 261
14.6 Alcohol Consumption 263
14.7 Physical Activity 265
14.8 Unintentional Injury 267
14.9 Health Insurance Coverage 269

15 WOMEN'S EMPOWERMENT AND DEMOGRAPHIC AND HEALTH OUTCOMES 273
15.1 Employment and Form of Earnings 273
15.2 Control over and Relative Magnitude of Women's and Husbands' Earnings 274
15.2.1 Control over Wife's Earnings 275
15.2.2 Control over Husbands' Earnings 276

15.3 Control over Women's Earnings and Relative Size of Husband's and Wife's Earnings 277
15.4 Ownership of Assets 277
15.5 Women's Participation in Decision Making 279
15.6 Attitudes towards Wife Beating 283
15.7 Women's Empowerment Indices 286
15.8 Current Use of Contraception by Women's Status 286
15.9 Ideal Family Size and Unmet Need by Women's Status 287
15.10 Reproductive Health Care and Women's Empowerment 288
15.11 Differentials in Infant and Child Mortality by Women's Status 289

16 DOMESTIC VIOLENCE 291
16.1 Measurement of Violence 291
16.1.1 Use of Valid Measures of Violence 291
16.1.2 Ethical Considerations in the 2014 KDHS 293
16.1.3 Subsample for the Violence Module 293
16.2 Experience of Physical Violence 293
16.3 Perpetrators of Physical Violence 296
16.4 Experience of Sexual Violence 297
16.5 Perpetrators of Sexual Violence 300
16.6 Age at First Experience of Sexual Violence 301
16.7 Experience of Different Forms of Violence 302
16.8 Violence during Pregnancy 303
16.9 Marital Control by Spouse 303
16.10 Forms of Spousal Violence 306
16.11 Spousal Violence by Background Characteristics 309
16.12 Violence by Spousal Characteristics and Women's Empowerment Indicators 311
16.13 Recent Spousal Violence 314
16.14 Onset of Spousal Violence 315
16.15 Physical Consequences of Spousal Violence 316
16.16 Violence by Women and Men against Their Spouse 317
16.17 Violence against Spouses by Spousal Characteristics and Women's Empowerment Indicators 320
16.18 Help-seeking Behaviour by Women and Men Who Experience Violence 322

17 ADULT AND MATERNAL MORTALITY 327
17.1 Data and Assessment of Quality 327
17.2 Estimates of Adult Mortality 328
17.3 Estimates of Maternal Mortality 329

18 FEMALE GENITAL CUTTING 331
18.1 Knowledge of Female Circumcision 331
18.2 Prevalence of and Age at Circumcision 333
18.3 Aspects of Circumcision among Circumcised Girls and Women 337
18.4 Religious and Community Attitudes towards FGC 339
18.5 Support for the Continuation of FGC 342

FOREWORD

The 2014 Kenya Demographic and Health Survey (KDHS) provides information to help monitor and evaluate population and health status in Kenya. The survey, which follows up KDHS surveys conducted in 1989, 1993, 1998, 2003, and 2008-09, is of special importance for several reasons. New indicators not collected in previous KDHS surveys, such as noncommunicable diseases, fistula, and men's experience of domestic violence, are included. Also, it is the first national survey to provide estimates for demographic and health indicators at the county level. Following adoption of a constitution in Kenya in 2010 and devolution of administrative powers to the counties, the new 2014 KDHS data should be valuable to managers and planners.

The 2014 KDHS has specifically collected data to estimate fertility, to assess childhood, maternal, and adult mortality, to measure changes in fertility and contraceptive prevalence, to examine basic indicators of maternal and child health, to estimate nutritional status of women and children, to describe patterns of knowledge and behaviour related to the transmission of HIV and other sexually transmitted infections, and to ascertain the extent and pattern of domestic violence and female genital cutting. Unlike the 2003 and 2008-09 KDHS surveys, this survey did not include HIV and AIDS testing. HIV prevalence estimates are available from the 2012 Kenya AIDS Indicator Survey (KAIS), completed prior to the 2014 KDHS.

Results from the 2014 KDHS show a continued decline in the total fertility rate (TFR). Fertility decreased from 4.9 births per woman in 2003 to 4.6 in 2008-09 and further to 3.9 in 2014, a one-child decline over the past 10 years and the lowest TFR ever recorded in Kenya. This is corroborated by the marked increase in the contraceptive prevalence rate (CPR) from 46 percent in 2008-09 to 58 percent in the current survey. The decline in fertility accompanies a marked decline in infant and child mortality. All early childhood mortality rates have declined between the 2003 and 2014 KDHS surveys. Total under-5 mortality declined from 115 deaths per 1,000 live births in the 2003 KDHS to 52 deaths per 1,000 live births in the 2014 KDHS. The maternal mortality ratio is 362 maternal deaths per 100,000 live births for the seven-year period preceding the survey; however, this is not statistically different from the ratios reported in the 2003 and 2008-09 KDHS surveys and does not indicate any decline over time.

The proportion of mothers who reported receiving antenatal care from a skilled health provider increased from 88 percent to 96 percent between 2003 and 2014. The percentage of births attended by a skilled provider and the percentage of births occurring in health facilities each increased by about 20 percentage points between 2003 and 2014. The percentage of children age 12-23 months who have received all basic vaccines increased slightly from the 77 percent observed in the 2008-09 KDHS to 79 percent in 2014. Six in ten households (59 percent) own at least one insecticide-treated net, and 48 percent of Kenyans have access to one. In malaria endemic areas, 39 percent of women received the recommended dosage of intermittent preventive treatment for malaria during pregnancy. Awareness of AIDS is universal in Kenya; however, only 56 percent of women and 66 percent of men have comprehensive knowledge about HIV and AIDS prevention and transmission.

The 2014 KDHS was conducted as a joint effort by many organisations. The Kenya National Bureau of Statistics (KNBS) served as the implementing agency by providing guidance in the overall survey planning, development of survey tools, training of personnel, data collection, processing, analysis, and dissemination of the results. The Bureau would like to acknowledge and appreciate the institutions and agencies for roles they played that resulted in the success of this exercise: Ministry of Health (MOH), National AIDS Control Council (NACC), National Council for Population and Development (NCPD), Kenya Medical Research Institute (KEMRI), Ministry of Labour, Social Security and Services, United States Agency for International Development (USAID/Kenya), ICF International, United Nations Fund for

Population Activities (UNFPA), the United Kingdom Department for International Development (DfID), World Bank, Danish International Development Agency (DANIDA), United Nations Children's Fund (UNICEF), German Development Bank (KfW), World Food Programme (WFP), Clinton Health Access Initiative (CHAI), Micronutrient Initiative (MI), US Centers for Disease Control and Prevention (CDC), Japan International Cooperation Agency (JICA), Joint United Nations Programme on HIV/AIDS (UNAIDS), and the World Health Organization (WHO). The management of such a huge undertaking was made possible through the help of a signed memorandum of understanding (MoU) by all the partners and the creation of active Steering and Technical Committees. The Bureau is grateful to all the staff from various institutions and agencies who worked tirelessly to ensure the success of this exercise.

Special thanks go to all the KNBS staff, survey personnel, and ICF International staff who worked long hours to collect data and most important, to the respondents who gave time to provide the information from which this report is developed.

Zachary Mwangi
Director General
Kenya National Bureau of Statistics

MILLENNIUM DEVELOPMENT GOAL INDICATORS

Kenya 2014

Indicator	Sex		
	Male	Female	Total
1. Eradicate extreme poverty and hunger			
1.8 Prevalence of underweight children under 5 years of age	12.1	9.8	11.0
2. Achieve universal primary education			
2.1 Net attendance ratio in primary education[1]	85.5	87.6	86.6
2.3 Literacy rate of 15-24 year-olds[2]	94.6[a]	92.8	93.7[b]
3. Promote gender equality and empower women			
3.1 Ratio of girls to boys in primary, secondary and tertiary education			
3.1a Ratio of girls to boys in primary education[3]	na	na	1.0
3.1b Ratio of girls to boys in secondary education[3]	na	na	1.1
3.1c Ratio of girls to boys in tertiary education[3]	na	na	0.9
4. Reduce child mortality			
4.1 Under five mortality rate[4]	60	52	52
4.2 Infant mortality rate[4]	44	37	39
4.3 Percentage of 1 year old children immunised against measles	87.9	86.2	87.1
5. Improve maternal health			
5.1 Maternal mortality ratio[5]	na	na	362 *(CI: 254,471)*
5.2 Percentage of births attended by skilled health personnel[6]	na	na	61.8
5.3 Contraceptive prevalence rate[7]	na	58.0	na
5.4 Adolescent birth rate[8]	na	96.3	na
5.5 Antenatal care coverage			
5.5a At least one visit[9]	na	95.5	na
5.5b Four or more visits[10]	na	57.6	na
5.6 Unmet need for family planning	na	17.5	na
6. Combat HIV/AIDS, malaria and other diseases			
6.2 Condom use at last higher-risk sex[11]	75.0[a]	58.7	66.8
6.3 Percentage of the population age 15-24 years with comprehensive correct knowledge of HIV/AIDS[12]	63.7	54.2	59.0
6.4 Ratio of school attendance of orphans to school attendance of non-orphans age 10-14 years	0.98	1.01	0.99
6.7 Percentage of children under 5 sleeping under insecticide-treated bednets[13]	55.0	53.5	54.3
6.8 Percentage of children under 5 with fever who are treated with appropriate antimalarial drugs[14]	27.0	27.0	27.0
	Urban	Rural	Total
7. Ensure environmental sustainability			
7.8 Percentage of population using an improved water source[15]	85.7	57.0	66.9
7.9 Percentage of population using an improved sanitation facility[16]	30.5	21.6	24.7

na = Not applicable

[1] The ratio is based on reported attendance, not enrolment, in primary education among primary school age children (6-13 year-olds). The rate also includes children of primary school age enrolled in secondary education. This is a proxy for MDG indicator 2.1, Net enrolment ratio.

[2] Refers to respondents who attended secondary school or higher or who could read a whole sentence or part of a sentence

[3] Based on reported net attendance, not gross enrolment, among 6-13 year-olds for primary, 14-17 year-olds for secondary and 18-22 year-olds for tertiary education

[4] Expressed in terms of deaths per 1,000 live births. Mortality by sex refers to a 10-year reference period preceding the survey. Mortality rates for males and females combined refer to the 5-year period preceding the survey.

[5] Expressed in terms of maternal deaths per 100,000 live births in the 7-year period preceding the survey

[6] Among births in the five years preceding the survey

[7] Percentage of currently married women age 15-49 using any method of contraception

[8] Equivalent to the age-specific fertility rate for women age 15-19 for the 3-year period preceding the survey, expressed in terms of births per 1,000 women age 15-19

[9] With a skilled provider

[10] With any healthcare provider

[11] Higher-risk sex refers to sexual intercourse with a non-marital, non-cohabiting partner. Expressed as a percentage of men and women age 15-24 who had higher-risk sex in the past 12 months.

[12] Comprehensive knowledge means knowing that consistent use of a condom during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting the AIDS virus, knowing that a healthy-looking person can have the AIDS virus, and rejecting the two most common local misconceptions about transmission or prevention of the AIDS virus

[13] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment, or (2) a net that has been soaked with insecticide within the past 12 months

[14] Measured as the percentage of children age 0-59 months who were ill with a fever in the two weeks preceding the interview and received any anti-malarial drug

[15] Percentage of de jure population whose main source of drinking water is a household connection (piped), public tap or standpipe, tubewell or borehole, protected dug well, protected spring, rainwater collection, or bottled water

[16] Percentage of de jure population whose household has a flush toilet, ventilated improved pit latrine, pit latrine with a slab, or composting toilet and does not share this facility with other households

[a] Restricted to men in sub-sample of households selected for the male interview

[b] The total is calculated as the simple arithmetic mean of the percentages in the columns for males and females

SUMMARY OF FINDINGS

HOUSEHOLD POPULATION AND CHARACTERISTICS

Housing

The majority (71 percent) of households in Kenya have access to an improved source of drinking water. Twenty-three percent of households have an improved toilet facility that is not shared with other households. The majority (64 percent) of households in Kenya do not have electricity. Almost half (46 percent) of households live in dwellings with cement floors. More than half (53 percent) of households use one room for sleeping. More than half (56 percent) of households use wood as their main source of cooking fuel.

Education, Media, and Mobile Phones

The percentage of women and men with no education has dropped by half over the last 10 years, from 13 percent and 6 percent in 2003 to 7 percent and 3 percent, respectively, in the 2014 KDHS. Over the same period, the percentage of women and men with at least some secondary education increased from 29 percent and 37 percent in 2003 to 43 percent and 49 percent, respectively, in 2014. Eighty-eight percent of women and 92 percent of men are literate. Twenty-three percent of women and 10 percent of men are not exposed to any source of mass media. Eighty-six percent of households own mobile phones.

Employment

Sixty-one percent of women and 80 percent of men are currently employed. Women are mostly employed in agricultural or domestic service positions, while men are mostly employed in agricultural, unskilled manual, or domestic service positions.

MARRIAGE AND SEXUAL ACTIVITY

The median age at first marriage among women age 25-49 is 20.2 years; the median age at first marriage among men age 30-49 is 25.3 years. Median age at marriage has remained stable in the past 10 years for both women and men. Six percent of currently married men are in a polygynous union; 11 percent of currently married women have co-wives. The percentage of women married by age 15 appears to be declining; 9 percent of women age 45-49 were married by age 15, as compared with 2 percent among those age 15-19. Fifteen percent of women age 20-49 had first sexual intercourse by age 15, 50 percent by age 18, and 71 percent by age 20. Twenty-two percent of men age 20-49 had first sexual intercourse by age 15, 56 percent by age 18, and 76 percent by age 20.

FERTILITY

Fertility Levels and Trends

The total fertility rate for the three years preceding the survey is 3.9 births per woman, with rural women having at least one child more than urban women. Fertility has decreased from 4.9 births per woman in 2003 to 3.9 births per woman in 2014, a one-child decline in the past 10 years. Half of births occur within three years of a previous birth, with 18 percent occurring within 24 months. Childbearing begins early in Kenya, with almost one-quarter of women giving birth by age 18 and nearly half by age 20. Eighteen percent of adolescent women age 15-19 are already mothers or pregnant with their first child. In the last five years, teenage pregnancy has remained unchanged.

Fertility Preferences

Half of currently married women age 15-49 and 42 percent of currently married men age 15-49 want no more children or are sterilised. The mean ideal number of children among all women age 15-49 is 3.6, while that of all men is 3.9. The mean ideal number of children among women has declined marginally in the last 10 years from 3.9 in the 2003 KDHS to 3.6 in 2014. The gap between actual fertility and ideal family size has narrowed in the last 10 years, from 1.3 children in 2003 to 1.0 in 2014.

Family Planning

More than half of currently married women (58 percent) use a contraceptive method. The most popular modern contraceptive methods used by married women are injectables (26 percent), implants (10 percent), and the pill (8 percent). Use of modern methods has increased over the last decade from 32 percent in the 2003 KDHS to 53 percent in 2014. The public sector remains the major provider of contraceptive methods; 60 percent of modern contraceptive users obtain their contraception from a government source. Thirty-one percent of family planning users discontinue use of a method within 12 months of starting its use. Side effects and health concerns (11 percent) are the main reason for discontinuation. Eighteen percent of currently married women have an unmet need for family planning services, with 9 percent in need of spacing and 8 percent in need of limiting.

MATERNAL HEALTH

Antenatal Care

Ninety-six percent of women with a live birth in the five years preceding the survey received antenatal care from a skilled provider, an improvement from 92 percent in the 2008-09 KDHS and 88 percent in the 2003 KDHS. Fifty-eight percent of women make the recommended four or more antenatal care visits during their pregnancy, an increase of 11 percentage points from the 2008-09 KDHS (47 percent).

Delivery, Postnatal, and Newborn Care

Sixty-one percent of live births in the five years preceding the survey were delivered in a health facility; 62 percent were assisted by a skilled provider. More than half (53 percent) of women who gave birth in the two years before the survey received a postnatal care checkup in the first two days after delivery. Thirty-six percent of infants born in the two years before the survey had their first postnatal checkup within the first two days after birth. One in three newborns received postnatal care from a doctor, a nurse, or a midwife.

Fistula

More than half (54 percent) of the women interviewed in the survey had heard of fistula. However, only 1 percent of these women reported having ever experienced fistula-like symptoms.

CHILD HEALTH

Childhood Mortality

The infant mortality rate is 39 deaths per 1,000 live births, and under-5 mortality is 52 deaths per 1,000 live births. At these levels, about one in every 26 Kenyan children dies before reaching age 1, and about one in every 19 does not survive to his or her fifth birthday. All early childhood mortality rates declined between the 2003 and 2014 KDHS surveys. Neonatal mortality has exhibited the slowest rate of decline (33 percent). A child born in the Nyanza region is almost twice as likely to die before age 5 as a child born in the Central region. Nairobi has the second highest under-5 mortality rate, following Nyanza (72 deaths per 1,000 live births). Male children are more likely than female children to die during their first year of life (44 deaths versus 37 deaths per 1,000 live births). Once past infancy, male and female children one to four years of age experience the same level of mortality (16 deaths per 1,000 live births). The neonatal mortality rate for the five years preceding the survey is 22 deaths per 1,000 live births, 1.4 times the postneonatal rate. The perinatal mortality rate for the same reference period is 29 deaths per 1,000 pregnancies.

Childhood Vaccination Coverage

Seventy-nine percent of children age 12-23 months have received all basic vaccines, slightly higher than the 77 percent observed in the 2008-09 KDHS.

Childhood Illness and Treatment

Nine percent of children under age 5 showed symptoms of acute respiratory infection in the two weeks before the survey; 66 percent of these children were taken to a health facility or provider for advice or treatment. Twenty-four percent of children under age 5 had a fever in the two weeks before the survey; 63 percent of these children were taken to a health facility or provider for advice or treatment. Fifteen percent of children under age 5 had diarrhoea in the two weeks before the survey. The proportion of children with diarrhoea taken to a health provider for advice or treatment

increased from 49 percent in the 2008-09 KDHS to 58 percent in the 2014 KDHS. The proportion of children with diarrhoea given fluid from ORS packets has increased over the past five years, from 39 percent in 2008-09 to 54 percent in 2014. The percentage of women who know that ORS can be used to treat diarrhoea in children has increased from 78 percent in 2008-09 to 93 percent in 2014. The percentage of children whose stools are disposed of safely has increased from 78 percent in 2008-09 to 83 percent in 2014.

NUTRITION

Nutritional Status of Children

Twenty-six percent of children under age 5 are stunted, 4 percent are wasted, and 11 percent are underweight.

Nutritional Status of Women

Nine percent of women age 15-49 are thin or undernourished (BMI <18.5 kg/m^2); 33 percent of women are either overweight or obese (BMI ≥25 kg/m^2), with 10 percent of them being obese (BMI ≥30 kg/m^2).

Breastfeeding Practices

Ninety-nine percent of children have ever been breastfed; however, only 61 percent of children less than age 6 months are exclusively breastfed. Complementary foods are generally introduced at the recommended age; 81 percent of breastfed children age 6-9 months received complementary foods in the 24 hours preceding the survey. Only 22 percent of children are fed in accordance with the three recommended infant and young child feeding practices.

Supplements and Deworming for Children and Women

Seventy-two percent of children age 6-59 months received vitamin A supplements in the past six months. Fifty-one percent of children age 12-59 months received deworming medication in the same time period. Among women, only 8 percent took iron tablets daily for 90 or more days during the pregnancy of their last birth. Thirty-one percent of women took deworming medication during their last pregnancy.

MALARIA

Net Ownership and Use

Six in 10 households (59 percent) own at least one insecticide-treated mosquito net (ITN), while 34 percent of households have at least one net for every two people. Forty-eight percent of Kenyans have access to an ITN. Two-fifths of the household population (42 percent) slept under an ITN the night prior to the survey, and two-thirds (67 percent) of members of households with at least one ITN slept under an ITN the night prior to the survey. Fifty-four percent of children under age 5 slept under an ITN the night before the survey, and, among those living in households with an ITN, 77 percent slept under an ITN the night before the survey. Fifty-one percent of pregnant women overall slept under an ITN the night before the survey, and, among those living in households with an ITN, 77 percent slept under an ITN the night before the survey.

Pregnant Women and Children

Seventeen percent of women received intermittent preventive treatment (IPTp) for malaria during pregnancy; that is, they received two or more doses of SP/Fansidar, at least one during an antenatal care visit. In malaria endemic areas, 39 percent of women received IPTp. Twenty-three percent of children under age 5 who had a fever took ACT, and 13 percent took ACT within 24 hours of fever onset.

HIV/AIDS

Awareness of and Knowledge about AIDS

Awareness of AIDS is universal in Kenya. However, only 56 percent of women and 66 percent of men have comprehensive knowledge about HIV and AIDS prevention and transmission; that is, they know that both condom use and limiting sexual intercourse to one uninfected partner can prevent HIV, they are aware that a healthy-looking person can have HIV, and they reject the two most common local misconceptions about HIV: that HIV can be transmitted by mosquitoes and by sharing food. Seventy-two percent of women and 62 percent of men know both that HIV can be transmitted through breastfeeding and that the risk

of mother-to-child transmission can be reduced by taking special drugs during pregnancy.

HIV-related Behavioural Indicators

Among respondents who had more than one sexual partner in the past 12 months, 40 percent of women and 44 percent of men reported using a condom during their last sexual intercourse.

HIV Testing

Since the 2008-09 KDHS, there has been an increase in the percentage of both women (from 29 percent to 53 percent) and men (from 23 percent to 46 percent) who were tested for HIV in the past 12 months and received their results. Sixty-eight percent of women who gave birth in the two years before the survey received HIV counselling during antenatal care. Almost 7 in 10 women (69 percent) were tested for HIV during antenatal care and received the test results and post-test counselling, while 23 percent received results but did not receive post-test counselling.

OTHER HEALTH ISSUES

Ten percent of women have had both a breast exam from a health provider and a breast self-exam. Three-quarters (76 percent) of women have heard of cervical cancer, and 14 percent have had a cervical cancer screening exam. Approximately two-thirds (65 percent) of men have heard of prostate cancer, and 3 percent have been examined by a doctor or health care provider for prostate cancer. Tobacco use is more common among Kenyan men than women (83 percent of men don't use tobacco compared with 99 percent of women). Sixteen percent of men smoke cigarettes. Among men who smoke cigarettes, 28 percent smoked more than 10 cigarettes in the past 24 hours. Most Kenyans do not have health insurance; 82 percent of women and 79 percent of men are not covered by any health insurance.

WOMEN'S EMPOWERMENT

Nearly half (49 percent) of currently married employed women who earn cash make independent decisions about how to spend their earnings, an increase from the figure of 42 percent reported in the 2008-09 KDHS. Fifty-four percent of currently married women participate in decisions pertaining to their own health care, major household purchases, visits to their family or relatives, and major household purchases. Thirty-nine percent of women have the main say in their own health care.

Contraceptive use increases with women's empowerment. In general, unmet need for family planning decreases with improvements in women's empowerment. Access to antenatal care, delivery assistance from a skilled provider, and postnatal care within the first two days of delivery increases with increasing women's empowerment.

GENDER-BASED VIOLENCE

Violence Since Age 15

Forty-five percent of women and 44 percent of men age 15-49 have experienced physical violence since age 15, and 20 percent and 12 percent, respectively, experienced physical violence within the 12 months prior to the survey. The main perpetrators of physical violence against women are husbands, whereas the main perpetrators against men are parents, teachers, and others.

Sexual and Partner Violence

Fourteen percent of women and 6 percent of men age 15-49 report having experienced sexual violence at least once in their lifetime. Overall, 39 percent of ever-married women and 9 percent of men age 15-49 report having experienced spousal physical or sexual violence. Among women and men who have ever experienced spousal violence (physical or sexual), 39 percent and 24 percent, respectively, reported experiencing physical injuries. Forty-four percent of women and 27 percent of men have sought assistance to stop the violence they have experienced.

Female Genital Cutting

Twenty-one percent of women age 15-49 have been circumcised. There is some evidence of a trend over time to circumcise girls at younger ages. Twenty-eight percent of circumcised women age 20-24 were circumcised at age 5-9, as compared with 17 percent of circumcised women age 45-49. With respect to type of circumcision, 2 percent of circumcised women age 15-49 had cutting with no flesh removed, 87 percent had cutting with flesh removed, and 9 percent had their genital area sewn

closed after cutting (a procedure known as infibulation). Girls age 0-14 are more likely to be circumcised if their mother is circumcised. Likewise, girls age 0-14 are more likely to be infibulated if their mother is also infibulated. Eight percent of girls age 0-14 have had their genital area sewn closed. Eleven percent or less of women and men believe that the practice of female genital cutting is required by their community or their religion or that the practice should continue.

ADULT AND MATERNAL MORTALITY

Fourteen percent of women and 18 percent of men are likely to die between exact ages 15 and 50. Maternal deaths account for 14 percent of all deaths to women age 15-49. The maternal mortality ratio was 362 maternal deaths per 100,000 live births for the seven-year period preceding the survey. When comparing the estimate of an MMR of 362 with the MMR estimated in the previous DHS (2008-09 KDHS estimate of 520 maternal deaths per 100,000 live births), the differential is not large enough to conclude whether or not there has been any change over time between the two surveys.

INTRODUCTION 1

Macdonald Obudho, James N. Munguti, John K. Bore, Mutua Kakinyi

1.1 HISTORY, GEOGRAPHY, AND ECONOMY

1.1.1 History

Kenya is a former British colony. The independence process was met with resistance and an armed struggle by Kenyans against the British colonial rulers. The Mau Mau rebellion in the 1950s paved the way for constitutional reform and political development in the following years. The country achieved self-rule in June 1963 and gained independence on December 12, 1963. The country was a multi-party state until 1981, when it was converted to a single-party state by amending the constitution. Kenya reverted to the multi-party state in 1992. The Kenya African National Union (KANU) ruled the country from independence to 2002, when the National Alliance of Rainbow Coalition (NARC) was elected to power. To date, the multi-party state remains, with the Jubilee Coalition currently in power.

1.1.2 Geography

Kenya is situated in the eastern part of the African continent. The country lies between 5 degrees north and 5 degrees south latitude and between 24 and 31 degrees east longitude. The equator passes at the middle, separating the upper and lower parts almost equally. Kenya borders Ethiopia (north), Somalia (northeast), Tanzania (south), Uganda (west), and South Sudan (northwest). The Indian Ocean is on the eastern side. The coastline houses the port of Mombasa, which enables Kenya and several other countries, including Uganda, Rwanda, and South Sudan, to engage in global trade.

The country is administratively divided into 47 counties. It has a total of 582,646 square kilometres, of which 571,466 square kilometres are the dry land area. Most of the land area (80 percent) is arid or semi-arid, and only 20 percent is arable. The country has diverse physical features: Mount Kenya, the second highest mountain in Africa; Lake Victoria, the largest freshwater lake on the continent; the Great Rift Valley, which runs from north to south; and Lake Nakuru, a major tourist attraction due to the presence of flamingos.

The country falls within two regions: lowlands, including the coastal and lake region lowlands, and highlands, which fall on both sides of the Great Rift Valley. Rainfall and temperatures are influenced by altitude and proximity to the Indian Ocean. The coastal region has a tropical climate, with both rainfall and temperatures higher than the rest of the country throughout the year.

1.1.3 Economy

The Kenyan economy is predominantly agricultural with a strong industrial base. The performance of the Kenyan economy since the country gained independence has been mixed. Recent years have seen an estimated 5-6 percent growth. From the demand side, growth has mainly been driven by an increase in private consumption and rapid growth in capital investment. From the supply side, the major drivers of the economy have been agriculture, forestry, and fishing; construction wholesale and retail trade; education; and finance and insurance.

1.2 POPULATION

Kenya's population was enumerated at 38.6 million in the 2009 census (Table 1.1). The trend data from population censuses indicate that the total population more than tripled between 1969 and 2009.

These data also suggest that the population increased by approximately one million people per year between 1999 (28.7 million) and 2009. The inter-censal growth rate, which was 3.3 percent per annum in 1969, increased to a peak of 3.8 percent per annum in 1979 before declining to 2.9 percent per annum in 1999. At a growth rate of 2.9 percent per annum, the population may increase to 77 million by 2030.

Table 1.1 Basic demographic indicators

Selected demographic indicators for Kenya, 1969, 1979, 1989, 1999, 2009, and 2014

Indicator	1969	1979	1989	1999	2009	2014
Population (millions)	10.9	16.2	23.2	28.7	38.6	43.0[a]
Density (pop/km^2)	19.0	27.0	37.0	49.0	66.4	73.9[a]
Percent urban	9.9	15.1	18.1	19.4	32.3	32.3[c]
Crude birth rate	50.0	54.0	48.0	41.3	34.8	30.5[c]
Crude death rate	17.0	14.0	11.0	11.7	10.4	10.4[b]
Inter-censal growth rate	3.3	3.8	3.4	2.9	2.9	2.9[b]
Total fertility rate	7.6	7.8	6.7	5.0	4.8	3.9[c]
Infant mortality rate (per 1,000 births)	119	88	66	77.3	54.0	39.0[c]
Life expectancy at birth	50	54	60	56.6	58.0	58.0[b]

1.3 POPULATION AND HEALTH POLICY FRAMEWORKS

1.3.1 Population Policy Framework

In 2012, the government of Kenya launched a new policy on population and national development. The policy is described in the Sessional Paper No. 3 of 2012; it outlines the goal of attaining a high quality of life for the people of Kenya by managing population growth to a level that can be sustained with the available resources. The principal objective of the policy is to provide a framework to guide national population programmes and activities for the next two decades (National Council for Population and Development [NCPD], 2012). Overall, the policy seeks to:

- Reduce the population growth rate in order to achieve harmony with the economic growth and social development goals envisioned in Vision 2030;
- Reduce fertility and mortality rates and at the same time assist individuals and couples who desire to have children but are unable to;
- Provide equitable and affordable quality reproductive health services, including family planning;
- Contribute to the planning and implementation of socioeconomic development programmes as a long-term measure to influence population dynamics, with a special focus on poverty reduction, technology and research, the environment, education, health and gender equity, and equality and empowerment of women; and
- Mobilise resources through government budgetary allocations, international cooperation, and public/private partnerships to ensure the sustainability of population programmes and significant impacts on population dynamics.

The policy has the following targets:

- Reduce the natural growth rate of the population from 2.5 percent in 2009 to 1.5 percent by 2030.

- Reduce the infant mortality rate from 52 per 1,000 live births in 2009 to 25 per 1,000 live births by 2030.

- Reduce the under-5 mortality rate from 74 per 1,000 live births in 2009 to 48 per 1,000 live births by 2030.

- Reduce the maternal mortality rate from 488 deaths per 100,000 live births in 2009 to 200 deaths per 100,000 live births by 2030.

- Reduce the crude death rate from 13 deaths per 1,000 people in 2009 to 8 deaths per 1000 people by 2030.

- Improve life expectancy at birth for both sexes from 57 years in 2009 to 64 years by 2030.

- Reduce the total fertility rate from 4.6 children per woman in 2009 to 2.6 children per woman by 2030.

1.3.2 Health Priorities and Programmes

The government of Kenya emphasises the health of its citizens and the improvement of health service delivery. The Ministry of Health plays a coordinating and capacity-building role in ensuring that all services offered are in line with established policies and standards. The government recognises that good health is a prerequisite to socioeconomic development. A number of government policy documents and successive national development plans, including Vision 2030, have stated that health services should meet the basic needs of the population, that health facilities should be situated so that they are within reach of all Kenyans, and that there should be a focus on preventive, promotive, and rehabilitative services without ignoring curative services.

Under the 2010 Kenya constitution, the health function has been devolved to the county governments, with distinct functions being assigned to the national and county governments. The national government is responsible for leadership in health policy development, management of national referral health facilities, capacity building and technical assistance to counties, and consumer protection, including the development of norms, standards, and guidelines. The county governments are responsible for county health services and pharmacies; ambulance services; promotion of primary health care; licensing and control of establishments that sell food to the public; cemeteries, funeral parlours, and crematoria; and refuse removal, refuse dumps, and solid waste disposal. With regard to their functions, the county governments have undertaken new strategies and initiatives to address the health needs of their populations, including the construction of more health facilities, the acquisition of new equipment and medication at these facilities, and the addition of ambulances and more medical staff.

The Kenya Health Policy 2014-2030 takes into account the objectives of devolution and adheres to the following principles:

- Equity in the distribution of health services and interventions;
- A people-centred approach to health and health interventions;
- A participatory approach to delivery of interventions;
- A multisectoral approach to realising health goals;
- Efficiency in the application of health technologies; and
- Social accountability.

1.4 OBJECTIVES OF THE SURVEY

The 2014 Kenya Demographic and Health Survey (KDHS) was designed to provide information to monitor and evaluate the population and health situations in Kenya and to be a follow-up to the previous

KDHS surveys. In addition, it provides information on indicators previously not collected in KDHS surveys, such as fistula and men's experience of domestic violence. Finally, the 2014 KDHS is the first such survey to provide estimates for selected demographic and health indicators at the county level.

The specific objectives of the 2014 KDHS were to:

- Estimate fertility and childhood, maternal, and adult mortality;
- Measure changes in fertility and contraceptive prevalence;
- Examine basic indicators of maternal and child health;
- Collect anthropometric measures for children and women;
- Describe patterns of knowledge and behaviour related to transmission of HIV and other sexually transmitted infections; and
- Ascertain the extent and pattern of domestic violence and female genital cutting.

1.5 SURVEY ORGANISATION

The 2014 KDHS was a joint effort of many organisations, including the following:

- Kenya National Bureau of Statistics (KNBS)
- Ministry of Health (MOH)
- National AIDS Control Council (NACC)
- National Council for Population and Development (NCPD)
- Kenya Medical Research Institute (KEMRI)
- Ministry of Labour, Social Security and Services
- United States Agency for International Development (USAID/Kenya)
- ICF International
- United Nations Population Fund (UNFPA)
- Department for International Development (DFID)
- World Bank
- Danish International Development Agency (DANIDA)
- United Nations Children's Fund (UNICEF)
- German Development Bank (KfW)
- World Food Programme (WFP)
- Clinton Health Access Initiative (CHAI)
- Micronutrient Initiative (MI)
- U.S. Centers for Disease Control and Prevention (CDC)
- Japan International Cooperation Agency (JICA)
- Joint United Nations Programme on HIV/AIDS (UNAIDS)
- World Health Organization (WHO)

The Kenya National Bureau of Statistics (KNBS) served as the implementing agency and, as such, had a primary role in the planning of the survey and in the analysis and dissemination of the survey results. As the implementing agency, the bureau took responsibility for operational matters including planning and conducting fieldwork and processing collected data. Staff from the KNBS and other partners were responsible for overseeing day-to-day technical operations, including recruitment and training of field and data processing staff and supervision of office and field operations. The bureau was also responsible for organising the writing and distribution of reports. With funding from USAID/Kenya, ICF International staff provided technical assistance, mainly through short-term visits to Kenya, in the areas of survey and sample design, questionnaire design, field staff training, fieldwork monitoring, data processing, and report writing and dissemination. NACC, as the body mandated to coordinate the national HIV and AIDS multisectoral response, assisted in reviewing the protocol and survey instruments to ensure that the information collected is relevant to the national HIV and AIDS programmes. USAID/Kenya provided

funding for survey field transport in addition to other logistical support. WHO-Kenya helped in mobilising logistical and financial support from member organisations. The Ministry of Health (MOH) assisted in reviewing the survey instruments in addition to participating in report writing.

1.6 SAMPLE DESIGN

The sample for the 2014 KDHS was drawn from a master sampling frame, the Fifth National Sample Survey and Evaluation Programme (NASSEP V). This is a frame that the KNBS currently operates to conduct household-based surveys throughout Kenya. Development of the frame began in 2012, and it contains a total of 5,360 clusters split into four equal subsamples. These clusters were drawn with a stratified probability proportional to size sampling methodology from 96,251 enumeration areas (EAs) in the 2009 Kenya Population and Housing Census. The 2014 KDHS used two subsamples of the NASSEP V frame that were developed in 2013. Approximately half of the clusters in these two subsamples were updated between November 2013 and September 2014. Kenya is divided into 47 counties that serve as devolved units of administration, created in the new constitution of 2010. During the development of the NASSEP V, each of the 47 counties was stratified into urban and rural strata; since Nairobi county and Mombasa county have only urban areas, the resulting total was 92 sampling strata.

The 2014 KDHS was designed to produce representative estimates for most of the survey indicators at the national level, for urban and rural areas separately, at the regional (former provincial[1]) level, and for selected indicators at the county level. In order to meet these objectives, the sample was designed to have 40,300 households from 1,612 clusters spread across the country, with 995 clusters in rural areas and 617 in urban areas. Samples were selected independently in each sampling stratum, using a two-stage sample design. In the first stage, the 1,612 EAs were selected with equal probability from the NASSEP V frame. The households from listing operations served as the sampling frame for the second stage of selection, in which 25 households were selected from each cluster.

The interviewers visited only the preselected households, and no replacement of the preselected households was allowed during data collection. The Household Questionnaire and the Woman's Questionnaire were administered in all households, while the Man's Questionnaire was administered in every second household. Because of the non-proportional allocation to the sampling strata and the fixed sample size per cluster, the survey was not self-weighting. The resulting data have, therefore, been weighted to be representative at the national, regional, and county levels.

1.7 QUESTIONNAIRES

The 2014 KDHS used a household questionnaire, a questionnaire for women age 15-49, and a questionnaire for men age 15-54. These instruments were based on the model questionnaires developed for The DHS Program, the questionnaires used in the previous KDHS surveys, and the current information needs of Kenya. During the development of the questionnaires, input was sought from a variety of organisations that are expected to use the resulting data. A two-day workshop involving key stakeholders was held to discuss the questionnaire design.

Producing county-level estimates requires collecting data from a large number of households within each county, resulting in a considerable increase in the sample size from 9,936 households in the 2008-09 KDHS to 40,300 households in 2014. A survey of this magnitude introduces concerns related to data quality and overall management. To address these concerns, reduce the length of fieldwork, and limit interviewer and respondent fatigue, a decision was made to not implement the full questionnaire in every household and, in so doing, to collect only priority indicators at the county level. Stakeholders generated a list of these priority indicators. Short household and woman's questionnaires were then designed based on the full questionnaires; the short questionnaires contain the subset of questions from the full questionnaires required to measure the priority indicators at the county level.

[1] Former provinces were Coast, North Eastern, Eastern, Central, Rift Valley, Western, Nyanza, and Nairobi.

Thus, a total of five questionnaires were used in the 2014 KDHS: (1) a full Household Questionnaire, (2) a short Household Questionnaire, (3) a full Woman's Questionnaire, (4) a short Woman's Questionnaire, and (5) a Man's Questionnaire. The 2014 KDHS sample was divided into halves. In one half, households were administered the full Household Questionnaire, the full Woman's Questionnaire, and the Man's Questionnaire. In the other half, households were administered the short Household Questionnaire and the short Woman's Questionnaire. Selection of these subsamples was done at the household level—within a cluster, one in every two households was selected for the full questionnaires, and the remaining households were selected for the short questionnaires.

It is important to note that the priority data collected in the short questionnaires were collected from all households and from all women since the short questionnaires were subsets of the full questionnaires. Therefore, data collected in both the full and the short questionnaires can produce estimates of indicators at the national, rural/urban, regional, and county levels. Data collected only in the full questionnaires (i.e., in one-half of households) can produce estimates at the national, rural/urban, and regional levels only. Data collected only in the full questionnaires are not recommended for estimation at the county level. A list of topics included in the full and short questionnaires is presented in Appendix E. In this report, county-level data are tabulated for nearly all of the indicators for which they are available; county-level tables are not presented for indicators with insufficient cases for evaluation (less than 50 unweighted cases) within each county. In the case of indicators not collected at the county level, the tables include data at the regional level only.

The Household Questionnaire was used to list all of the usual members of the household and visitors who stayed in the household the night before the survey. One of the main purposes of the Household Questionnaire was to identify women and men who were eligible for the individual interview. Some basic information was collected on the characteristics of each person listed, including age, sex, education, and relationship to the head of the household. The Household Questionnaire also collected information on characteristics of the household's dwelling unit, such as the source of water, type of toilet facilities, materials used for the floor and roof of the house, ownership of various durable goods, and ownership and use of mosquito nets. In addition, this questionnaire was used to record height and weight measurements of women age 15-49 and children under age 5.

The Woman's Questionnaires were used to collect information from women age 15-49. The full questionnaire covered the following topics (see Appendix E for a side-by-side comparison of topics included in the full and short questionnaires):

- Background characteristics (education, marital status, media exposure, etc.)
- Reproductive history
- Knowledge and use of family planning methods
- Fertility preferences
- Antenatal and delivery care
- Breastfeeding and infant feeding practices
- Vaccinations and childhood illnesses
- Marriage and sexual activity
- Women's work and husbands' background characteristics
- Childhood mortality
- Awareness and behaviour regarding HIV and other sexually transmitted infections
- Adult mortality, including maternal mortality
- Domestic violence
- Female circumcision
- Fistula

The Man's Questionnaire was administered to men age 15-54 living in every second household in the sample. The Man's Questionnaire collected information similar to that contained in the Woman's Questionnaire but was shorter because it did not contain questions on maternal and child health, nutrition, adult and maternal mortality, or experience of female circumcision or fistula.

Both the Woman's and the Man's Questionnaires also included a series of questions to obtain information on respondents' experience of domestic violence. The domestic violence questions were administered in the subsample of households that received the full Household Questionnaire, the full Woman's Questionnaire, and the Man's Questionnaire. Additionally, the violence questions were administered to only one eligible individual, a woman or a man, per household. In households with more than one eligible individual, special procedures were followed in order to ensure that there was random selection of the respondent to be interviewed for the domestic violence module.

After finalisation of the questionnaires in English, they were translated into 16 other languages, namely Borana, Embu, Kalenjin, Kamba, Kikuyu, Kisii, Luhya, Luo, Maasai, Maragoli, Meru, Mijikenda, Pokot, Somali, Swahili, and Turkana. The translated questionnaires were pretested to detect any possible problems in questionnaire translation or flow, as well as to gauge the length of time required for interviews.

1.8 TRAINING

1.8.1 Training of Trainers

Training of trainers was conducted by ICF International from January 20-25, 2014, with 18 trainers drawn from the KNBS and the Ministry of Health. The objectives of the training were to harmonise concepts related to survey design and questionnaire content, to review effective adult teaching techniques, and to familiarise trainers with the training materials and equipment. The trainers participated in leading the pretest and the main training and later served as fieldwork coordinators during data collection.

1.8.2 Pretest Activities

The pretest took place from January 17 to February 15, 2014. The objectives of the pretest were (1) to train interviewers, editors, and supervisors to fulfil their respective roles and to conduct high-quality household and individual interviews, (2) to pilot the questionnaires in the field, and (3) to review and modify the questionnaire translations based on field experience. Classroom training addressed all aspects of the questionnaire content and interviewing procedures and included anthropometry practice with children from neighbouring child care centres. Training concluded with two days of local field practice, after which field teams were formed and sent throughout Kenya (to clusters not included in the KDHS sample) to pilot the translated questionnaires. After the fieldwork, a two-day debriefing workshop was held to look at the issues emanating from the pretest. The resolutions from the debriefing were used to enrich the questionnaires and improve field logistics before implementation of the main training and the actual survey.

1.8.3 Main Training of Field Staff

Several categories of personnel were recruited and trained to undertake the 2014 KDHS. These included 48 supervisors, 48 field editors, 144 female interviewers, 48 male interviewers, 28 quality assurance personnel, and 20 reserves.

The training for these personnel took place from March 24 to April 17, 2014, in Nakuru. Trainees were divided into six classrooms, each managed by three trainers. The training consisted of a detailed, question-by-question explanation of the questionnaires, accompanied by explanations from the interviewer's manual, demonstration through role-plays, group discussions, and in-class practice

interviewing in pairs. Several graded take-home assignments and quizzes were administered, the results of which were used both to enhance understanding of key terms and concepts and to identify candidates for further strengthening or elimination from the field teams. A number of guest speakers were invited to give lectures on specific topics relevant to the KDHS.

Anthropometry training provided all trainees with instruction, demonstration, and practice in length/height and weight measurements for children and adults. Trainees completed a standardisation exercise measuring children, intended to gauge and improve measurement accuracy and precision. In this exercise, 175 children age 0-59 months and their caregivers were invited to the training site in groups of 50 child-caregiver pairs assigned throughout the day to one of three classrooms. Fifteen nutrition specialists from partnering organisations were trained to support the exercise; they provided a reference measurement for children and monitored the standardisation activity. Each of the 336 trainees served as both measurers and assistants and measured the same 10 children twice. Results were recorded and analysed using Software for Emergency Nutrition Assessment (ENA for SMART); more than 70 percent of trainees' scores were acceptable or higher. A debriefing session was held the following day to provide feedback and correction to trainees.

Three field practice sessions were held throughout the main training. Trainees were organised into teams with a team leader selected from the pretest trainees. Team leaders assisted with logistics, guided trainees through fieldwork, monitored trainees' performance, edited trainees' questionnaires for errors, and debriefed their team on errors/corrections. The first field practice occurred early in the training and focused only on the Household Questionnaire. The final two days of field practice occurred at the end of training and covered the full KDHS protocol: all questionnaires, salt testing, and anthropometry.

1.9 FIELDWORK

Fieldwork for the main survey took place from May 7 to October 20, 2014. Field staff were divided into 48 teams according to counties and languages spoken in the areas where they conducted the interviews. Each team had one supervisor, one field editor, three female interviewers, one male interviewer, a driver, and a vehicle. Data collection was overseen by 18 coordinators who had also served as trainers during the pretest and main training and by a staff of 28 quality assurance personnel. Coordinators were each assigned two to three teams for which they were responsible for observing and monitoring data collection quality, ensuring uniformity in data collection procedures and fidelity to the survey protocol, providing moral support to the field teams, and replenishing field team supplies. Coordinators met in person and via phone with teams throughout the fieldwork, spending a total of 70 days in the field. Quality control staff fulfilled similar responsibilities and spent a total of 60 days in the field.

1.10 DATA PROCESSING

Completed questionnaires were sent to the KNBS Data Processing Centre in Nairobi. Office editors who received the questionnaires verified cluster and household numbers to ensure that they were consistent with the sampled list. They also ensured that each cluster had 25 households and that all questionnaires for a particular household were packaged together.

Data entry began on May 28, 2014, with a four-day training session and continued until November 21, 2014. All data were double entered (100 percent verification) using CSPro software. The data processing team included 42 keyers, three office editors, two secondary editors, four supervisors, and one data manager. Secondary editing, which included further data cleaning and validation, ran simultaneously with data entry and was completed on January 28, 2015, in collaboration with ICF International. The KDHS Key Indicators Report was prepared and launched in April 2015.

1.11 RESPONSE RATES

Table 1.2 presents the summary response rates for the 2014 KDHS. A total of 39,679 households were selected for the sample, of which 36,812 were found occupied at the time of the fieldwork. Of these households, 36,430 were successfully interviewed, yielding an overall household response rate of 99 percent. The shortfall of households occupied was primarily due to structures that were found to be vacant or destroyed and households that were absent for an extended period of time.

Table 1.2 Results of the household and individual interviews

Number of households, number of interviews, and response rates, according to residence (unweighted), Kenya 2014

Result	Residence		Total
	Urban	Rural	
ALL HOUSEHOLDS

Eligible women response rate[2]	96.2	97.4	96.9

[1] Households interviewed/households occupied
[2] Respondents interviewed/eligible respondents

As noted, the 2014 KDHS sample was divided into halves, with one half of households receiving the full Household Questionnaire, the full Woman's Questionnaire, and the Man's Questionnaire and the other half receiving the short Household Questionnaire and the short Woman's Questionnaire. The household response rate for the full Household Questionnaire was 99 percent, as was the household response rate for the short Household Questionnaire.

In the households selected for and interviewed using the full questionnaires, a total of 15,317 women were identified as eligible for the full Woman's Questionnaire, of whom 14,741 were interviewed, generating a response rate of 96 percent. A total of 14,217 men were identified as eligible in these households, of whom 12,819 were successfully interviewed, generating a response rate of 90 percent.

In the households selected for and interviewed with the short questionnaires, a total of 16,855 women were identified as eligible for the short Woman's Questionnaire, of whom 16,338 were interviewed, yielding a response rate of 97 percent.

Response rates are lower in the urban sample than in the rural sample, more so for men. The principal reason for non-response among both eligible men and eligible women was failure to find them at home despite repeated visits to the household. The lower response rates for men reflect the more frequent and longer absences of men from the household.

HOUSING CHARACTERISTICS AND HOUSEHOLD POPULATION

2

Macdonald Obudho, James N. Munguti, John K. Bore, Mutua Kakinyi

Key Findings

- The majority (71 percent) of households in Kenya have access to an improved source of drinking water.
- Twenty-three percent of households have an improved toilet facility that is not shared with other households.
- The majority (64 percent) of households in Kenya do not have electricity.
- Almost half (46 percent) of households live in dwellings with cement floors.
- More than half (53 percent) of households use one room for sleeping.
- More than half (56 percent) of households use wood as their main source of cooking fuel.
- Eighty-six percent of households own mobile phones.
- Three in 10 Kenyans are below age 10.
- One-third of households are headed by women.
- The average household size in Kenya is 3.9 members.
- The births of two out of every three children below age 5 are registered with the civil authorities.

This chapter provides an overview of the demographic and socioeconomic characteristics of the households sampled in the 2014 KDHS. In the 2014 KDHS, a household is defined as a person or group of persons, related or unrelated, who usually live together, who acknowledge one adult member as the head of the household, and who have common cooking arrangements. Information was collected on all usual residents of a selected household (de jure population) as well as persons who had stayed in the selected household the night before the interview (de facto population).

This chapter presents information on the conditions of the households in which the survey population lives, including the source of drinking water, availability of electricity, sanitation facilities, building materials, and possession of household durable goods. Also included are findings on birth registration among children, living arrangements, orphanhood status, school attendance, and educational attainment. The background information presented in this chapter is intended to facilitate the interpretation of the demographic, socioeconomic, and health indices presented in later chapters.

2.1 HOUSEHOLD CHARACTERISTICS

The characteristics of a household determine the socioeconomic and health status of its members. The household is where decisions about health, education, and general welfare are made and acted upon. The 2014 KDHS asked respondents about their household environment, including the source of drinking water; type of sanitation facility; building characteristics such as type of material used for the roofing, flooring, and walls; and number of rooms used for sleeping. Many of these measures help to assess Kenya's progress towards Millennium Development Goal 7, which focuses on environmental sustainability and targets sustainable access to safe drinking water, basic sanitation, and adequate housing.

2.1.1 Water and Sanitation

Table 2.1 includes a number of indicators that are useful in monitoring household access to improved drinking water. Improved water sources include piped water into the dwelling, yard, or plot; a public tap/standpipe or borehole; a protected well or protected spring water; rainwater; and bottled water. Lack of easy access to an improved water source may limit the quantity of suitable drinking water that is available to a household as well as increase the risk of illness. Unimproved water sources increase the spread of waterborne disease and the burden of service delivery through increased demand for health care; these sources include unprotected wells or springs, water delivered by tanker trucks, and surface water.

Table 2.1 Household drinking water

Percent distribution of households and de jure population by source of drinking water, time to obtain drinking water, treatment of drinking water, and person who usually collects drinking water, according to residence, Kenya 2014

Number of households selected for full questionnaire	7,280	10,080	17,360	23,176	44,073	67,249

Note: Totals may not add up to 100 percent because households with missing information are not shown separately.
[1] Respondents may report multiple treatment methods; therefore, the sum of all treatment methods may exceed 100 percent.
[2] Other water treatment methods include covering the water container, and letting the water stand and settle.
[3] Appropriate water treatment methods include boiling, bleaching/adding chlorine, filtering/straining, and solar disinfecting.

Table 2.1 indicates that the majority of households in Kenya (71 percent) obtain drinking water from an improved source, while 27 percent use non-improved sources. This is an improvement since the 2008-09 KDHS, when 63 percent of households obtained drinking water from an improved source. Use of improved sources is more common among households in urban areas (88 percent) than among those in rural areas (59 percent). The most common source of drinking water in urban areas is water piped into the dwelling/yard/plot, with almost half (46 percent) of households using this source. In rural areas, the most common source of drinking water is surface water (24 percent), followed by water piped into the dwelling/yard/plot (15 percent).

Nearly 4 in 10 households have the source for their drinking water on their premises, but nearly 3 in 10 households (28 percent) spend 30 minutes or longer to obtain their drinking water. In rural areas, 4 in 10 households spend 30 minutes or more to obtain their drinking water, as compared with only 1 in 10 urban households.

Over half of households (54 percent) do not treat their drinking water, and this is true in both urban and rural areas. The most commonly used methods of water treatment are boiling and adding bleach/chlorine (24 percent and 22 percent of households, respectively). Overall, 45 percent of households use an appropriate treatment method.

When water is not on the premises, the responsibility of collecting drinking water usually rests on adult women. Forty-five percent of households reported that a female adult age 15 and above usually collects the drinking water for the household. An even higher percentage of rural households delegate collection of drinking water to women (57 percent), as these households are much less likely to have their water source on the premises.

Table 2.2 presents the percent distribution of households and the de jure population by the type of toilet/latrine facilities usually used by household members. Twenty-five percent of household members usually use an improved (and not shared) toilet/latrine facility. About 4 in 10 urban dwellers (43 percent) use an improved facility that is shared by two or more households, as compared with only about 1 in 10 (12 percent) rural dwellers. Approximately two-thirds of rural Kenyans usually use a non-improved toilet facility (66 percent), most commonly a pit latrine without a slab or an open pit (48 percent). One-half of urban Kenyans use a shared facility of which a pit latrine with a slab is the most common (17 percent).

Table 2.2 Household sanitation facilities

Percent distribution of households and de jure population by type of toilet/latrine facilities, according to residence, Kenya 2014

Note: Totals may not add up to 100 percent because households with missing information are not shown separately.
[1] Facilities that would be considered improved if they were not shared by two or more households.

2.1.2 Housing Characteristics

Table 2.3 presents information on housing characteristics in Kenya. These characteristics are usually a function of the household's socioeconomic situation and have a direct bearing on the health and welfare of household members. The table includes information on access to electricity, type of flooring material, number of rooms used for sleeping, the place used for cooking, the type of fuel used for cooking, and the frequency of someone smoking in the home. The majority of households in urban areas have electricity (68 percent), while the vast majority of rural households do not (only 13 percent have electricity). Nationally, 36 percent of households have access to electricity, as compared with 23 percent in 2008-09.

Cement is the most common household flooring material; 46 percent of households have cement floors, up from 41 percent in 2008-09. Not surprisingly, cement floors are much more common in urban households (70 percent) than in rural households (28 percent). The most common flooring in rural households is earth/sand (43 percent).

The number of rooms used for sleeping provides an indication of the extent of crowding in households. Overcrowding increases the risk of contracting infectious diseases such as acute respiratory infections and skin diseases, which particularly affect children and the elderly population. The proportion of households using one room for sleeping has increased from 48 percent to 53 percent in the last five years. The presence and extent of indoor pollution are dependent on cooking practices, the cooking location, and types of fuel used. According to the 2014 KDHS, 50 percent of households cook inside the

home, while 42 percent cook in a separate building and 7 percent cook outdoors. The percentage of households that cook within the dwelling unit is much higher in urban areas (77 percent) than in rural areas (30 percent). Using solid fuels for cooking increases indoor pollution. Solid fuels are defined as coal/lignite, charcoal, wood, straw/shrubs/grass, and agricultural crops. Nationally, 75 percent of households use solid fuels, mostly wood (56 percent) and charcoal (17 percent). While this is a decrease

from the 84 percent of households using solid fuels reported in the 2008-09 KDHS, over 9 in 10 rural households continue to use solid fuels. Households that do not use solid fuels mostly use gas or kerosene (12 percent of households each, compared with 7 percent and 8 percent, respectively in 2008-09).

A major concern for the government of Kenya is the effect of secondhand smoke on the health of children and neonates. The purpose of the Tobacco Control Act of 2007, followed in 2014 by the Tobacco Control Regulations (2014), is to control tobacco and tobacco-related product use. Secondhand smoke is a risk factor for children and adults who do not smoke. Children who are exposed to secondhand smoke are at a higher risk of respiratory and ear infections and poor lung development (U.S. Department of Health and Human Services, 2006). Pregnant women who are exposed to secondhand smoke have a higher risk of giving birth to a low birth weight baby (Windham et al., 1999). To measure the extent of smoke exposure among household members, respondents were asked how often anyone smokes inside the house. In Kenya, someone smokes in the house on a daily basis in 12 percent of households (11 percent in urban areas and 13 percent in rural areas).

2.1.3 Household Possessions

The availability of durable consumer goods is a useful indicator of a household's socioeconomic status. Moreover, particular goods have specific benefits. For instance, having access to a radio or a television exposes household members to innovative ideas; a refrigerator prolongs the wholesomeness of foods; and a means of transport allows greater access to services away from the local area. Table 2.4 shows the availability of selected consumer goods by residence.

Table 2.4 Household possessions

[1] Local cattle, exotic/grade cattle, horses, donkeys, camels, goats, sheep or chickens

Possession of mobile phones has significantly increased from 62 percent in 2008-09 to 86 percent in 2014; rural areas have registered a greater increase (from 53 percent to 80 percent), as ownership of mobile phones among urban households was already relatively high. More than 9 in 10 urban households (94 percent) own a mobile phone. Sixty-eight percent of households have a radio, and about one-third (35 percent) have a television. Urban households are somewhat more likely to possess a radio (74 percent) than rural households (63 percent). Fifty-six percent of urban households and 19 percent of rural households possess a television, and television ownership has increased nationally from 28 percent to 35 percent since 2008-09. A refrigerator is available in 13 percent of urban households and only 2 percent of rural households.

Bicycles are still the most common means of transport owned by households. Twenty-one percent of households own a bicycle (25 percent in rural areas and 16 percent in urban areas).

The agricultural sector plays a large role in the Kenyan economy, and a substantial proportion of the population is engaged in this sector. The 2014 KDHS indicates that two of every three households own agricultural land, with 79 percent of rural households and 48 percent of urban households owning land. Two in three households (65 percent) own farm animals, 80 percent in rural areas and 43 percent in urban areas. In urban areas, ownership of agricultural land and farm animals has increased since 2008-09 (from 35 percent to 48 percent and 27 percent to 43 percent, respectively), while the national figure has remained at two-thirds.

More than 8 in 10 rural households own their dwelling (85 percent) and the land on which the dwelling is built (82 percent). About one-quarter (26 percent) of urban households own their dwelling and the land on which it is built (24 percent). Thus, nationally, 6 in 10 Kenyan households own their dwelling (60 percent), and nearly 6 in 10 (58 percent) own the land on which the dwelling is built.

2.2 HOUSEHOLD WEALTH

The wealth index used in this report and in many other DHS survey reports serves as a proxy for a household's long-term standard of living. It has been demonstrated to be consistent with expenditure and income measures (Rutstein, 1999; Rutstein and Johnson, 2004). The index is constructed using household asset data collected in the Household Questionnaire and is generated via a principal components analysis.

The wealth index has been improved to better take into account urban-rural differences in scores and indicators of wealth by performing the first and second steps of its creation separately for urban and rural areas prior to creating a national wealth index in the last step. In the first step, a subset of indicators common to urban and rural areas is used to create wealth scores for households in both areas. Categorical variables to be used are transformed into separate dichotomous (0-1) indicators. These indicators and those that are continuous are then examined using a principal components analysis to produce a common factor score for each household. In the second step, separate factor scores are produced for households in urban and rural areas using area-specific indicators. The third step combines the separate area-specific factor scores to produce a nationally applicable combined wealth index by adjusting area-specific scores through a regression on the common factor scores. The resulting combined wealth index has a mean of zero and a standard deviation of one. Once the index is computed, national-level wealth quintiles (from lowest to highest) are obtained by assigning the household score to each de jure household member, ranking each person in the population by his or her score, and then dividing the ranking into five equal categories, each comprising 20 percent of the population.

Thus, throughout this report, wealth quintiles are expressed in terms of quintiles of individuals in the overall population rather than quintiles of individuals at risk for any one health or population indicator. For example, quintile rates for infant mortality refer to infant mortality rates per 1,000 live births among all people in the population quintile concerned, as distinct from quintiles of live births or newly born infants, who constitute the only members of the population at risk of mortality during infancy.

Table 2.5 presents percent distributions of the de jure population across the five wealth quintiles by residence and region. Three-quarters of urban residents (75 percent) are in the two highest wealth quintiles, while more than three-quarters of rural residents (78 percent) are in the lowest three quintiles (and are nearly equally distributed across these quintiles). By region, the most skewed distributions are seen in Nairobi and North Eastern. Nine in 10 people in Nairobi are in the two highest wealth quintiles, and 7 in 10 people in North Eastern are in the lowest wealth quintile. Populations in the other regions are more spread out across the quintiles.

Table 2.5 Wealth quintiles

Percent distribution of the de jure population by wealth quintiles, and the Gini Coefficient, according to residence and region, Kenya 2014

Residence/ region/county	Wealth quintile					Total	Number of persons	Gini coefficient
	Lowest	Second	Middle	Fourth	Highest			
Residence								
Urban	6.0	8.3	10.6	26.1	49.0	100.0	48,946	0.18
Rural	27.3	26.1	24.9	16.8	4.9	100.0	93,762	0.19
Region								
Coast	40.0	10.4	10.6	14.5	24.5	100.0	13,972	0.34
North Eastern	72.9	4.5	4.5	9.0	9.1	100.0	4,164	0.36
Eastern	19.5	27.7	22.4	19.7	10.7	100.0	20,960	0.21
Central	2.4	12.0	21.9	32.0	31.7	100.0	16,297	0.21
Rift Valley	26.5	20.2	19.7	19.1	14.5	100.0	37,746	0.29
Western	12.3	30.9	33.8	16.8	6.2	100.0	16,692	0.20
Nyanza	16.6	31.2	23.8	17.5	10.9	100.0	20,050	0.28
Nairobi	0.2	0.8	6.0	25.6	67.4	100.0	12,827	0.15
Total	20.0	20.0	20.0	20.0	20.0	100.0	142,708	0.27

Table 2.5 also includes information on the Gini coefficient, which indicates the level of concentration of wealth (0 being an equal distribution and 1 a totally unequal distribution). This ratio is expressed as a proportion between 0 and 1. The coefficient indicates the distribution of wealth independent of the level of wealth. The coefficient is lowest in Nairobi, indicating that people in that region are more similar to each other with regard to wealth than people in any other region. With the highest Gini coefficient of 0.36, the most unequal distribution of wealth is seen in the North Eastern region.

2.3 FOOD SECURITY

The National Food and Nutrition Security Policy of 2011 states that all Kenyans should at all times have access to safe food of sufficient quantity and quality to satisfy their nutritional needs for optimal health. Household respondents in the 2014 KDHS were asked on how many days during the seven days preceding the survey members of their household had consumed items from various food groups (staples, pulses, vegetables, fruits, meat, dairy, oil, and sugar). They were also asked if there were any days in the seven days preceding the survey when their household did not have food or enough money to buy food. Respondents who answered 'yes' to the latter question were asked to indicate how many days in that week their household had to rely on less preferred food, rely on borrowed food, reduce the number of meals, reduce the size of meals, and/or reduce what adults ate in order for small children to eat. These questions and the three measures described below were developed by the World Food Programme.

The first measure, the food consumption score (FCS), derived from the household consumption history questions, is a composite calculation including dietary diversity (the number of food groups consumed by a household over a seven-day period), food frequency (the number of days a particular food group is consumed), and the relative nutritional importance of different food groups. The FCS is intended to describe short-term food security at the time of data collection. Food consumption scores are divided into poor, borderline, and acceptable food consumption groups.

The second measure is the percentage of households that report lacking food or money to purchase food in the seven days preceding the survey. The third measure is the coping strategy index (CSI). The CSI is a composite calculation of the frequency and severity of coping strategies that households adopt when facing lack of food or money to purchase food. A higher CSI score indicates a more serious food security

situation. The minimum possible CSI score (among households reporting any of the provided list of coping strategies) is 7.0, and the maximum possible score is 56.0.

Table 2.6 presents the percent distribution of households with poor, borderline, or acceptable food consumption; the percentage of households that report lacking food or money to purchase food; and the mean CSI score, according to background characteristics.

Table 2.6 Food security status

Percent distribution of households with poor, borderline or acceptable food consumption, percentage of households that report lacking food or money to purchase food in the seven days preceding the survey, and the mean coping strategy index, according to background characteristics, Kenya 2014

Background characteristic	Food consumption score groups			Total	Number of households with valid food consumption score	Percentage of households that report lacking food or money to purchase food	Number of households	Mean coping strategy index	Number of households with total coping strategy index greater than zero
	Poor	Borderline	Acceptable						
Residence									
Urban	1.4	7.3	91.3	100.0	7,217	23.0	7,280	17.4	1,658

Region									
Coast	1.1	10.7	88.2	100.0	1,651	24.5	1,688	16.1	414
North Eastern	1.9	8.5	89.6	100.0	342	37.8	344	15.4	130
Eastern	0.8	8.0	91.2	100.0	2,510	37.5	2,516	20.0	942
Central	1.3	5.8	92.9	100.0	2,391	17.4	2,400	16.7	418
Rift Valley	2.3	11.4	86.4	100.0	4,387	25.4	4,406	22.1	1,119
Western	1.4	10.8	87.8	100.0	1,720	44.6	1,726	17.3	769
Nyanza	1.6	12.9	85.5	100.0	2,174	41.9	2,187	18.4	915
Nairobi	1.6	7.5	90.8	100.0	2,085	29.1	2,093	18.3	597
Wealth quintile									
Lowest	3.8	17.9	78.3	100.0	2,888	54.4	2,894	21.7	1,574
Second	1.8	14.0	84.2	100.0	3,152	41.6	3,166	19.5	1,316
Middle	1.1	9.8	89.1	100.0	3,244	32.6	3,262	17.4	1,061
Fourth	0.8	6.2	93.0	100.0	3,913	21.1	3,948	16.3	824
Highest	0.8	3.7	95.5	100.0	4,062	13.0	4,091	16.1	528
Total	1.5	9.7	88.8	100.0	17,258	30.7	17,360	18.9	5,303

Note: The food consumption score reflects the quantity and quality of people's diet. The coping strategy index measures behaviours adopted by households when they have difficulties in covering their food needs.

The majority of households (89 percent) in Kenya had acceptable food consumption scores. Two percent of households had poor food consumption scores and 10 percent had borderline scores. Rural households were more likely to have borderline scores (11 percent) than urban households (7 percent). Households in Nyanza were most likely (13 percent) to have borderline scores, followed closely by households in Rift Valley, Western, and Coast (all 11 percent). The proportion of households with borderline scores decreased with increasing household wealth.

Three in 10 (31 percent) households in Kenya reported not having enough food or money to buy food in the seven days preceding the survey. More than 3 in 10 rural households (36 percent) and households in Western (45 percent), Nyanza (42 percent), North Eastern (38 percent), and Eastern (38 percent) reported lacking food or money to purchase food. As expected, the likelihood of lacking food or money to purchase food decreased with increasing household wealth. However, 13 percent of households in the highest wealth quintile did report not having enough food or money to buy food.

Among households that reported not having food or enough money to purchase food, the mean CSI score was 18.9. The mean score was highest in Rift Valley (22.1) and lowest in North Eastern (15.4). Mean CSI scores decreased slightly with increasing household wealth.

2.4 HAND WASHING

Environmental management at the household level is a key indicator of a household's intention to manage its health. Hand washing is one of the most effective ways to prevent the spread of germs, and it is used here as an indicator of personal and household hygiene. Table 2.7 provides information on places designated for hand washing and the availability of water and cleansing agents by residence, region, and wealth quintile.

Table 2.7 Hand washing

Percentage of households in which the place most often used for washing hands was observed, and among households in which the place for washing hands was observed, percent distribution by availability of water, soap and other cleansing agents, Kenya 2014

Background characteristic	Percentage of households where place for washing hands was observed	Number of households	Among households where place for washing hands was observed, percentage with:							Number of households with place for washing hands was observed
			Soap and water[1]	Water and cleansing agent[2] other than soap only	Water only	Soap but no water[3]	Cleansing agent other than soap only[2]	No water, no soap, no other cleansing agent	Total	
Residence

Wealth quintile										
Lowest	18.0	2,894	18.5	0.6	18.8	2.7	0.0	59.0	100.0	520
Second	24.8	3,166	33.2	0.1	20.8	3.7	0.3	41.5	100.0	784
Middle	27.9	3,262	40.7	0.0	23.4	3.7	0.0	31.8	100.0	911
Fourth	36.6	3,948	48.5	0.0	30.6	2.9	0.0	17.9	100.0	1,445
Highest	53.3	4,091	67.2	0.3	21.7	3.0	0.0	7.7	100.0	2,180
Total	33.6	17,360	49.5	0.2	23.8	3.2	0.0	23.1	100.0	5,840

Note: Totals may not add up to 100 percent because households with missing information are not shown separately.
[1] Soap includes soap or detergent in bar, liquid, powder or paste form. This column includes households with soap and water only as well as those that had soap and water and another cleansing agent.
[2] Cleansing agents other than soap include locally available materials such as ash, mud or sand.
[3] Includes households with soap only as well as those with soap and another cleansing agent

Interviewers collected data by observing the place household members use for hand washing. A place for handwashing was only observed in one-third of households. A place for hand washing was observed in about 4 in 10 urban households (43 percent) and fewer than 3 in 10 rural households (27 percent). The ability of interviewers to observe a place for hand washing varied substantially across regions, from a low of 17 percent in Nyanza to a high of 56 percent in Central. It is especially interesting to note that the ability of interviewers to observe a place for hand washing steadily increased with increasing wealth, from a low of only 18 percent among households in the lowest quintile to a high of 53 percent observed among households in the highest quintile.

Both water and soap were available in 50 percent of the households where a place for hand washing was observed (60 percent of urban households and 38 percent of rural households). The presence of soap and water increases steadily with increasing wealth, from 19 percent in the lowest quintile to 67 percent in the highest quintile. Approximately half of households in Coast, North Eastern, and Western where a place for hand washing was observed had neither water nor soap available.

2.5 HOUSEHOLD POPULATION BY AGE AND SEX

The distribution of the de facto household population in the 2014 KDHS is shown in Table 2.8 by five-year age groups, according to sex and residence. The age and sex structure of the population is key in all demographic analyses. The 2014 KDHS de facto household population constitutes 137,780 persons, of whom 51 percent are female and 49 percent are male. Among this population, 34 percent live in urban areas and 66 live in rural areas. Half of the population is below age 20 (52 percent). At 14 percent, the under-5 population constitutes the largest age group in urban areas, while the 5-9 population is the largest five-year age group in rural areas (17 percent).

Table 2.8 Household population by age, sex, and residence

Percent distribution of the de facto household population by five-year age groups, according to sex and residence, Kenya 2014

	Urban			Rural			Total		
Age	Male	Female	Total	Male	Female	Total	Male	Female	Total
<5	13.8	13.9	13.9	15.6	13.9	14.7	15.0	13.9	14.4
5-9	12.6	12.5	12.5	17.4	16.3	16.8	15.7	15.0	15.3

Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0
Number	23,574	23,871	47,445	43,865	46,470	90,335	67,439	70,341	137,780

Figure 2.1 depicts the age-sex structure of the Kenyan population in a population pyramid. The broad base depicts the youthfulness of the population. The drop in the female population between ages 10-14 and 15-19 is a bit steep and could partially be due to some interviewers estimating ages of women to be under the interview cutoff age of 15 to reduce their workload. Similarly, there is an increase in the female population between ages 45-49 and 50-54, which might be due to pushing some of the women out of the age eligibility category. The drop in population between ages 5-9 and under 5 among both males and females reflects a fertility decline, addressed in the chapter on fertility.

Figure 2.1 **Population pyramid**

2.6 HOUSEHOLD COMPOSITION

Information on key aspects of the composition of households is presented in Table 2.9. Nationally, one-third of households are headed by women. A higher proportion of rural than urban households are headed by women (36 percent and 27 percent, respectively).

Table 2.9 Household composition

Percent distribution of households by sex of head of household and by household size; mean size of household, and percentage of households with orphans and foster children under 18 years of age, according to residence, Kenya 2014

Characteristic	Residence		Total
	Urban	Rural	
Household headship			
Male	72.7	64.2	67.8
Female	27.3	35.8	32.2
Total	100.0	100.0	100.0
Number of usual members			
0	0.1	0.0	0.0
1	27.3	13.5	19.3
2	16.6	10.2	12.9
3	16.5	14.1	15.1
4	15.6	17.0	16.4
5	10.7	15.2	13.3
6	6.1	10.9	8.8
7	3.4	7.8	6.0
8	1.8	5.2	3.8
9+	1.9	6.2	4.4
Total	100.0	100.0	100.0
Mean size of households	3.2	4.4	3.9
Percentage of households with orphans and foster children under 18 years of age			
Foster children[1]	10.8	21.3	16.9
Double orphans	1.3	1.9	1.6
Single orphans[2]	5.4	10.8	8.5
Foster and/or orphan children	13.5	26.4	21.0
Number of households	15,290	21,140	36,430

Note: Table is based on de jure household members, i.e., usual residents.
[1] Foster children are those under age 18 living in households with neither their mother nor their father present.
[2] Includes children with one dead parent and an unknown survival status of the other parent.

The data also show that the mean size of a Kenyan household is 3.9 people, lower than the mean size of 4.2 recorded in the 2008-09 KDHS. As expected, rural households are larger on average (4.4 people) than urban households (3.2 people).

Nationally, 17 percent of Kenyan households are fostering a child under age 18 (1 in every 10 urban households and 2 in every 10 rural households). Nine percent of all Kenyan children under age 18 have had one parent die. The percentage of households housing a single or double orphan is higher in rural areas (13 percent) than in urban areas (7 percent).

2.7 BIRTH REGISTRATION

Birth registration is the inscription of the facts of the birth into an official log kept at the registrar's office. A birth certificate is issued at the time of registration or later as proof of the registration of the birth. Birth registration is basic to ensuring a child's legal status and, thus, basic rights and services.

Table 2.10 presents the percentage of the de jure population under age 5 whose births are registered with the civil authorities, according to background characteristics. Two-thirds of children in Kenya have their births registered (67 percent). This is an improvement of 7 percentage points since the 2008-09 KDHS, which reported a figure of 60 percent. However, only about one-quarter (24 percent) of children are reported to have a birth certificate.

Table 2.10 Birth registration of children under age five

Percentage of de jure children under five years of age whose births are registered with the civil authorities, according to background characteristics, Kenya 2014

Background characteristic	Children whose births are registered			Number of children
	Percentage who had a birth certificate	Percentage who did not have birth certificate	Percentage registered	
Age				
<2	19.8	48.2	68.0	7,662
2-4	26.8	39.4	66.2	12,291
Sex				
Male	24.9	42.5	67.4	10,170
Female	23.3	43.1	66.4	9,784
Residence				
Urban	37.4	41.4	78.8	6,603
Rural	17.5	43.4	61.0	13,351
Region				
Coast	21.3	53.5	74.8	2,019
North Eastern	44.7	17.1	61.8	682
Eastern	18.1	57.0	75.1	2,458
Central	36.3	53.4	89.7	1,789
Rift Valley	20.1	42.8	62.9	5,727
Western	19.6	33.6	53.2	2,585
Nyanza	19.5	34.6	54.1	2,929
Nairobi	42.6	36.9	79.5	1,765
Wealth quintile				
Lowest	12.3	39.8	52.1	4,924
Second	15.4	43.2	58.6	4,277
Middle	19.7	45.4	65.0	3,652
Fourth	27.5	49.6	77.1	3,430
Highest	51.4	37.3	88.7	3,670
Total	24.1	42.8	66.9	19,954

There is little age or sex differential nationally in the percentage of children registered. However, only slightly more than half of children in Western and Nyanza are registered, as compared with 9 in 10 children in Central. The percentage of children registered and the percentage having a birth certificate both increase steadily with increasing wealth.

2.8 CHILDREN'S LIVING ARRANGEMENTS, ORPHANHOOD, AND SCHOOL ATTENDANCE

Children's living arrangements affect their development and well-being. Table 2.11 presents the percent distribution of children by their living arrangements and the survival status of their biological parents. For 22 percent of children, both parents are alive but their father is living elsewhere; 10 percent of children are not living with either parent although both are alive.

There is not a great deal of variation in living arrangements by sex of the child. Children in urban areas are slightly more likely to be living with both parents (59 percent) than children in rural areas (53 percent).

Nationally, only 55 percent of children age 0-17 live with both of their biological parents and living arrangements vary by region. Two-thirds of children in Nairobi are living with both of their parents, the highest percentage in the country, while only half of children in the Eastern and Western regions are living with both parents. Children in the Western region are most likely (16 percent) to not be living with either parent despite both of them being alive. Nyanza has the highest percentage of children who have experienced the death of their father; 9 percent of these children are living with their mother, and 3 percent are living with neither parent. Children in the Eastern region are most likely to be living with their mother but not their father even though their father is alive (28 percent).

A notable pattern by wealth quintile is seen among children living with their mother but not their father. The percentage of children who are living with their mother and whose father has died decreases with increasing wealth.

Table 2.11 Children's living arrangements and orphanhood

Percent distribution of de jure children under age 18 by living arrangements and survival status of parents, the percentage of children not living with a biological parent, and the percentage of children with one or both parents dead, according to background characteristics, Kenya 2014

Background characteristic	Living with both parents	Living with mother but not with father		Living with father but not with mother		Not living with either parent					Total	Percentage not living with a biological parent	Percentage with one or both parents dead[1]	Number of children
		Father alive	Father dead	Mother alive	Mother dead	Both alive	Only father alive	Only mother alive	Both dead	Missing information on father/ mother

Note: Table is based on de jure members, i.e., usual residents.
[1] Includes children with father dead, mother dead, both dead and one parent dead but missing information on survival status of the other parent.

Table 2.12 presents the percentage of children age 10-14 who are attending school, by the survivorship of their parents. The results show a high level of school attendance overall among both boys and girls, regardless of whether or not a parent is deceased (96 percent and 98 percent respectively). It is sometimes assumed that becoming an orphan jeopardises a child's chances of attending school, but the data in Table 2.12 do not strongly support this conjecture. In fact, the greatest differential is seen in the lowest wealth quintile, in which only 89 percent of children living with at least one parent are attending school, as compared with 94 percent of double orphans (both parents have died).

Table 2.12 School attendance by survivorship of parents

For de jure children 10-14 years of age, the percentage attending school by parental survival and the ratio of the percentages attending school, by parental survival, according to background characteristics, Kenya 2014

[1] Ratio of the percentage with both parents deceased to the percentage with both parents alive and living with at least one parent

2.9 EDUCATION OF THE HOUSEHOLD POPULATION

Education is a key determinant of the lifestyle and status an individual enjoys in a society. Studies have consistently shown that educational attainment has a strong effect on health behaviours and attitudes. Results from the 2014 KDHS can be used to look at educational attainment among household members and school attendance ratios among youth.

2.9.1 Educational Attainment

Tables 2.13.1 and 2.13.2 present data on the educational attainment of household members age 6 and older. Continuing a trend found in earlier KDHS surveys, the data show a slight decrease in the proportion of women and men with no education. Compared with the 2008-09 KDHS, the 2014 KDHS shows a decline from 19 percent to 16 percent among women and from 13 percent to 11 percent among men. As expected, more men (13 percent and 8 percent, respectively) than women (10 percent and 7 percent, respectively) have completed a secondary education and more than a secondary education.

Table 2.13.1 Educational attainment of the female household population

Percent distribution of the de facto female household population age six and over by highest level of schooling attended or completed and median years completed, according to background characteristics, Kenya 2014

Total	15.9	42.5	15.6	9.6	9.6	6.7	100.0	58,608	5.8

Note: Totals may not add up to 100 percent because individuals with missing information on education are not shown separately. Total includes seven women for whom information on age is missing.
[1] Completed Grade 8 at the primary level, for those under age 45; because of the change in the school system in the 1980s, those age 45 and above are considered to have completed primary if they completed grade 7
[2] Completed Form 4 at the secondary level

With the exception of children age 6-9, fewer males than females have never been to school. In that age group, boys (38 percent) are more likely than girls (34 percent) to have never attended school. Meanwhile, 4 percent of both boys and girls age 10-14 have never been to school, indicating that boys enrol in school slightly later than girls. However, the proportion of the population with no education steadily increases thereafter with age, as does the gap between the proportion of males and females with no education, indicating a gender differential in educational attainment as students age.

Nationally, the median number of years of schooling completed is slightly higher among males (6.3 years) than females (5.8 years). Over the years, median number of years of schooling completed has been increasing among both men (from 5.0 in 2003 and 6.0 in 2008-09 to 6.3 in 2014) and women (from 4.3 in 2003 and 5.2 in 2008-09 to 5.8 in 2014).

About twice as many women and men in rural areas as in urban areas have no education. The proportion of respondents who have never been to school varies rather dramatically across regions. For example, the proportion of women who have never been to school varies from a low of 5 percent in Nairobi to a high of 69 percent in North Eastern. As expected, the proportion of women and men with no education decreases dramatically as wealth increases.

Table 2.13.2 Educational attainment of the male household population

Percent distribution of the de facto male household population age six and over by highest level of schooling attended or completed and median years completed, according to background characteristics, Kenya 2014

[2] Completed Form 4 at the secondary level

2.9.2 School Attendance Ratios

Table 2.14 presents the primary school and secondary school net and gross attendance ratios (NAR and GAR) by household residence, region, and wealth quintile. The NAR for primary school is the percentage of the primary-school-age population (age 6-13) that is attending primary school. The NAR for secondary school is the percentage of the secondary-school-age population (age 14-17) that is attending secondary school. By definition, the NAR cannot exceed 100 percent. The GAR for primary school is the total number of primary school students of any age, expressed as a percentage of the official primary-school-age population. The GAR for secondary school is the total number of secondary school students of any age, expressed as a percentage of the official secondary-school-age population. If there are significant numbers of over-age and under-age students at a given level of schooling, the GAR can exceed 100 percent. Youth are considered to be attending school currently if they attended a formal academic school at any point during the given school year. Note that the NAR and GAR values reported here are not comparable with those from previous DHS surveys due to an improvement in the precision of calculation.

The NAR is 86 percent at the primary school level. It is slightly higher for girls (87 percent) than for boys (85 percent). Note, however, that differentials in attendance ratios are much greater across regions than between girls and boys. Sixty percent of boys age 6-13 in the North Eastern region are attending primary school, while 94 percent are attending in the Central region. Similarly, only 51 percent of girls age 6-13 in North Eastern are attending primary school, as compared with 95 percent of girls in Central. Large regional differentials also exist in secondary school attendance rates. As might be expected, the NAR for primary school is higher in urban (89 percent) than in rural (85 percent) areas, and it increases with increasing wealth.

Table 2.14 School attendance ratios

Net attendance ratios (NAR) and gross attendance ratios (GAR) for the de facto household population by sex and level of schooling; and the Gender Parity Index (GPI), according to background characteristics, Kenya 2014

[1] The NAR for primary school is the percentage of the primary-school age (6-13 years) population that is attending primary school. The NAR for secondary school is the percentage of the secondary-school age (14-17 years) population that is attending secondary school. By definition the NAR cannot exceed 100 percent.
[2] The GAR for primary school is the total number of primary school students, expressed as a percentage of the official primary-school-age population. The GAR for secondary school is the total number of secondary school students, expressed as a percentage of the official secondary-school-age population. If there are significant numbers of overage and underage students at a given level of schooling, the GAR can exceed 100 percent.
[3] The Gender Parity Index for primary school is the ratio of the primary school NAR(GAR) for females to the NAR(GAR) for males. The Gender Parity Index for secondary school is the ratio of the secondary school NAR(GAR) for females to the NAR(GAR) for males.

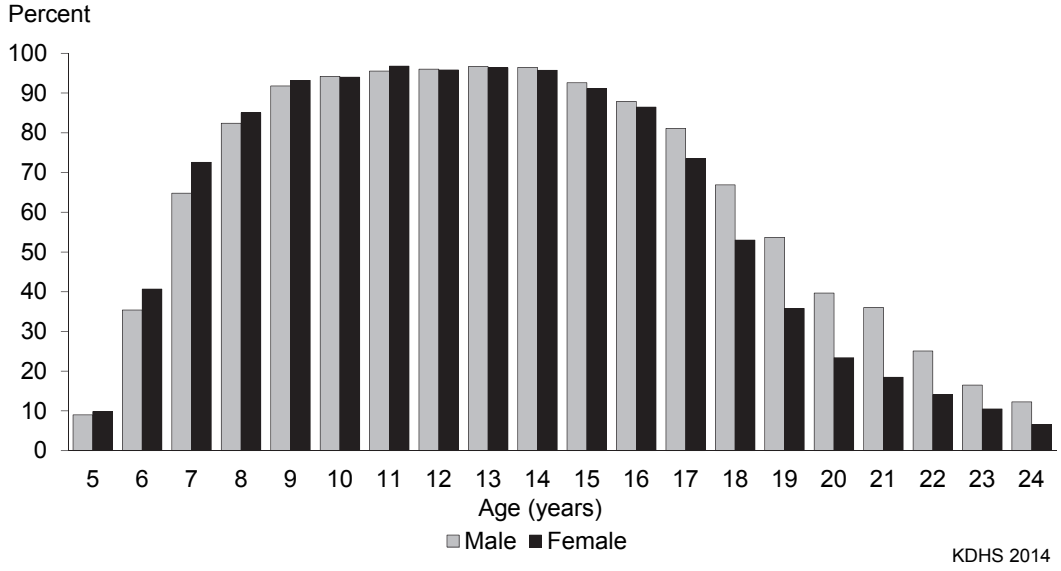
With the exception of North Eastern, GARs are quite high in all regions, indicating that a substantial number of boys and girls who are not of official primary school age are attending primary school.

Table 2.14 also shows the gender parity index (GPI), which assesses sex-related differences in school attendance rates. The GPI is calculated by dividing the GAR for the female population by the GAR for the male population. A GPI of less than 1 indicates a gender disparity in favour of the male population; that is, a higher proportion of males than females attend that level of schooling. A GPI greater than 1 indicates a gender disparity in favour of females. A GPI of 1 indicates parity or equality between the rates of participation for the sexes.

The GPI for NAR shows close to gender parity at the national level in both primary and secondary school; however, the GPI for GAR at the primary (0.97) as well as the secondary (0.95) level is skewed to favour male children. Differentials across the country exist, especially at the secondary school level. Among the regions, North Eastern has the lowest NARs, GARs, and GPIs for both primary and secondary school.

Figure 2.2 illustrates age-specific attendance rates, that is, the percentage of a given age cohort attending school regardless of the level attended (primary, secondary, or higher). At age 5-10, attendance rates are higher among girls than they are among boys. Between age 10 and age 14, the peak ages of school attendance, boys and girls attend in similar proportions. At age 15 and older, attendance rates decline among both boys and girls, and the gender differential in favour of boys increases with increasing age.

Figure 2.2 **Age-specific school attendance rates of the de-facto population age 5 to 24 years**



CHARACTERISTICS OF RESPONDENTS 3

Michael M. Musyoka, John K. Bore, Godfrey Odhiambo Otieno

Key Findings

- The percentage of women and men with no education has dropped by half over the last 10 years, from 13 percent and 6 percent in 2003 to 7 percent and 3 percent, respectively, in the 2014 KDHS. Over the same period, the percentage of women and men with at least some secondary education increased from 29 percent and 37 percent in 2003 to 43 percent and 49 percent, respectively, in 2014.
- Eighty-eight percent of women and 92 percent of men are literate.
- Twenty-three percent of women and 10 percent of men are not exposed to any source of mass media.
- Sixty-one percent of women and 80 percent of men are currently employed. Women are mostly employed in agricultural or domestic service positions, while men are mostly employed in agricultural, unskilled manual, or domestic service positions.

This chapter provides a description of the respondents who were interviewed in the 2014 KDHS. Women age 15-49 and men age 15-54 were interviewed in the course of the survey. This information is useful for understanding the context of the reproductive and health status of women and men discussed in later chapters of this report. Percent distributions of various demographic and socioeconomic characteristics are shown for the full sample. Data are provided on the main background characteristics discussed in subsequent chapters, including age at the time of the survey, marital status, urban/rural residence, region, educational level, and the wealth quintile to which respondents belong. In addition, information is provided on employment and work status.

3.1 CHARACTERISTICS OF SURVEY RESPONDENTS

Table 3.1 presents the percent distribution of women and men age 15-49 by the following background characteristics: age, religion, ethnic group, marital status, residence, region, education, and wealth quintile.

The distribution of both women and men tends to decline with increasing age, reflecting the comparatively young age structure of the Kenyan population. Thirty-seven percent of women and 39 percent of men are in the 15-24 age group. Thirty-four percent of women and 32 percent of men are in the 25-34 age group. The remaining respondents (29 percent of both women and men) are age 35-49.

The majority of both women (71 percent) and men (68 percent) are Protestant or another Christian denomination. Twenty percent of women and 21 percent of men are Roman Catholic, 7 percent of both women and men are Muslim, and 2 percent of women and 4 percent of men have no religion.

Ethnic affiliation is associated with various demographic behaviours because of differences in cultural beliefs. For example, in Kenya, certain ethnic groups encourage initiation to some rites while others consider them as taboo. The largest ethnic groups are the Kikuyu (women, 22 percent; men, 21 percent) and Luhya (women, 15 percent; men, 16 percent). Eleven to 12 percent of women and 11 to 13 percent of men are Luo, Kamba, or Kalenjin. Six percent or less of both women and men belong to other ethnic groups.

Sixty percent of women and 51 percent of men are married or living in an informal union. About 4 in 10 men (44 percent) have never been married, as compared with about 3 in 10 (29 percent) women. Women (11 percent) are more likely than men (5 percent) to be divorced, separated, or widowed.

Fifty-nine percent of women and 56 percent of men live in rural areas. The Rift Valley region has a quarter of all women (26 percent) and men (25 percent). The North Eastern region has 2 percent of all

women and men. The remaining regions each have between 10 percent and 15 percent of the remaining population.

Slightly more women (7 percent) than men (3 percent) have no education. Twenty-six percent of both women and men did not finish primary school. Slightly more women (25 percent) than men (23 percent) ended their schooling by completing primary school, and thereafter slightly fewer women than men obtained some secondary education, completed secondary education, or advanced beyond secondary education. The smallest proportions of both women (16 percent) and men (14 percent) are in the lowest wealth quintile. Almost half of the population (48 percent of women and 49 percent of men) is in the two highest wealth quintiles.

The distribution of female and male respondents by county shows that more respondents live in Nairobi, Kiambu, and Nakuru (between 5 percent and 13 percent) than the other 44 counties (Table 3.1C).

3.2 EDUCATIONAL ATTAINMENT BY BACKGROUND CHARACTERISTICS

Tables 3.2.1 and 3.2.2 show the percent distribution of women and men age 15-49 by educational attainment and median years of schooling completed, according to background characteristics. Men have achieved more education than women. In 2014, the proportion of women with no education declined marginally to 7 percent from the 9 percent figure recorded in the 2008-09 KDHS, but this proportion remains more than twice that of men with no education (3 percent).

Table 3.2.1 shows that 93 percent of women age 15-49 have attended school. Five in 10 women either have some primary education (26 percent) or have completed primary education (25 percent). Three in 10 have either some secondary education or a completed secondary education (16 percent each). One in 10 (11 percent) have gone beyond a secondary education, an increase from 7 percent in 2008-09.

The urban-rural difference in level of education is pronounced for women on either end of the educational attainment scale. Four percent of urban women have no education compared with 9 percent of rural women, and 14 percent of urban women have some primary education compared with 34 percent of rural women. About a quarter of women in both rural and urban areas have completed primary education, and 16 percent of women in both areas have some secondary education. The differences pick up again for women who have completed secondary school (urban women, 23 percent; rural women, 11 percent) or gone beyond secondary school (urban women, 19 percent; rural women, 6 percent). At the regional level, Nairobi had the highest proportion of women with more than a secondary education (24 percent), although this figure was a decline from the 31 percent reported in 2008-09. The North Eastern region had the most women with no education at 75 percent, a slight improvement from 78 percent in 2008-09.

Education increases with wealth; 31 percent of women in the lowest wealth quintile have no education, as compared with 2 percent of women in the highest wealth quintile. Almost one in three (29 percent) women in the highest quintile have more than a secondary education, compared with only one in 10 (10 percent) women in the fourth highest wealth quintile. Table 3.2.2 shows similar patterns in educational attainment among men, although men are more educated than women. County level differences are presented in Table 3.2.1C and Table 3.2.2C.

Table 3.2.1 Educational attainment: Women

Percent distribution of women age 15-49 by highest level of schooling attended or completed, and median years completed, according to background characteristics, Kenya 2014

[2] Completed Form 4 at the secondary level

3.3 LITERACY

The ability to read and write empowers women and men. Literacy statistics are important for policymakers to determine how best to reach the populations they serve. In the 2014 KDHS, literacy was determined by respondents' ability to read all or part of a simple sentence. During data collection, interviewers carried a set of cards on which simple sentences were printed in 17 of the country's major languages (English, Swahili, Borana, Embu, Kalenjin, Kamba, Kikuyu, Kisii, Luhya, Maragoli, Luo, Maasai, Meru, Mijikenda, Pokot, Somali, and Turkana) for testing a respondent's reading ability. Those who had never been to school and those who had only a primary education were asked to read the cards in the language they were most familiar with. Those with a secondary education or higher were assumed to be literate.

Table 3.3.1 shows the percent distribution of women age 15-49 by level of schooling attended and level of literacy, along with the percentage literate, according to background characteristics. The proportion of literate women (88 percent) was slightly higher than in 2008-09 (85 percent). Eight percent of women could read part of a sentence.

Literacy declines with age and varies by place of residence. Ninety-four percent of women residing in urban areas are literate, as compared with 84 percent of rural women. Regional differences are notable, with the proportion of literate women being highest in Nairobi (97 percent) and lowest in North Eastern (24 percent). Literacy increases with wealth; virtually all women (97 percent) in the highest quintile are literate, compared with 58 percent of women in the lowest quintile.

Literacy among women age 15-49 at the county level was highest in Nandi and Nyamira (98 percent each). The counties with the lowest proportion of literate women were Wajir (21 percent), Mandera (24 percent), Turkana (25 percent), Garissa (26 percent), and Marsabit (36 percent). In most counties, the proportion of literate women is above 80 percent (Table 3.3.1C).

Men are more likely to be literate than women. Table 3.3.2 shows that 92 percent of men age 15-49 are literate, not much of a difference from the 91 percent figure reported in the 2008-09 KDHS. The pattern of literacy among men is similar to that of women. However, there are marked differences between men and women across age groups. Ninety-one percent of men age 45-49 are literate, as compared with 78 percent of women in the same age group. The absolute difference in urban-rural literacy among men (8 percentage points) is slightly lower than that among women (10 percentage points). Men in the North Eastern region are more likely to be illiterate (32 percent) than those in the other regions. County level differences for men are presented in Table 3.3.2C and are similar to those observed among women.

Table 3.3.1 Literacy: Women

Percent distribution of women age 15-49 by level of schooling attended and level of literacy, and percentage literate, according to background characteristics, Kenya 2014

Background characteristic	Secondary school or higher	No schooling or primary school: Can read a whole sentence	No schooling or primary school: Can read part of a sentence	No schooling or primary school: Cannot read at all	No schooling or primary school: No card with required language	No schooling or primary school: Blind/ visually impaired	Total	Percentage literate[1]	Number of women

Note: Totals may not add up to 100 percent because men with missing information are not shown separately.
[1] Refers to men who attended secondary school or higher and men who can read a whole sentence or part of a sentence

3.4 ACCESS TO MASS MEDIA

Information access is essential in increasing people's knowledge and awareness of the world around them, which may eventually influence their perceptions and behaviour. Exposure to media was assessed by asking respondents how often they read a newspaper, watched television, or listened to a radio. It is important to know the types of persons who are more or less likely to be reached by the various types of media to plan programmes intended to spread information about health and family planning. Tables 3.4.1 and 3.4.2 show the percentage of women and men age 15-49 exposed to different types of mass communication media by background characteristics. Tables 3.4.1C and 3.4.2C show these data by county.

Women are less likely than men to have access to mass media; this is true for all types of media. Radio is the most popular medium for both women and men (accessed at least weekly by 70 percent of women and 86 percent of men), while newspapers are the least popular medium (accessed at least weekly by 18 percent of women and 41 percent of men). Only 11 percent of women and 33 percent of men have weekly exposure to all three media sources. Twenty-three percent of women and 10 percent of men have no weekly access to mass media.

There are no overarching patterns in media consumption by age group, although newspaper reading declines among women with age (as does literacy, noted above) and men age 15-19 are much less likely to have weekly exposure to any of the media than men in other age groups.

Urban women and men have more access to all forms of mass media than their rural counterparts; only 13 percent of women and 28 percent of men in rural areas read a newspaper at least once a week, as compared with 25 percent of women and 58 percent of men in urban areas. Although 66 percent of women and 78 percent of men in urban areas watch television at least once a week, only 20 percent of women and 44 percent of men residing in rural areas do so. Access to all three forms of mass media is highest among women in the Central region (18 percent) and men in Central and Nairobi (52 percent each) and lowest among residents of the North Eastern region (2 percent for women and 4 percent for men).

Access to mass media increases with increasing education and wealth among both women and men. The proportion of women who listen to the radio at least once a week increases from 28 percent among those with no education to 79 percent among those with at least some secondary schooling. Similarly, the proportion of women who watch television at least once a week increases from only 3 percent among those in the lowest wealth quintile to 90 percent among those in the highest quintile.

Across counties, women in Kiambu (27 percent), Nakuru and Nyeri (21 percent each) are most likely to have access to all three media at least once a week. Counties where the highest proportions of women have no access to any of the three media sources at least once a week are Turkana (80 percent), Garissa (77 percent), and Wajir (72 percent).

Men in Mombasa and Nyeri (71 percent each) and in Machakos and Kajiado (62 percent each) have higher access to all three media services at least once a week than their counterparts in the other counties. The counties with the highest proportions of men with no access to the three media services at least once a week are Turkana (84 percent), Wajir (51 percent), and Garissa (48 percent).

Table 3.4.1 Exposure to mass media: Women

Percentage of women age 15-49 who are exposed to specific media on a weekly basis, by background characteristics, Kenya 2014

Background characteristic	Reads a newspaper at least once a week	Watches television at least once a week	Listens to the radio at least once a week	Accesses all three media at least once a week	Accesses none of the three media at least once a week	Number of women

3.5 EMPLOYMENT

3.5.1 Employment Status

The 2014 KDHS asked respondents a number of questions regarding their employment status, including whether they were working in the seven days preceding the survey and, if not, whether they had worked in the 12 months before the survey. The results for women and men are presented in Tables 3.5.1 and 3.5.2.

At the time of the survey, 61 percent of women were employed and 5 percent were not currently employed but had worked sometime during the past 12 months (Figure 3.1). In general, the proportion of women who are currently employed increases with age, peaking at age 40-44 (84 percent) before dropping slightly at age 45-49 (80 percent). Employment increases with the number of living children. The North Eastern region has the lowest proportion of women who are currently employed (13 percent). Women with no education are less likely to be currently employed (43 percent) than those with any degree of education (60 percent and above). Similarly, women in the lowest wealth quintile are less likely to be currently employed (50 percent) than women in the other quintiles (61 percent or higher).

Men are more likely to be currently employed (80 percent) than women. The 15-19 age group has the lowest employment (35 percent); thereafter, employment rises more sharply than for women. Urban men are more likely to be currently employed (84 percent) than rural men (77 percent). Patterns are similar to those found with women by region and wealth quintile, but men at the highest level of education are less likely to be employed than men with no education.

Since the 2008-09 KDHS, current employment has improved among women (from 57 percent to 61 percent) but has declined among men (from 86 percent to 80 percent).

Figure 3.1 **Women's employment status in the past 12 months**

[1] "Currently employed" is defined as having done work in the past seven days. Includes persons who did not work in the past seven days but who are regularly employed and were absent from work for leave, illness, vacation, or any other such reason.

3.5.2 Occupation

Respondents who were currently employed or had worked in the 12 months preceding the survey were asked to specify their occupation. Table 3.6.1 and Table 3.6.2 show the percent distribution of women and men age 15-49 by occupation according to background characteristics.

Most of the women (a combined 59 percent) in Kenya are employed in either agriculture or domestic service. The other notable occupations include professional, technical, or managerial (14 percent); sales and services (14 percent); and unskilled manual labour (10 percent). There is a great deal of variation by background characteristics.

Employed men age 15-49 are mostly engaged in agricultural, unskilled manual, or domestic service occupations (24 percent, 22 percent, and 21 percent, respectively). As among women, 14 percent of men work in professional, technical, or managerial occupations.

Table 3.6.1 Occupation: Women

Percent distribution of women age 15-49 employed in the 12 months preceding the survey by occupation, according to background characteristics, Kenya 2014

3.5.3 Earnings, Employers, and Continuity of Employment

Table 3.7 shows the percent distribution of women age 15-49 by type of earnings, type of employer, and continuity of employment, by whether their work is agricultural or nonagricultural.

Almost two in every three women (66 percent) are paid cash only for their work. This is mostly in nonagricultural work (83 percent, compared with 29 percent for agricultural work). Forty-three percent of those who work in agriculture are not paid, while 9 percent are paid in-kind.

Half of Kenyan women (52 percent) are self-employed. Most of those in agricultural work are self-employed (68 percent), while women doing nonagricultural work are slightly more likely to be employed by a nonfamily member (50 percent) than to be self-employed (45 percent).

Sixty-five percent of women are employed year-round, and 28 percent are employed on a seasonal basis. Nonagricultural work is more continuous than agricultural work, with 73 percent of women doing nonagricultural work employed all year compared with 49 percent of women doing agricultural work.

Table 3.7 Type of employment among women

Percent distribution of women age 15-49 employed in the 12 months preceding the survey by type of earnings, type of employer, and continuity of employment, according to type of employment (agricultural or nonagricultural), Kenya 2014

Employment characteristic	Agricultural work	Nonagricultural work	Total
Type of earnings			
Cash only	29.0	82.8	65.7
Cash and in-kind	19.7	10.2	13.1
In-kind only	8.8	1.2	3.6
Not paid	42.5	5.7	17.5
Total	100.0	100.0	100.0

Total	100.0	100.0	100.0
Number of women employed during the last 12 months	3,038	6,587	9,712

Note: Total includes women with missing information on type of employment who are not shown separately.

MARRIAGE AND SEXUAL ACTIVITY 4

Ben Obonyo Jarabi, Samwel Ogola, Henry Z. Osoro

Key Findings

- The median age at first marriage among women age 25-49 is 20.2 years; the median age at first marriage among men age 30-49 is 25.3 years. Median age at marriage has remained stable in the past 10 years for both women and men.
- Six percent of currently married men are in a polygynous union; 11 percent of currently married women have co-wives.
- The percentage of women married by age 15 appears to be declining; 9 percent of women age 45-49 were married by age 15, as compared with 2 percent among those age 15-19.
- Fifteen percent of women age 20-49 had first sexual intercourse by age 15, 50 percent by age 18, and 71 percent by age 20. Twenty-two percent of men age 20-49 had first sexual intercourse by age 15, 56 percent by age 18, and 76 percent by age 20.

This chapter discusses the principal factors, other than contraception, that affect a woman's risk of becoming pregnant. These factors include marriage and sexual activity. Marriage signals the onset of exposure to the risk of pregnancy for most women and is an important fertility indicator. In the context of the 2014 KDHS, the term *married* refers to legal or formal marriage, and the phrase *living together* designates an informal union in which a man and a woman live together, whether or not a formal civil or religious ceremony has occurred. In later tables that do not list living together as a separate category, these women and men are included in the *currently married* group. Respondents who are currently married, divorced, separated, or widowed are referred to as *ever married*. This chapter also includes information on more direct measures of the beginning of exposure to pregnancy and the level of exposure, for example, age at first sexual intercourse and frequency of recent sexual intercourse.

4.1 CURRENT MARITAL STATUS

Marriage is a primary indication of regular exposure of women to the risk of pregnancy and therefore is important in the understanding of fertility. Populations in which age at first marriage is low tend to have early childbearing and high fertility.

Table 4.1 shows the percent distribution of women and men by marital status, according to age. Sixty percent of women and 51 percent of men age 15-49 are currently in a union; the majority report being married, while 5 percent of women and 2 percent of men report living together as if married. A higher proportion of men (44 percent) than women (29 percent) have never been married. A lower proportion of men are divorced, separated, or widowed compared with women (5 percent and 11 percent, respectively).

Table 4.1 Current marital status

Eleven percent of women age 15-19 are currently married, as compared with just 1 percent of men age 15-19. The proportion of women who are married increases rapidly between age 15-19 and age 20-24 (from 11 percent to 48 percent); the highest proportion of women married are age 30-34 (73 percent). Among men, the percentage married increases most rapidly between age 20-24 and age 25-29 (from 15 percent to 54 percent). After age 35, 84 percent or more of men are married.

4.2 POLYGYNY

Polygyny, the practice of having more than one wife, has implications for the frequency of sexual activity and fertility. The extent of polygyny was measured in the 2014 KDHS by asking all currently married female respondents whether their husband or partner had other wives (co-wives) and, if so, how many. Currently married men were also asked whether they had one or more wives or partners with whom they were living.

Table 4.2.1 shows the percent distribution of currently married women by the number of co-wives they have, and Table 4.2.2 shows the percent distribution of currently married men by the number of wives they have, according to background characteristics. The results show that the majority of Kenyan women (86 percent) and men (95 percent) are in monogamous unions. Eleven percent of married women and 6 percent of married men are in polygynous unions. Three percent of women age 15-19 report that they have co-wives, and this proportion rises with age to 18-19 percent among women in the 40-44 and 45-49 age groups. The percentage of men having more than one wife rises from 1 percent among men age 20-24 to 11 percent among men age 45-49. Seven percent of urban women and 4 percent of urban men are in polygynous unions, as compared with 14 percent of rural women and 6 percent of rural men.

Women in the North Eastern region are most likely to be in polygamous unions (32 percent), followed by those in Nyanza (19 percent). Six percent or less of women in Nairobi and the Eastern and Central regions are in polygamous unions. Eighteen percent of men in the North Eastern region report being in a polygynous union, followed by 12 percent in Nyanza and 8 percent in Coast. Education is negatively associated with polygyny for both women and men, with the proportion of women in a polygynous union decreasing from 32 percent among those with no education to 6 percent among those with at least some secondary education and, similarly, from 16 percent to 4 percent among men. Among both women and men, wealth quintile is also negatively associated with polygyny. The proportion of women in a polygynous union ranges from 5 percent among those in the highest wealth quintile to 24 percent among those in the lowest wealth quintile, and for men, from 4 percent to 11 percent.

4.3 AGE AT FIRST MARRIAGE

The start of marriage is an important social and demographic indicator and, in most societies, represents the point in a person's life when childbearing first becomes acceptable. The duration of exposure to the risk of pregnancy depends primarily on the age at which women first marry. Women who marry early, on average, are more likely to have their first child at a young age and give birth to more children overall, contributing to higher fertility. Age at first marriage is defined as the age at which the respondent began living with her or his first spouse/partner.

Table 4.3 shows the percentage of women and men age 15-49 who were first married by specific ages, according to current age. Marriage occurs relatively early in Kenya; among women age 25-49, 29 percent were married by age 18, and 48 percent were married by age 20. The median age at first marriage among women age 25-49 is 20.2 years.

The median age at first marriage does not vary much across the age cohorts from 25-29 to 45-49, hovering around age 20. However, the proportion of women married by age 15 increases with age from about 2 percent among those currently age 15-19 to 9 percent among those currently age 40-49. This is an indication of rising age at first marriage.

Men tend to marry later than women. The median age at first marriage among men age 30-49 is 25.3 years. Eleven percent of men age 25-49 were married by age 20, and less than half (48 percent) were married before age 25. The median age at first marriage for men is almost constant across the age cohorts, reflecting stability over time.

Note: The age at first marriage is defined as the age at which the respondent began living with her/his first spouse/partner.
na = Not applicable due to censoring
a = Omitted because less than 50 percent of the women or men began living with their spouse or partner for the first time before reaching the beginning of the age group

Table 4.4 shows the median age at first marriage among women age 25-49 and men age 30-54, according to background characteristics. Urban women marry two years later than rural women (21.5 years and 19.5 years, respectively). Women from Nairobi, the region with the highest median at 22.1 years, marry about three years later than women from the North Eastern, Nyanza, and Western regions. Median age at first marriage increases with increasing education. Women with at least some secondary education marry about five years later than those with no education (22.7 years and 17.9 years, respectively). Also, women from the highest wealth quintile marry more than four years later than those from the lowest quintile.

Although some variation exists in the median age at first marriage for men, the range in age at marriage is not as broad by background characteristics as it is for women. Urban men marry one year later than rural men. Men from the Nairobi, Coast, and Central regions have the highest median age at first marriage (26.0 years or greater), while those from the Nyanza and Western regions have the lowest median age (23.8 and 24.1 years, respectively). Wealth quintile has a positive association with men's age at first marriage, as it does for women, but the age range is only 2 years for men, whereas it is 5 years for women.

Table 4.4 Median age at first marriage by background characteristics

Median age at first marriage among women age 25-49, and median age at first marriage among men age 30-54, according to background characteristics, Kenya 2014

4.4 AGE AT FIRST SEXUAL INTERCOURSE

Age at first marriage is often used as a proxy for first exposure to sexual intercourse, but the two events do not necessarily occur at the same time. In the 2014 KDHS, women and men were asked how old they were when they first had sexual intercourse. Table 4.5 shows the percentage of women and men who had first sexual intercourse by specific ages and the median age at first intercourse, irrespective of marital status. This information allows an assessment of the age at which women and men start having sexual intercourse and the trends across age cohorts.

Fifteen percent of women age 20-49 had first sexual intercourse by age 15, 50 percent by age 18, and 71 percent by age 20. Older women are slightly more likely to have had their first sexual encounter at an earlier age. Men have an earlier sexual debut than women, a pattern that holds true for most age groups. For example, 22 percent of men age 20-49 had first sexual intercourse by age 15, 56 percent by age 18, and 76 percent by age 20. The median age at first sexual intercourse among men age 20-49 (17.4 years) is also slightly lower than that among women (18.0 years).

Three percent of both women and men age 20-49 have never had sexual intercourse, while 37 percent of women and 38 percent of men age 15-24 have never had sexual intercourse. There does not appear to be a change in age at first sex compared with the 2008-09 KDHS.

Table 4.5 Age at first sexual intercourse

Percentage of women and men age 15-49 who had first sexual intercourse by specific exact ages, percentage who never had sexual intercourse, and median age at first sexual intercourse, according to current age, Kenya 2014

na = Not applicable due to censoring
a = Omitted because less than 50 percent of the respondents had sexual intercourse for the first time before reaching the beginning of the age group

Table 4.6 shows the median age at first sexual intercourse among women age 20-49 and 25-49 and men age 20-54 and 25-54 by background characteristics. Women in rural areas initiate sexual activity slightly earlier than their urban counterparts. Among women age 20-49, sexual activity begins earliest in the Nyanza region (16.4 years) and latest in Nairobi (19.3 years). With respect to education, women with at least some secondary education begin sexual activity three years later than those with no education. Similarly, women in the highest wealth quintile tend to initiate sexual activity three years later than those in the lowest.

The data for men age 25-54 show fewer and less dramatic patterns than those seen among women. There are minimal differences in median age by residence, education, and wealth. By region, however, differences in median age at first sex are more substantial. The median age at first sex for men in the Eastern region is 16.1 years, as compared with 24.1 years for men in the North Eastern region.

Table 4.6 Median age at first sexual intercourse by background characteristics

Median age at first sexual intercourse among women age 20-49 and age 25-49, and median age at first sexual intercourse among men age 20-54 and age 25-54, according to background characteristics, Kenya 2014

a = Omitted because less than 50 percent of the respondents had intercourse for the first time before reaching the beginning of the age group

At the county level, the five counties with the highest median age at first sexual intercourse for women are Mandera (19.4 years), Tharaka-Nithi (19.4), Kiambu (19.4), Mombasa (19.3), and Nairobi (19.3). The counties with the lowest median age include Migori (15.5), Homa Bay (15.7), Samburu (15.7), Kisumu (16.4), and Siaya (16.6). For men, Garissa (23.6) and Wajir (22.7) counties recorded the highest median age at first sexual intercourse, while Meru (14.4) and Samburu (15.0) had the lowest median age at first sexual intercourse (Table 4.6C).

4.5 RECENT SEXUAL ACTIVITY

In the absence of contraception, the probability of pregnancy is related to the regularity of sexual intercourse. Thus, information on sexual activity can give added perspective to measurement of exposure to pregnancy. The 2014 KDHS asked all women and men how long ago their last sexual intercourse occurred. Tables 4.7.1 and 4.7.2 show the percent distribution of women and men age 15-49 by the timing of their last sexual intercourse, according to background characteristics.

Fourteen percent of women and 15 percent of men age 15-49 have never had sexual intercourse. Twelve percent of women and 10 percent of men report that their last sexual encounter occurred more than one year before the survey. Slightly more than half of women (51 percent) and men (54 percent) reported that they had a recent sexual encounter (within the last four weeks). The proportion of both women and men who reported having a recent sexual encounter is similar to that observed in the 2008-09 KDHS.

The proportion of women who were sexually active within the last four weeks is lowest among those in the youngest age group of 15-19 (11 percent) and highest among those age 30-34 (69 percent). Similarly, the proportion of men sexually active in the last four weeks ranges from 10 percent among those age 15-19 to 80 percent among those age 40-44. By marital status, recent sexual activity is most common among those currently married or living together, with 80 percent of married women and 84 percent of married men having had sex in the four weeks before the survey. Male-female differences are greatest among those who have never been married and those who were formerly married. The proportion of never-married men who reported having a recent sexual encounter is about three times that of women (20 percent and 7 percent, respectively), and the proportion among formerly married men is more than twice that among women (37 percent and 17 percent, respectively). These patterns are similar to patterns in the 2003 and 2008-09 KDHS surveys.

Recent sexual activity for both women and men differed by rural-urban residence, with women and men in urban areas somewhat more likely than those in rural areas to report being sexually active in the four weeks preceding the survey. By region, women in Nairobi and Central are most likely to have been sexually active in the four weeks before the survey (55 percent), although regional differences are minimal. Regional variations are wider for men, with Nairobi having the highest proportion of men with recent sexual activity (61 percent) and North Eastern having the lowest (37 percent). There are no patterns evident in recent sexual activity by educational level or wealth among women and no evident pattern for education among men. The proportion of men with recent sexual activity is higher among those in the highest wealth quintile (61 percent) than among those in the other quintiles (50-53 percent).

Table 4.7.1 Recent sexual activity: Women

FERTILITY 5

Andrew Kyalo Mutuku, Samwel Ogola, Michael Musyoka

Key Findings

- The total fertility rate for the three years preceding the survey is 3.9 births per woman, with rural women having at least one child more than urban women.
- Fertility has decreased from 4.9 births per woman in 2003 to 3.9 births per woman in 2014, a one-child decline in the past 10 years.
- Half of births occur within three years of a previous birth, with 18 percent occurring within 24 months.
- Childbearing begins early in Kenya, with almost one-quarter of women giving birth by age 18 and nearly half by age 20.
- Eighteen percent of adolescent women age 15-19 are already mothers or pregnant with their first child. In the last five years, teenage pregnancy has remained unchanged.

One of the major objectives of the 2014 KDHS was to examine fertility levels, trends, and differentials in Kenya. Fertility is a principal component of population change that contributes to the size, structure, and composition of the population in a country. This chapter focuses on a number of fertility indicators including levels, patterns, and trends in both current and cumulative fertility; the length of birth intervals; and the age at which women begin childbearing. Birth intervals are important because short intervals are associated with high childhood mortality. The age at which childbearing begins can have a major impact on the health and well-being of both the mother and the child.

To generate data on fertility, a birth history was collected from each woman interviewed in the 2014 KDHS. Women were asked to report on the total number of sons and daughters to whom they had given birth in their lifetime. To ensure that all information was reported, women were asked separately about children still living at home, those living elsewhere, and those who had died. The sex, date of birth, and survival status of each child were obtained, and age at death for deceased children was recorded.

5.1 CURRENT FERTILITY

Measures of current fertility are presented in Table 5.1 for the three-year period preceding the survey, corresponding to the calendar period 2011-2014. A three-year period was used for calculating these rates to provide the most current information while also allowing the rates to be calculated for a sufficient number of cases so as not to compromise the statistical precision of the estimate. Age-specific fertility rates (ASFRs), expressed as the number of births per thousand women in a specified age group, show the age pattern of fertility.[1] The total fertility rate (TFR) is the number of live births a woman would have if she were subject to the current age-specific fertility rates throughout her reproductive period (age 15-49). More generalised indicators of fertility include the general fertility rate (GFR), expressed as the annual number of live births per 1,000 women age 15-44, and the crude birth rate (CBR), expressed as the annual number of live births per 1,000 population.

[1] Numerators for ASFRs are calculated by summing the live births that occurred in the three-year period preceding the survey classified according to the age of the mother (in five-year age groups) at the time of the child's birth. The denominators of the rates represent the number of woman-years lived by the survey respondents in each of the five-year age groups during the specified period.

Table 5.1 shows that the TFR is 3.9 births per woman. This means that a Kenyan woman would bear about four children in her lifetime if fertility were to remain constant at current levels. This represents a decrease since the 2008-09 KDHS, when the TFR was 4.6 births per woman. The TFR is higher among rural women than urban women (4.5 and 3.1, respectively), and this trend is evident across all age groups. The largest absolute difference is seen among women age 20-24; the ASFR for rural women of this age is 248 births per 1,000, compared with 164 per 1,000 among urban women. Rural-urban differences appear to be narrowing over time. In the 2008-09 KDHS, the TFR was 5.2 in rural areas and 2.9 in urban areas. The overall age pattern, as reflected in the ASFRs, indicates that fertility is low among adolescents, increases to a peak of 206 births per 1,000 among women age 20-24, and declines thereafter. The table also shows a GFR of 141 live births per 1,000 women and a CBR of 30.5 live births per 1,000 population. This is a decrease from the figures of 161 and 34.8, respectively, reported in the 2008-09 KDHS.

Table 5.1 Current fertility

Age-specific and total fertility rates, the general fertility rate, and the crude birth rate for the three years preceding the survey, by residence, Kenya 2014

	Residence		
Age group	Urban	Rural	Total
15-19	81	106	96
20-24	164	248	206
25-29	149	214	183
30-34	119	170	148
35-39	73	116	100
40-44	23	45	38
45-49	6	10	9
TFR (15-49)	3.1	4.5	3.9
GFR	118	158	141
CBR	31.0	30.3	30.5

Note: Age-specific fertility rates are per 1,000 women. Rates for age group 45-49 may be slightly biased due to truncation. Rates are for the period 1-36 months prior to interview.
TFR: Total fertility rate expressed per woman
GFR: General fertility rate expressed per 1,000 women age 15-44
CBR: Crude birth rate, expressed per 1,000 population

5.2 FERTILITY DIFFERENTIALS

This section examines the association between a woman's background characteristics and her fertility. Table 5.2 presents the TFR, the percentage of women age 15-49 who are currently pregnant, and the mean number of children ever born to women age 40-49 by background characteristics. Fertility is lowest in Nairobi and Central region (TFRs of 2.7 and 2.8, respectively) and highest in North Eastern (6.4).

Table 5.2 Fertility by background characteristics

Total fertility rate for the three years preceding the survey, percentage of women age 15-49 currently pregnant, and mean number of children ever born to women age 40-49 years, by background characteristics, Kenya 2014

Background characteristic	Total fertility rate	Percentage of women age 15-49 currently pregnant	Mean number of children ever born to women age 40-49
Residence			
Urban	3.1	6.0	3.9
Rural	4.5	6.4	5.6
Region			
Coast	4.3	6.6	5.5
North Eastern	6.4	12.0	7.1
Eastern	3.4	4.6	4.7
Central	2.8	4.8	3.7
Rift Valley	4.5	7.0	5.5
Western	4.7	6.7	6.1
Nyanza	4.3	5.9	5.8
Nairobi	2.7	6.8	3.1
Education			
No education	6.5	11.0	6.5
Primary incomplete	4.8	6.3	6.0
Primary complete	4.2	6.3	5.1
Secondary+	3.0	5.4	3.7
Wealth quintile			
Lowest	6.4	9.4	6.7
Second	4.7	6.5	5.9
Middle	3.8	5.7	5.5
Fourth	3.1	5.7	4.3
Highest	2.8	5.0	3.4
Total	3.9	6.3	5.0

Note: Total fertility rates are for the period 1-36 months prior to interview.

Fertility rates decrease as women's education and wealth increase. Table 5.2 shows that the TFR decreases from 6.5 among women with no education to 4.8 among women with some education and further to 3.0 among women with a secondary or higher education. Fertility is also closely associated with wealth, with women in the lowest quintile (6.4) having more children than those in the highest quintile (2.8).

Table 5.2 shows that 6 percent of women were pregnant at the time of the survey. This may be an underestimate as women in the early stages of pregnancy may be unaware or unsure that they are pregnant, and some may choose not to declare that they are pregnant. Differentials in pregnancy rates are generally consistent with the pattern of fertility depicted across the various subgroups. The proportion of women who are pregnant is highest in North Eastern region (12 percent) and lowest in Eastern and Central (5 percent each). The findings show that the proportion of women who are currently pregnant declines as the level of education increases, from 11 percent among those with no education to 5 percent among those with a secondary or higher education.

Comparison of the mean number of lifetime births to older women with the current TFR can provide some insight into changes in fertility over the previous two decades or so. For example, the 2014 KDHS data show that the mean number of children ever born to women age 40-49 is 5.0, a decline from the figure of 5.6 reported in the 2008-09 KDHS and approximately one child more than the current TFR (3.9). On average, rural women age 40-49 have given birth to 5.6 children, as compared with only 3.9 among their urban counterparts. Women age 40-49 in Nairobi have the lowest mean number of children ever born (3.1), while those in the North Eastern region have the highest (7.1). The largest absolute differences between completed fertility at age 40-49 and the level of current fertility occur in Nyanza and Western regions (1.5 and 1.4, respectively). The mean number of children born to women age 40-49 decreases as education and wealth quintile increase.

Table 5.2C shows indicators of fertility by county. The county with the lowest TFR is Kirinyaga (2.3), followed by Nyeri, Kiambu, and Nairobi (2.7 each). The counties with the highest TFR are Wajir (7.8), West Pokot (7.2), Turkana (6.9), and Samburu (6.3). Counties with higher TFRs tend to be in northern Kenya.

Table 5.2C Fertility

Total fertility rate for the three years preceding the survey, percentage of women age 15-49 currently pregnant, and mean number of children ever born to women age 40-49 years, by county, Kenya 2014

5.3 FERTILITY TRENDS

Fertility trends can be further investigated using retrospective data from the birth histories collected in the 2014 KDHS. Table 5.3.1 shows age-specific fertility rates for successive five-year periods preceding the 2014 KDHS. Because women age 50 or above were not interviewed in the survey, the rates for older age groups are successively truncated for periods more distant from the survey date. For example, rates cannot be calculated for women age 35-39 for the period 15-19 years before the survey because these women are currently over age 50 and therefore not eligible to be interviewed. Fertility rates are lower in every age group during the period 0-4 years before the survey than they are in periods more distant from the survey, suggesting a decline in fertility over time.

Table 5.3.1 Trends in age-specific fertility rates

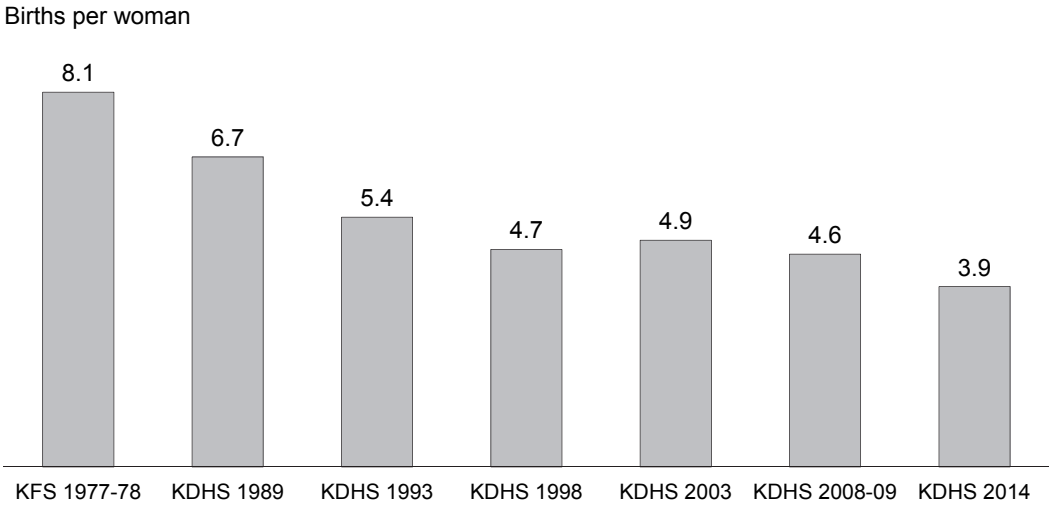
Age-specific fertility rates for five-year periods preceding the survey, by mother's age at the time of the birth, Kenya 2014

Mother's age at birth	Number of years preceding survey			
	0-4	5-9	10-14	15-19
15-19	101	120	132	120
20-24	206	228	247	253
25-29	193	216	238	243
30-34	154	192	198	[214]
35-39	106	127	[160]	
40-44	40	[76]		
45-49	[10]			

Note: Age-specific fertility rates are per 1,000 women. Estimates in brackets are truncated. Rates exclude the month of interview.

Kenya has undertaken many surveys that have collected data on fertility, allowing for examination of trends over the last few decades. Figure 5.1 and Table 5.3.2 compare age-specific and total fertility rates from estimates obtained since 1977. There was a sharp decline in the TFR between the 1977-78 Kenya Fertility Survey (8.1), the 1989 KDHS (6.7), and the 1993 KDHS (5.4), after which time there was further decline to 4.7 in the 1998 KDHS. Fertility seemed to rise, albeit marginally, afterwards, to a TFR of 4.9 children reported in 2003. The decrease in the TFR from 4.9 and 4.6 in the 2003 and 2008-09 KDHS surveys, respectively, to the current 3.9 indicates that Kenya's fertility is again on the decline. The TFR of 3.9 is the lowest ever recorded in Kenya.

Figure 5.1 **Trends in total fertility rate, 1978-2014***



* Data from 2003 and later are nationally representative while data before 2003 exclude North Eastern region and several northern districts in the Eastern and Rift Valley regions.

Table 5.3.2 Trends in age-specific and total fertility rates

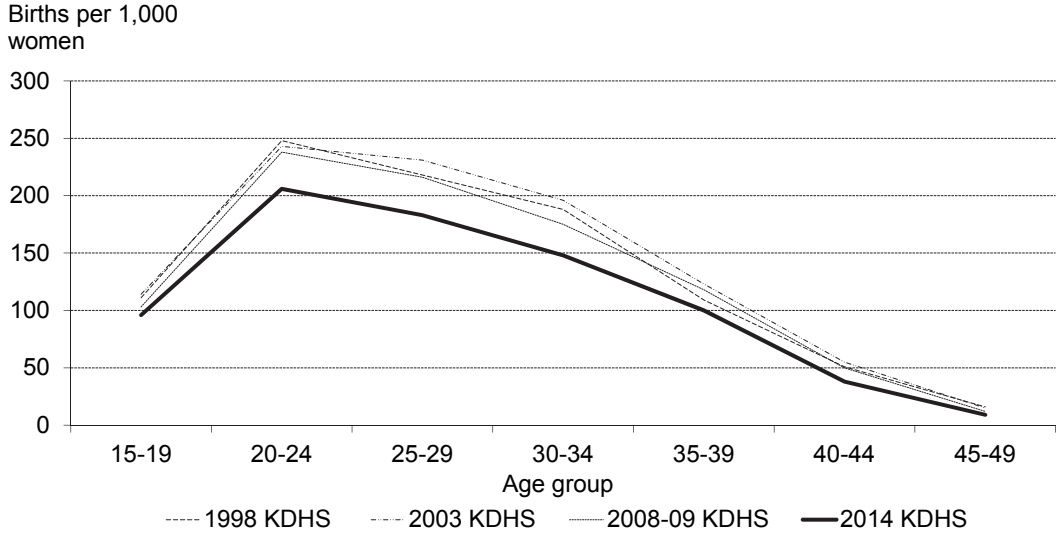
Age-specific and total fertility rates (TFR) for the three-year period preceding several surveys

Mother's age at birth	1977/78 KFS[1] 1975-78	1989 KDHS[1] 1984-88	1993 KDHS[1] 1990-92	1998 KDHS[1] 1995-97	1999 Census	2003 KDHS 2000-02	2008-09 KDHS 2006-08	2014 KDHS 2011-2013
15-19	168	152	110	111	142	114	103	96
20-24	342	314	257	248	254	243	238	206
25-29	357	303	241	218	236	231	216	183
30-34	293	255	197	188	185	196	175	148
35-39	239	183	154	109	127	123	118	100
40-44	145	99	70	51	56	55	50	38
45-49	59	35	50	16	7	15	12	9
TFR 15-49	8.1	6.7	5.4	4.7	5.0	4.9	4.6	3.9

Note: Age-specific fertility rates are per 1,000 women. Rates refer to the three-year period preceding the surveys except for the 1989 KDHS, which used a five-year period and the 1999 census, which used a period that varied with the age groups used to make the adjustment.
Sources: NCPD et al., 1999; Central Bureau of Statistics, 2002b.
[1] Data exclude North Eastern region and several northern districts in the Eastern and Rift Valley regions.

Table 5.3.2 and Figure 5.2 show the ASFRs for recent surveys. The largest decline in fertility is seen among women of peak childbearing ages (20-34).

Figure 5.2 **Trends in age-specific fertility rates**



Data collected before 2003 exclude North Eastern region and several northern districts in the Eastern and Rift Valley.

5.4 CHILDREN EVER BORN AND LIVING

Information on children ever born (or parity) is useful in looking at how average family size varies across age groups. The percentage of currently married women in their 40s who have never had children also provides an indicator of the inability to bear children in societies in which voluntary childlessness is rare. Comparisons of differences in the mean number of children ever born and surviving reflect the cumulative effects of mortality levels during the period in which women have been bearing children.

Table 5.4 shows the percent distribution of all women and currently married women by number of children ever born, mean number of children ever born, and mean number of children living. In Kenya, childbearing starts early and is nearly universal. Eighty-five percent of women age 15-19 have never given birth, as compared with only 35 percent of women age 20-24 and 12 percent of women age 25-29. In the subsequent age groups, the percentage of women who have never given birth drops to 4 percent or lower. A similar pattern is observed among currently married women. The proportion of women who have never given birth declines from 32 percent among those age 15-19 to 5 percent or less among those age 25 and above.

Table 5.4 Children ever born and living

Percent distribution of all women and currently married women age 15-49 by number of children ever born, mean number of children ever born and mean number of living children, according to age group, Kenya 2014

Parity increases with age. On average, a woman in Kenya has given birth to more than two children by her late 20s and to more than four children by her late 30s. These figures are slightly lower than those reported in the 2008-09 KDHS. In all age groups, the mean number of children ever born is higher among currently married women than among women overall. The largest difference is in the youngest age group (15-19). Currently married women age 15-19 have an average of 0.9 children, compared with 0.2 children among all women age 15-19.

Because voluntary childlessness is rare in Kenya, it might be assumed that most married women with no births are unable to physiologically bear children. The percentage of women who are childless at the end of the reproductive period is an indirect measure of primary infertility (the proportion of women who are unable to bear children at all). Table 5.4 shows that primary infertility is less than 2 percent. Primary infertility has changed little since 2003.

The last column in Table 5.4 shows the mean number of living children. The difference between the mean number of children ever born (2.5) and living (2.3) is an indicator of the level of mortality in the population.

5.5 BIRTH INTERVALS

The length of time between births affects the overall level of fertility and also affects the health of both the mother and the child. Examining birth intervals provides insights into birth patterns and maternal and child health. Studies have shown that children born fewer than 24 months after a previous sibling are at greater risk of having poor health and that such births threaten maternal health. Table 5.5 shows the percent distribution of non-first births in the five years before the survey by the number of months since the preceding birth and the median number of months since the preceding birth, according to background characteristics.

Eighteen percent of Kenyan children are born less than 24 months after a previous birth. The most common birth interval category is 24-35 months (32 percent), while the least common birth interval is 7-17 months (7 percent). The median birth interval is 36.3 months, a slight increase from 33.1 months in the 2008-09 KDHS. The median birth interval increases with the age of the mother, is longer for children whose preceding sibling is living (36.8 months) than for those whose preceding sibling is dead (26.9 months), decreases with birth order, and is longer for urban children (41.0 months) than for rural children (34.7 months). There are regional variations; Central region has the longest median birth interval (53.9 months) and North Eastern the shortest (27.7 months). Median birth intervals increase with increasing mother's education and wealth.

Table 5.5 Birth intervals

Percent distribution of non-first births in the five years preceding the survey by number of months since preceding birth, and median number of months since preceding birth, according to background characteristics, Kenya 2014

Note: First-order births are excluded. The interval for multiple births is the number of months since the preceding pregnancy that ended in a live birth.

By county (Table 5.5C), the median birth interval is longest in Kirinyaga (65.4 months), Nyeri, Kiambu, Tharaka-Nithi, and Meru (each over 50 months) and shortest in Garissa, Wajir, West Pokot, and Narok (all less than 30 months).

Note: First-order births are excluded. The interval for multiple births is the number of months since the preceding pregnancy that ended in a live birth.

5.6 POSTPARTUM AMENORRHOEA, ABSTINENCE, AND INSUSCEPTIBILITY

Postpartum amenorrhoea refers to the interval between childbirth and the return of menstruation. The length and intensity of breastfeeding influence the duration of amenorrhoea, which offers protection from conception. Postpartum abstinence refers to the period between childbirth and the time when a woman resumes sexual activity. Women are considered to be insusceptible to pregnancy if they are not exposed to the risk of conception, either because their menstrual period has not resumed since giving birth or because they are abstaining from intercourse after childbirth.

Table 5.6 shows that the median duration of amenorrhoea among women who gave birth in the three years preceding the survey is 6.2 months and the median duration of postpartum abstinence is 3.0 months. The two factors, postpartum amenorrhoea and abstinence, taken together indicate that the median duration of postpartum insusceptibility to pregnancy is 8.6 months. Almost all women are insusceptible to pregnancy (98 percent) within the first two months following childbirth. The contribution of abstinence is greatly reduced after the second month. At 8-9 months, 41 percent of women are still amenorrhoeic, but only 18 percent are still abstaining. At 26-27 months after birth, insusceptibility drops to 10 percent or less.

Table 5.6 Postpartum amenorrhoea, abstinence and insusceptibility

Percentage of births in the three years preceding the survey for which mothers are postpartum amenorrhoeic, abstaining, and insusceptible, by number of months since birth, and median and mean durations, Kenya 2014

Months since birth	Percentage of births for which the mother is:			Number of births

Mean	9.7	6.3	11.9	na

Note: Estimates are based on status at the time of the survey.
na = Not applicable
[1] Includes births for which mothers are either still amenorrhoeic or still abstaining (or both) following birth

Table 5.7 shows the median duration of postpartum amenorrhoea, abstinence, and insusceptibility by background characteristics. Older women (age 30 and above) have a slightly longer median period of insusceptibility, even though they have a lower median duration of abstaining, because of the longer duration of postpartum amenorrhoea. Women living in urban areas report a shorter median duration of amenorrhoea and, hence, have a shorter period of insusceptibility than rural women (5.1 months versus 10.8 months). The median duration of both amenorrhoea and insusceptibility declines as education increases. Women in the lowest wealth quintile have the longest durations of amenorrhoea and abstinence, and thus insusceptibility.

Table 5.7 Median duration of amenorrhoea, postpartum abstinence and postpartum insusceptibility

Median number of months of postpartum amenorrhoea, postpartum abstinence, and postpartum insusceptibility following births in the three years preceding the survey, by background characteristics, Kenya 2014

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed. Medians are based on the status at the time of the survey (current status).
[1] Includes births for which mothers are either still amenorrhoeic or still abstaining (or both) following birth

5.7 MENOPAUSE

Another factor influencing the risk of pregnancy is menopause. In the 2014 KDHS, women were considered menopausal if they were neither pregnant nor postpartum amenorrhoeic and had not had a menstrual period in the six months preceding the survey (Table 5.8). Prevalence of menopause increases with age, ranging from 5 percent among women age 30-34 to 45 percent among women age 48-49. The proportion of women age 30-49 who are menopausal (11 percent) has not changed from the 2008-09 KDHS.

Table 5.8 Menopause

Percentage of women age 30-49 who are menopausal, by age, Kenya 2014

Age	Percentage menopausal[1]	Number of women
30-34	4.7	2,162
35-39	6.1	1,780
40-41	9.2	632
42-43	8.9	426
44-45	20.8	520
46-47	24.4	424
48-49	45.1	343
Total	10.7	6,286

[1] Percentage of all women who are not pregnant and not postpartum amenorrhoeic whose last menstrual period occurred six or more months preceding the survey

5.8 AGE AT FIRST BIRTH

The age at which childbearing starts has important consequences for the overall level of fertility as well as the health and welfare of the mother and the child. Early age at initiation of childbearing lengthens the reproductive period. Table 5.9 shows the percentage of women age 15-49 who gave birth by exact ages, the percentage who have never given birth, and the median age at first birth, according to current age. Medians for women age 15-24 are not presented because less than 50 percent had given birth before age 15.

Table 5.9 Age at first birth

Percentage of women age 15-49 who gave birth by specific exact ages, percentage who have never given birth, and median age at first birth, according to current age, Kenya 2014

Current age	Percentage who gave birth by exact age					Percentage who have never given birth	Number of women	Median age at first birth
	15	18	20	22	25			
15-19	1.4	na	na	na	na	85.3	5,820	a
20-24	4.1	23.3	43.0	na	na	35.3	5,735	a
25-29	4.9	25.7	46.8	64.4	81.3	11.5	6,100	20.3
30-34	3.7	24.8	48.3	67.7	82.9	3.7	4,510	20.2
35-39	4.4	21.7	44.4	65.5	83.6	3.3	3,773	20.5
40-44	4.7	25.0	47.5	68.4	85.2	2.6	2,885	20.2
45-49	5.4	29.8	50.7	69.5	85.0	1.9	2,257	19.9
20-49	4.5	24.7	46.3	na	na	12.4	25,259	a
25-49	4.6	25.1	47.2	66.6	83.1	5.7	19,524	20.3

na = Not applicable due to censoring
a = Omitted because less than 50 percent of women had a birth before reaching the beginning of the age group

The median age at first birth for women age 25-29 is 20.3 years and is relatively unchanged from that reported in the 2008-09 KDHS (19.8). One-quarter of Kenyan women age 25-49 (25 percent) have given birth by age 18, while about half (47 percent) have given birth by age 20. The median age at first birth does not vary much across age groups, indicating no change over time in median age at first birth.

Table 5.10 presents the median age at first birth among women age 25-49 by background characteristics. In all age groups, women in urban areas have a slightly higher median age at first birth than their rural counterparts. The highest median age at first birth among women age 25-49 was recorded in Nairobi (22.2), while the lowest was observed in Nyanza (18.9). This implies that, on average, women in Nyanza have their first birth about three years earlier than those in Nairobi. Table 5.10C reflects these regional findings in that the counties of Homa Bay, Migori, and Siaya, all located in Nyanza, report some of the lowest median ages at first birth.

Table 5.10 Median age at first birth

Median age at first birth among women age 25-49 years, by background characteristics, Kenya 2014

Total	20.3	20.2	20.5	20.2	19.9	20.3

Age at first birth increases with increasing education; on average, women with at least some secondary education begin childbearing more than three years after women with no education (22.5 and 19.2, respectively). Similarly, women in the highest wealth quintile have their first birth about three and one-half years later, on average, than women in the lowest quintile.

5.9 TEENAGE PREGNANCY AND MOTHERHOOD

Teenage pregnancy and motherhood has remained a major health and social concern because of its association with higher morbidity and mortality for both the mother and the child. Childbearing during the teenage years also frequently has other adverse social consequences, particularly for female educational attainment, as women who become mothers in their teens are more likely to curtail education.

Table 5.11 presents the percentage of women age 15-19 who have had a live birth or who are pregnant with their first child and the percentage of women who have begun childbearing by selected background characteristics. Fifteen percent of women age 15-19 have already had a birth, and 3 percent are pregnant with their first child. The percentage of women who have begun childbearing increases rapidly with age, from about 3 percent among those age 15 to 40 percent among those age 19.

Table 5.11 Teenage pregnancy and motherhood

Highest	8.1	2.1	10.2	1,116
Total	14.7	3.4	18.1	5,820

While rural-urban differences are small, the prevalence of early childbearing varies by region, ranging from 10 percent in Central region to 21 percent in Rift Valley and Coast and 22 percent in Nyanza. One-third of women age 15-19 with no education (33 percent) have begun childbearing, as compared with only 12 percent among those who have a secondary or higher education (Table 5.11). Similarly, teenagers from the poorest households are more likely to have begun childbearing (26 percent) than teenagers from the wealthiest households (10 percent). The proportion of teenagers who have begun childbearing has not changed since the 2008-09 KDHS.

At the county level (Table 5.11C), early childbearing is lowest in Murang'a, Nyeri, Embu, and Elgeyo Marakwet (less than 10 percent each) and highest in Samburu, Nyamira, Tana River, West Pokot, Homa Bay, and Narok (more than 25 percent each).

FERTILITY PREFERENCES 6

Samwel Ogola, Michael Musyoka, Andrew Kyalo Mutuku

Key Findings

- Half of currently married women age 15-49 and 42 percent of currently married men age 15-49 want no more children or are sterilised.
- The mean ideal number of children among all women age 15-49 is 3.6, while that of all men is 3.9. The mean ideal number of children among women has declined marginally in the last 10 years from 3.9 in the 2003 KDHS to 3.6 in 2014.
- The gap between actual fertility and ideal family size has narrowed in the last 10 years, from 1.3 children in 2003 to 1.0 in 2014.

Information on fertility preferences is of considerable importance to family planning programmes because it allows planners to assess the need for contraception, whether for spacing or limiting of births, and also to assess the extent of unwanted and mistimed pregnancies. Data on fertility preferences may also be useful as an indicator of the direction that future fertility efforts of a country's citizens may take.

The 2014 KDHS included questions to ascertain fertility preferences. Women who were either not pregnant or unsure about their pregnancy status were asked the following question: *Would you like to have (a/another) child or would you prefer not to have any (more) children?* A different question was posed to women who were pregnant at the time of the survey. Pregnant women were asked *After the child you are expecting now, would you like to have another child or would you prefer not to have any more children?* Women who indicated that they wanted another child were asked how long they would like to wait before the birth of the next child. Finally, women were asked the total number of children they would like to have if they were to start childbearing afresh.

Given that ongoing family planning programmes seek to address both men and women and that men play a crucial role in the realisation of reproductive goals, the 2014 KDHS also included questions that elicited information on the fertility preferences of men.

6.1 DESIRE FOR MORE CHILDREN

Data on desire for more children can indicate future reproductive behaviour provided that the required family planning services are available, affordable, and accessible to allow people to realise their fertility preferences. Table 6.1 presents the distribution of currently married women and men by the desire for more children and according to the number of living children.

Table 6.1 shows that there is widespread desire among Kenyans to control the timing and number of births they have. Among all currently married women, almost half do not want to have another child (47 percent), and for an additional 3 percent, either they or their husband/partner are sterilised. Nearly one-third (32 percent) of married women would like to wait two years or more for their next birth, and 13 percent would like to have a child soon (within two years). The remainder are uncertain about their fertility desires (3 percent) or say they are unable to get pregnant (infecund; 1 percent). Proportions are similar among currently married men, although men tend to be slightly more pronatalist than women.

Table 6.1 Fertility preferences by number of living children

Percent distribution of currently married women and currently married men age 15-49 by desire for children, according to number of living children, Kenya 2014

Note: Totals may not add up to 100 percent because respondents with missing information are not shown separately.
na = Not applicable
[1] The number of living children includes the current pregnancy.
[2] Wants next birth within 2 years
[3] Wants to delay next birth for 2 or more years
[4] Includes both female and male sterilisation
[5] The number of living children includes one additional child if respondent's wife is pregnant (or if any wife is pregnant for men with more than one current wife).

Fertility preferences are closely related to the number of living children a person already has (Table 6.1). About three in four currently married women without a child want to have a child soon (73 percent). This proportion declines dramatically as women have more children, so that among women with three or more children, less than 10 percent want to have another child soon. The proportion of women who want no more children increases greatly after two children, from 35 percent among those with two children to 73 percent among those with five or more children. Only 3 percent of childless women say they do not want to have a child at all. These patterns are similar for men. There have been minimal changes in these numbers since the 2003 and 2008-09 KDHS surveys.

6.2 DESIRE TO LIMIT CHILDBEARING BY BACKGROUND CHARACTERISTICS

Tables 6.2.1 and 6.2.2 provide information on women's and men's desire to stop childbearing, by background characteristics. Overall, rural women are more likely than urban women to want no more children; however, this is likely associated with the finding that rural women have more children than urban women. When the number of living children is held constant, the pattern is reversed; that is, urban women are more likely than rural women to want no more children. For example, at parities between one and five, urban women are more likely to want to limit childbearing than rural women. Interestingly, at six or more children, rural women are more likely to want to limit childbearing than urban women. By region, the proportion of married women who want no more children is highest in Eastern (60 percent) and Nyanza (58 percent) and lowest in North Eastern (6 percent).

In general, fertility preferences and education are positively associated. For women with two to five children, the desire to limit childbearing increases as education increases. For women with one or no children or women with six or more children, the relationship between desire to control fertility and education is mixed. A similar pattern exists for wealth: for women with three to five children, the desire to limit childbearing increases as wealth increases. However, this pattern is not observed for women with lower or higher parities.

Note: Men who have been sterilised or who state in response to the question about desire for children that their wife has been sterilised are considered to want no more children. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] The number of living children includes one additional child if respondent's wife is pregnant (or if any wife is pregnant for men with more than one current wife).

Fertility preferences among men show similar patterns to those for women, although the overall proportions of men who do not want to have more children are lower. In terms of a rural-urban comparison, 46 percent of rural men want no more children, as compared with 38 percent of urban men. Men in the Eastern, Nyanza, and Western regions (48 percent, 47 percent, and 46 percent, respectively) are more likely to want to limit childbearing than men in other regions. The proportion of married men in North Eastern who want no more children is only 4 percent. The same relationships between fertility desires and both education and wealth that were observed for women were also observed for men.

6.3 IDEAL FAMILY SIZE

Women and men, regardless of marital status, were asked about the number of children they would choose to have if they could start afresh. Respondents who had no children were asked *If you could choose exactly the number of children to have in your whole life, how many would that be?* For respondents who had children, the question was rephrased as follows: *If you could go back to the time you did not have any children and could choose exactly the number of children to have in your whole life, how many would that be?* Responses to these questions are summarised in Table 6.3 for both men and women age 15-49.

Table 6.3 indicates that almost 98 percent each of women and men provided a numeric response. Among all women, the mean ideal family size is 3.6 children, a slight decline from 3.8 children recorded in the 2008-09 KDHS. The mean ideal family size among all men (3.9 children) is slightly higher than for women (3.6 children) and is also similar to that observed in the 2008-09 KDHS.

Ideal family size increases with the number of living children. For example, women with six or more children have an ideal family size of 5.4 children (similar to the 2008-09 KDHS ideal family size), as compared with 3.0 children for those with one child. This pattern can be attributed to two possibilities: women achieve their desired family size or women adjust their ideal number of children to be the actual number they have. Among men, the ideal family size ranges from 3.3 children for those with one child to 6.7 children for men with six or more living children.

The majority of women and men (77 percent of each) prefer two to four children, with men slightly more inclined to want three or four. Only 2 percent of women and 1 percent of men say that having one child is ideal.

[1] The number of living children includes current pregnancy for women.
[2] Means are calculated excluding respondents who gave non-numeric responses.
[3] The number of living children includes one additional child if respondent's wife is pregnant (or if any wife is pregnant for men with more than one current wife).

Table 6.4 shows the mean ideal number of children for all women age 15-49 by background characteristics. Ideal family size increases with age; for example, the mean ideal number of children for women age 15-19 is 3.2, compared with 4.5 among women age 45-49. Women in rural areas have a higher ideal family size (3.9 children) than women in urban areas (3.2 children). By region, North Eastern recorded the highest ideal family size for women (9.3 children) and Nairobi the lowest (3.0 children). Education and wealth are negatively associated with ideal family size. As education and wealth increase, ideal family size decreases. Notably, there is a large decrease in ideal family size from 7.0 children among women with no education to 3.9 children among those with at least some primary education. Similarly, there is a large decrease in ideal family size from 5.1 children among women in the lowest wealth quintile to 3.6 children among those in the second wealth quintile.

6.4 FERTILITY PLANNING

Analysis of the level of fertility planning in a society provides some insight into the degree to which couples are able to control their fertility. To measure the level of unwanted fertility, the KDHS asked women a series of questions for each child born in the preceding five years and any current pregnancy to determine whether the particular pregnancy was desired at the time ('wanted then'), not desired at the time but wanted at a later time ('wanted later'), or unwanted at any time ('wanted no more'). The questions required the respondents to accurately recall their wishes at one or more points in the last five years. Care has to be exercised in interpreting these results because an unwanted conception may well have become a cherished child, leading to the rationalisation of responses to these questions. Such rationalisation may result in an underestimate of the true extent of unwanted births.

Table 6.5 presents the percent distribution of births to women age 15-49 in the five years preceding the survey, by planning status of the birth, according to birth order and mother's age at birth. Ten percent of births in Kenya are unwanted and 25 percent are wanted later. The percentage of unwanted births increases with birth order and with the mother's age at birth. The percentage of births wanted later generally decreases with birth order and with mother's age at birth. Overall, the proportion of births considered unwanted has declined since the 2008-09 KDHS, from 17 percent to 10 percent, while the proportion of births wanted later has remained stable.

Table 6.5 Fertility planning status

Percent distribution of births to women age 15-49 in the five years preceding the survey (including current pregnancies), by planning status of the birth, according to birth order and mother's age at birth, Kenya 2014

Birth order and mother's age at birth	Planning status of birth				Total	Number of births
	Wanted then	Wanted later	Wanted no more	Missing

45-49	(40.7)	(2.0)	(57.3)	(0.0)	100.0	31
Total	64.1	25.4	10.3	0.3	100.0	10,273

Note: Figures in parentheses are based on 25-49 unweighted cases.

6.5 WANTED FERTILITY RATES

The wanted fertility rate measures the potential demographic impact of avoiding unwanted births. It is calculated in the same manner as the total fertility rate presented in Chapter 5 but excludes births classified as unwanted from the numerator. A birth is considered wanted if the number of living children at the time of conception is less than the ideal number of children reported by the respondent. The gap between wanted fertility and actual fertility shows how successful women are in achieving their reproductive intentions. This measure may also be an underestimate because women may not want to report an ideal family size that is lower than their actual family size.

The total wanted fertility rates in Table 6.6 represent the levels of fertility that would have prevailed in the three years preceding the survey if all unwanted births had been avoided. Overall, women have 1.0 child more than their ideal number (4.0 compared with 3.0). This implies that the total fertility rate is one child higher than it would be if unwanted births were avoided. The level of wanted fertility is less than the actual fertility for all background characteristics. The gap between wanted and observed fertility is greatest among women living in rural areas, those with less than a secondary education, and those in the lower wealth quintiles.

Table 6.6 Wanted fertility rates

Total wanted fertility rates and total fertility rates for the three years preceding the survey, by background characteristics, Kenya 2014

Background characteristic	Total wanted fertility rates	Total fertility rate
Residence		
Urban	2.6	3.1
Rural	3.4	4.6
Region		
Coast	3.8	4.4
North Eastern	6.4	6.7
Eastern	2.5	3.6

Wealth quintile		
Lowest	5.0	6.5
Second	3.1	4.7
Middle	2.7	4.0
Fourth	2.7	3.2
Highest	2.3	2.7
Total	3.0	4.0

Note: Rates are calculated based on births to women age 15-49 in the period 1-36 months preceding the survey. The total fertility rates are the same as those presented in Table 5.2.

FAMILY PLANNING 7

Alfred Agwanda, Abdulkadir Amin Awes, Ruth Wayua Muia

Key Findings

- Knowledge of at least one contraceptive method is universal in Kenya.
- More than half of currently married women are using a contraceptive method (58 percent).
- The most popular modern contraceptive methods used by married women are injectables (26 percent), implants (10 percent), and the pill (8 percent).
- Use of modern methods has increased over the last decade from 32 percent in the 2003 KDHS to 53 percent in 2014.
- The public sector remains the major provider of contraceptive methods; 60 percent of modern contraceptive users obtain their contraception from a government source.
- Thirty-one percent of family planning users discontinue use of a method within 12 months of starting its use. Side effects and health concerns (11 percent) are the main reason for discontinuation.
- Eighteen percent of currently married women have an unmet need for family planning services, with 9 percent in need of spacing and 8 percent in need of limiting.

7.1 INTRODUCTION

This chapter presents information on knowledge of various contraceptive methods and discusses past and current use of contraception. For users of periodic abstinence and withdrawal methods, knowledge of the ovulatory cycle is examined; for those relying on sterilisation, the timing of the procedure is assessed. Also discussed are sources of modern contraceptive methods, informed choice, discontinuation rates and reasons for discontinuation, unmet need for family planning, demand for contraception, non-use of contraception, and intention to use contraceptive methods in the future. In addition, information is provided on exposure to family planning messages through the media and contact with family planning providers. These topics are of practical use to policymakers in formulating efficient and effective family planning strategies and policies. Although the main focus of this chapter is on women, results from male respondents are also presented because men play an important role in the realisation of reproductive goals. Wherever possible, comparisons are made with findings from previous surveys in order to evaluate trends and progress made in family planning in Kenya over time.

7.2 KNOWLEDGE OF CONTRACEPTIVE METHODS

Development of a profile regarding knowledge of family planning methods was one of the objectives of the survey, because knowledge of methods is a prerequisite for making a decision to initiate contraceptive use. The 2014 KDHS collected information on knowledge of contraception by asking respondents whether or not they had heard of 10 modern methods (female sterilisation, male sterilisation, the pill, intra-uterine devices [IUDs], injectables, implants, male condoms, female condoms, lactational amenorrhoea, and emergency contraception) and two traditional methods (rhythm or calendar method and withdrawal). Provision was also made within the questionnaire to record any other methods named

spontaneously by the respondent. Most emphasis is placed on women because they bear the risk of exposure to pregnancy and most methods of contraception are designed for them.

Table 7.1 shows the level of knowledge of contraceptive methods among all women and men age 15-49. Knowledge is also presented for women and men who are currently married and who are sexually active and unmarried. Knowledge of at least one family planning method is virtually universal: 98 percent among women and 99 percent among men.

Women are more familiar with modern methods of contraception (98 percent) than with traditional methods (84 percent). Similar to results from the 2008-09 KDHS, the most widely known modern methods of contraception among women are male condoms (96 percent), injectables (95 percent), and the pill (94 percent). The least known methods among women are the lactational amenorrhoea method (LAM) (12 percent), male sterilisation (47 percent), and emergency contraception (59 percent). With regard to traditional methods, about four out of every five women (79 percent) know of the rhythm method and three out of every five (61 percent) know of the withdrawal method.

Similar to women, men are more familiar with modern than with traditional methods (99 percent compared with 86 percent), and the most widely known methods among men include male condoms (99 percent), injectables (92 percent), and the pill (92 percent). Men are more likely than women to know about male sterilisation and withdrawal, while women are more likely than men to know about IUDs, implants, and LAM. On average, women and men know about the same number of methods (mean of 8.7 for women and 8.5 for men), an increase in number and a narrowing of the gap between women and men from the 2008-09 KDHS (mean of 7.5 for women and 6.6 for men).

na = Not applicable
[1] Had last sexual intercourse within 30 days preceding the survey

Table 7.2 shows knowledge of contraceptive methods among currently married women and men age 15-49 who have heard of at least one method and who have heard of at least one modern method by background characteristics. Since knowledge of contraception is virtually universal, there is little variation in knowledge according to background characteristics. Knowledge of contraceptive methods is universal in almost all regions except North Eastern (71 percent of women and 89 percent of men). Women and men with no education demonstrated slightly less knowledge of contraceptives (88 percent and 95 percent, respectively) than women and men with at least some education (100 percent). Women and men in the lowest wealth quintile had less knowledge of contraceptive methods than those in higher wealth quintiles, although the differences are less striking among men than they are among women.

More than 95 percent of women demonstrate knowledge of at least one contraceptive method in all counties other than Mandera, Wajir, West Pokot, Garissa, Turkana, Tana River, and Marsabit. Among men, only two counties fall at or below 95 percent: Mandera and Turkana (Table 7.2C).

7.3 CURRENT USE OF CONTRACEPTION

This section presents information on the prevalence of current contraceptive use among all women, currently married women, and sexually active unmarried women age 15-49. Current use of contraceptives is the most widely employed and valuable measure of the success of family planning programmes. The contraceptive prevalence rate (CPR) is usually defined as the percentage of currently married women who are currently using a method of contraception.

Table 7.3 shows the percent distribution by age of all women, currently married women, and sexually active unmarried women who use specific family planning methods. Contraceptive methods are grouped into modern and traditional methods.

Table 7.3 Current use of contraception by age

Percent distribution of all women, currently married women, and sexually active unmarried women age 15-49 by contraceptive method currently used, according to age, Kenya 2014

Note: If more than one method is used, only the most effective method is considered in this tabulation. Figures in parentheses are based on 25-49 unweighted cases.
na = Not applicable
LAM = Lactational amenorrhoea method
[1] Women who have had sexual intercourse within 30 days preceding the survey

Nearly 6 in 10 currently married women (58 percent) are using a method of family planning. Modern methods of contraception are more commonly used (53 percent) than are traditional methods (5 percent). Of the modern methods, injectables are the most widely used (26 percent), followed by implants (10 percent) and the pill (8 percent); all other modern methods are used by 3 percent or less of married women.

Use of any contraceptive method is higher among sexually active unmarried women (65 percent) than among currently married women (58 percent). More sexually active unmarried women use modern (61 percent) than traditional (5 percent) contraceptive methods. Injectables are the most commonly used form of modern contraception for sexually active unmarried women at 22 percent, followed by male condoms at 21 percent.

Table 7.3 further shows that contraceptive use varies by age, peaking at age 30-34 among currently married women and at age 25-29 among sexually active unmarried women.

7.4 CURRENT USE OF CONTRACEPTION BY BACKGROUND CHARACTERISTICS

Analysing current use of contraception by background characteristics is important because it helps identify subgroups of the population to target for family planning services. Table 7.4 presents the percent distribution of currently married women age 15-49 by their use of family planning methods, according to background characteristics. This table allows a comparison of levels of current contraceptive use across major population groups and an examination of differences in use in the various subgroups.

Table 7.4 shows that contraceptive use is associated with the number of children a woman has. Only 15 percent of currently married women with no living children use contraception; the percentage increases to 61 percent among women with one or two children and 66 percent among women with three or four children before declining to 52 percent among women with five or more children. A higher percentage of urban women (62 percent) than rural women (56 percent) use some method of contraception, although this gap is smaller than the one observed in the 2008-09 KDHS (53 percent urban, 43 percent rural).

Note: If more than one method is used, only the most effective method is considered in this tabulation.
LAM = Lactational amenorrhoea method

Use of any method is highest in the Central (73 percent) and Eastern (70 percent) regions and lowest in the North Eastern (3 percent) and Coast (44 percent) regions. There is a noticeable increase in current use among women with at least some education and a higher degree of household wealth. Only 18 percent of currently married women with no education use contraception, while more than half of women with at least some schooling use a method (55-65 percent). Thirty-two percent of women in the lowest wealth quintile use a method of contraception, as compared with 58 percent to 66 percent of women in the higher wealth quintiles.

Twenty-two counties have a CPR above the national average (58 percent). Approximately three-quarters of currently married women use a contraceptive method in Kirinyaga (81 percent), Makueni (80 percent), Meru (78 percent), Machakos (76 percent), and Tharaka-Nithi and Kiambu (74 percent each). The counties with the lowest CPR include Mandera and Wajir (2 percent each), Garissa (6 percent), Turkana (10 percent), and Marsabit (12 percent) (Table 7.4C).

LAM = Lactational amenorrhoea method.

7.5 TRENDS IN CURRENT USE OF CONTRACEPTION

Trends in current use of family planning can be used to monitor and evaluate the success of family planning programmes over time. Table 7.5 and Figure 7.1 show trends in the use of modern contraceptives among currently married women from 2003 to 2014. Data from the three DHS surveys conducted in Kenya over the past 11 years show an impressive increase in the use of modern contraceptive methods.

Table 7.5 Trends in the current use of contraception

Percent distribution of currently married women age 15-49 by contraceptive method currently used, according to several surveys

Method	2003 KDHS	2008-09 KDHS	2014 KDHS

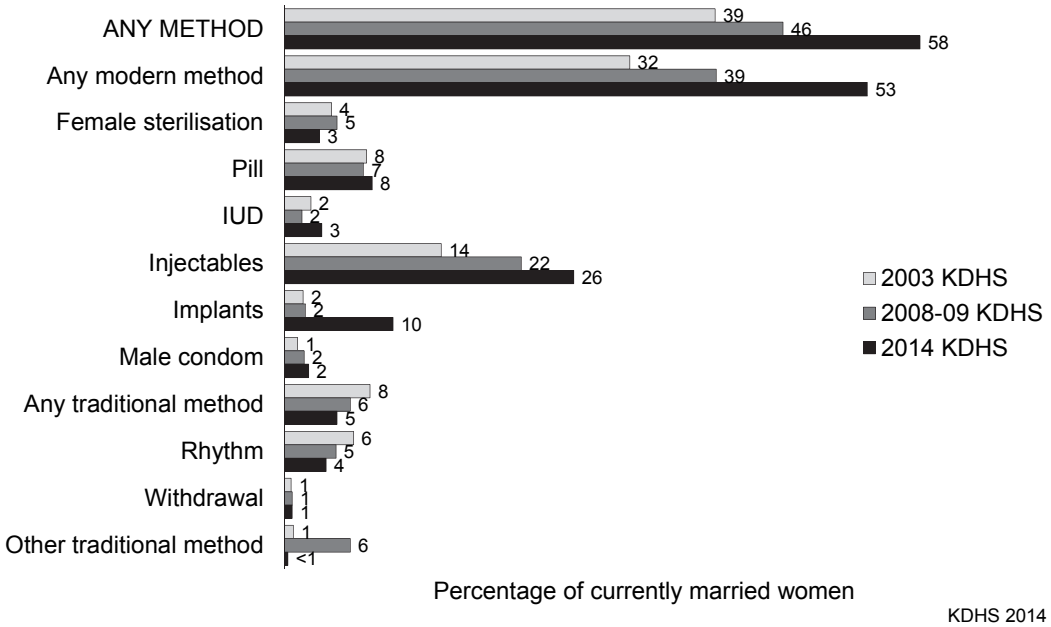
Number of women	4,919	4,928	18,549

[a] The question did not specify male condom.

Figure 7.1 **Trends in contraceptive use among currently married women**



KDHS 2014

Currently married women's use of modern contraceptives increased from 32 percent in 2003 to 39 percent in 2008-09 and again to the current 53 percent. With these increases, the government of Kenya's Population Policy for National Development has achieved its target of 52 percent of currently married women using a modern contraceptive method by 2015. While the use of modern methods has increased, uptake of traditional contraceptive methods has decreased slightly over the years (8 percent in 2003 to 5 percent in 2014). Among the various methods women use, the biggest change is reported for injectables and for implants. Currently married women's use of injectables increased from 14 percent in 2003 to the current 26 percent. Use of implants increased from 2 percent in 2003 to the current 10 percent.

7.6 TIMING OF STERILISATION

Sterilisation is a very effective permanent method of family planning. In women, it involves blocking or occluding the fallopian tubes to prevent eggs and sperm from uniting. This is one of the

options that may be adopted by couples who do not want any more children; therefore, it is important to know if the age at which women get sterilised is changing. Table 7.6 shows the percent distribution of sterilised women age 15-49 by age at the time of sterilisation and median age at sterilisation, according to the number of years since the operation. The median age at sterilisation for Kenyan women is 33.2 years, which does not differ much from the median age (33.0 years) reported in the 2008-09 KDHS.

Table 7.6 Timing of sterilisation

Percent distribution of sterilised women age 15-49 by age at the time of sterilisation and median age at sterilisation, according to the number of years since the operation, Kenya 2014

Years since operation	Age at time of sterilisation						Total	Number of women	Median age[1]
	<25	25-29	30-34	35-39	40-44	45-49			
<2	(0.0)	(18.6)	(34.9)	(30.1)	(14.1)	(2.3)	100.0	48	(33.4)
2-3	4.6	11.1	36.1	24.5	15.4	8.5	100.0	68	32.4
4-5	0.0	25.3	31.3	20.1	23.3	0.0	100.0	56	33.3
6-7	(0.0)	(8.0)	(25.4)	(59.2)	(7.5)	(0.0)	100.0	46	(36.4)
8-9	(1.0)	(12.3)	(19.9)	(63.3)	(3.5)	(0.0)	100.0	40	(36.3)
10+	8.4	32.9	42.9	15.8	0.0	0.0	100.0	81	a
Total	3.0	19.4	33.4	31.7	10.4	2.0	100.0	339	33.2

Note: Figures in parentheses are based on 25-49 unweighted cases.
a = Not calculated due to censoring
[1] Median age at sterilisation is calculated only for women sterilised before age 40 to avoid problems of censoring.

7.7 SOURCE OF CONTRACEPTION

Table 7.7 presents the main sources of contraception for users of modern methods. Information on where users obtain their contraceptive method is important for programme managers and implementers in designing family planning policies and programmes. All current users of modern contraceptive methods were asked the most recent source of their method.

The public sector is the major source of contraceptive methods in Kenya, providing contraception to 60 percent of current users. Within the public sector, 24 percent of users obtain their methods from government dispensaries, 20 percent from government hospitals, and 16 percent from government health centres. Thirty-four percent of modern contraceptive users obtain their methods from the private medical sector, mainly from private hospitals/clinics (21 percent) and pharmacies (10 percent). Sources of contraception remain stable compared with those reported in 2008-09, when 57 percent of users obtained contraception from the public sector and 36 percent from the private sector.

Except for the pill and male condoms, the public sector is the primary provider of most types of contraception used in Kenya. The majority of women who use the pill obtain it from the private sector (57 percent), and nearly half of women who use male condoms obtain them from other sources, largely from shops (39 percent). These findings point to the continued reliance on government facilities as a major source of contraceptives.

Table 7.7 Source of modern contraception methods

Percent distribution of users of modern contraceptive methods age 15-49 by most recent source of method, according to method, Kenya 2014

Source	Female sterilisation	Pill	IUD	Injectables	Implants	Male condom	Total

Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0
Number of women	691	1,703	712	5,818	2,213	975	12,131

Note: Total includes other modern methods but excludes lactational amenorrhoea method (LAM). Total includes contraceptive methods with too few users to show separately, including one user of male sterilisation and six female condom users. Totals may not add up to 100 percent because women with missing information are not shown separately.
FHOK = Family Health Organisation of Kenya

7.8 INFORMED CHOICE

Informed choice is an important principle in the delivery of family planning services. It is required that all family planning providers inform potential users about the side effects of the method and what they should do if they encounter such problems. This information assists users in making an informed decision about what contraceptive method may work best for them and in coping with side effects. By making an informed choice, users can choose the method that is right for them, and thereby decrease the likelihood that they will discontinue use of the method. Women should be informed of all methods available to them. Table 7.8 shows the percentage of current users of modern methods who were informed about side effects or problems of the method used, about what to do if they experienced side effects, and about other methods they could use. These data are also presented by method type and initial source.

Sixty percent of current users of modern contraceptive methods were informed about potential side effects of their method, 52 percent were told what to do if they experienced side effects, and 79 percent were given information about other methods. Since the 2008-09 KDHS, only one of these indicators, being informed about alternative methods (61 percent in 2008-09), has improved.

Users were slightly more likely to receive information about side effects or problems associated with a method from a government medical facility (63 percent) than from a private facility (55 percent). This pattern prevails for being informed about what to do when experiencing side effects (public sector, 56 percent; private sector, 45 percent) and being informed about alternative methods (public sector, 81 percent; private sector, 75 percent).

Table 7.8 Informed choice

Among current users of modern methods age 15-49 who started the last episode of use within the five years preceding the survey, the percentage who were informed about possible side effects or problems of that method, the percentage who were informed about what to do if they experienced side effects, and the percentage who were informed about other methods they could use, by method and initial source, Kenya 2014

	Among women who started last episode of modern contraceptive method within five years preceding the survey:			
Method/source	Percentage who were informed about side effects or problems of method used	Percentage who were informed about what to do if side effects experienced	Percentage who were informed by a health or family planning worker of other methods that could be used	Number of women
Method				
Female sterilisation	51.2	44.1	77.4	142
Pill	50.8	42.6	77.4	661
IUD	81.4	74.9	88.8	246
Injectables	55.0	46.8	75.1	2,260
Implants	71.6	64.3	85.8	1,012

Other source	**52.4**	**39.2**	**85.4**	**73**
Total	59.6	51.8	78.8	4,322

Note: Table includes users of only the methods listed individually. Total includes 39 cases for whom information about informed choice is missing. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
FHOK = Family Health Organisation of Kenya
[1] Source at start of current episode of use

7.9 CONTRACEPTIVE DISCONTINUATION RATES

Couples can realise their reproductive goals only when they use contraceptive methods consistently and correctly. Discontinuation of contraception, for reasons other than to conceive, interferes with family planning and increases the risk for unplanned pregnancies. In the "calendar" section of the Woman's Questionnaire, all segments of contraceptive use from 62 months prior to the survey are recorded. When calculating discontinuation rates, the month of the interview and the two months prior to the survey are ignored in order to avoid the bias that may be introduced by unrecognised pregnancies. Twelve-month contraceptive discontinuation rates based on the calendar data are presented in Table 7.9.

Thirty-one percent of contraceptive users discontinue use of the method within 12 months of starting its use. Discontinuation rates are highest for methods in the "other" category (e.g., female condom, LAM, withdrawal) (46 percent), followed by the pill (45 percent) and male condoms (43 percent). The lowest discontinuation rates are for IUDs (6 percent) and implants (8 percent). Users of the pill are most likely (22 percent) to switch to another method, while users of IUDs and implants are least likely to switch to another method (4 percent each). Eleven percent of episodes of discontinuation occurred because of side effects or health concerns, and 5 percent because the woman wanted to become pregnant.

Table 7.9 Twelve-month contraceptive discontinuation rates

Among women age 15-49 who started an episode of contraceptive use within the five years preceding the survey, the percentage of episodes discontinued within 12 months, by reason for discontinuation and specific method, Kenya 2014

Method	Method failure	Desire to become pregnant	Other fertility related reasons[2]	Side effects/ health concerns	Wanted more effective method	Other method related reasons[3]	Other reasons	Any reason[4]	Switched to another method[5]	Number of episodes of use[6]
Female sterilisation	(0.0)	(0.0)	(0.0)	(0.0)	(0.0)	(0.0)	(0.9)	(0.9)	(0.0)	150
Pill	5.3	6.2	4.0	15.7	6.8	2.2	4.6	44.9	21.5	1,727
IUD	0.8	0.2	0.4	4.2	0.0	0.2	0.6	6.4	3.8	298
Injectables	1.7	5.4	2.8	14.4	1.9	1.2	3.4	30.9	10.2	4,054
Implants	0.3	0.3	0.2	6.6	0.1	0.1	0.3	8.0	3.7	1,164
Male condom	1.9	5.3	21.4	0.8	2.3	0.3	10.8	42.9	4.6	859
Rhythm	9.1	4.1	3.8	0.0	6.3	0.2	1.4	24.8	6.7	661
Other[1]	9.0	10.5	2.4	5.7	9.3	2.8	6.2	45.8	15.9	243
All methods[1]	3.0	4.7	4.4	10.5	3.1	1.1	3.7	30.5	10.5	9,158

Note: Figures are based on life table calculations using information on episodes of use that began 3-62 months preceding the survey. Figures in parentheses are based on 125-249 unweighted cases.
[1] Includes female condom, LAM, withdrawal, other modern and other traditional methods
[2] Includes infrequent sex/husband away, difficult to get pregnant/menopausal, and marital dissolution/separation
[3] Includes lack of access/too far, costs too much, and inconvenient to use
[4] Reasons for discontinuation are mutually exclusive and add to the total given in this column
[5] The episodes of use included in this column are a subset of the discontinued episodes included in the discontinuation rate. A woman is considered to have switched to another method if she used a different method in the month following discontinuation or if she gave "wanted a more effective method" as the reason for discontinuation and started another method within two months of discontinuation.
[6] Number of episodes of use includes both episodes of use that were discontinued during the period of observation and episodes of use that were not discontinued during the period of observation

7.10 REASONS FOR DISCONTINUATION OF CONTRACEPTIVE USE

Table 7.10 shows the percent distribution of discontinuations of contraceptive methods in the five years preceding the survey by the main reason for discontinuation, according to method. The most common reason for discontinuing a method is health concerns or side effects (29 percent), followed by desire to become pregnant (26 percent) and pregnancy (11 percent). Health concerns or side effects are most often cited as the reason for discontinuing use of implants (52 percent), IUDs (43 percent), injectables (38 percent), and the pill (28 percent). Infrequent sex or absence of the husband is the reason most often reported for discontinuing use of the male condom (38 percent).

Table 7.10 Reasons for discontinuation

Percent distribution of discontinuations of contraceptive methods in the five years preceding the survey by main reason stated for discontinuation, according to specific method, Kenya 2014

Reason	Pill	IUD	Injectables	Implants	Male condom	LAM	Rhythm	Withdrawal	Other	All methods
Became pregnant while using	14.1	4.7	6.2	1.3	6.2	(1.5)	38.5	35.7	(16.7)	10.8
Wanted to become pregnant	23.5	24.2	29.0	24.5	16.5	(8.7)	21.8	29.2	(34.7)	25.6
Husband/partner disapproved	0.6	4.2	0.9	1.1	5.6	(0.0)	0.7	1.6	(1.9)	1.3
Wanted more effective method	12.8	4.7	4.9	2.4	9.6	(60.1)	19.4	12.4	(6.4)	8.7
Health concerns/side effects	27.6	42.9	37.6	51.5	1.2	(0.0)	0.0	3.4	(15.6)	29.0
Lack of access/too far	0.5	0.0	1.4	0.1	0.2	(0.0)	0.0	0.0	(0.0)	0.8
Cost too much	0.9	0.0	1.2	0.2	0.0	(0.0)	0.0	0.0	(0.0)	0.8
Inconvenient to use	3.5	2.2	1.2	1.1	1.4	(7.7)	0.9	2.5	(3.8)	1.9
Up to God/fatalistic	0.1	0.9	0.1	0.0	0.0	(0.0)	0.1	0.0	(0.0)	0.1

Infrequent sex/husband away	6.2	1.9	6.5	3.9	38.0	(1.3)	5.8	1.4	(8.5)	8.9
Marital dissolution/separation	1.1	0.7	1.2	4.4	0.5	(0.0)	0.1	0.6	(0.0)	1.1
Other	3.4	7.7	3.6	5.7	4.2	(14.5)	2.6	1.1	(2.9)	3.8
Don't know/missing	5.2	3.1	5.7	3.7	16.2	(6.2)	9.3	12.2	(8.3)	6.7
Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0
Number of discontinuations	1,713	119	3,394	374	624	41	541	76	72	6,961

Note: Total includes contraceptive methods with too few users to show separately, including four users of female sterilisation and three female condom users. Figures in parentheses are based on 25-49 unweighted cases.
LAM = Lactational amenorrhoea method

7.11 KNOWLEDGE OF FERTILE PERIOD

A basic understanding of the reproductive cycle is important for successful use of coitus-related methods of contraception such as the rhythm method. The successful practice of such methods depends in large part on understanding when during the ovulatory cycle a woman is most likely to conceive. All women in the survey were asked about their knowledge of a woman's fertile period. Specifically, they were asked whether there are certain days between two menstrual periods when a woman is most likely to become pregnant if she has sexual intercourse. Those who answered in the affirmative were further asked if this time is just before the period begins, during the period, right after the period ends, or halfway between the two periods.

Table 7.11 Knowledge of fertile period

Percent distribution of women age 15-49 by knowledge of the fertile period during the ovulatory cycle, according to current use of the rhythm method, Kenya 2014

Perceived fertile period	Users of rhythm method	Nonusers of rhythm method	All women
Just before her menstrual period begins	20.2	16.0	16.1
During her menstrual period	1.7	3.6	3.5
Right after her menstrual period has ended	32.6	32.3	32.3
Halfway between two menstrual periods	35.8	25.2	25.5
Other	0.0	0.2	0.2
No specific time	4.2	10.8	10.6
Don't know	5.5	11.9	11.7
Total	100.0	100.0	100.0
Number of women	425	14,200	14,625

Note: Totals may not add up to 100 percent because women with missing information are not shown separately.

Table 7.11 shows the percent distribution of women age 15-49 by knowledge of women's fertile period, according to current use of the rhythm method. Only 26 percent of all women correctly reported the most fertile time as being halfway between two menstrual periods. Among users of the rhythm method, 36 percent were able to correctly identify the fertile period, while 33 percent incorrectly reported that the fertile period is directly after menstruation has ended and 20 percent incorrectly reported that it is just before menstruation begins. These numbers do not indicate any improvement in understanding of the reproductive cycle since the 2008-09 KDHS. There is continued need for education about women's reproductive system and effective use of contraceptive methods.

7.12 NEED AND DEMAND FOR FAMILY PLANNING SERVICES

This section provides information on the extent of need and potential demand for family planning services in Kenya. Unmet need for family planning refers to fecund women who are not using contraception but who wish to postpone their next birth (spacing) or stop childbearing altogether (limiting). Specifically, women are considered to have an unmet need for spacing if they are:

- At risk of becoming pregnant, not using contraception, and either do not want to become pregnant within the next two years or are unsure if or when they want to become pregnant.
- Pregnant with a mistimed pregnancy.
- Postpartum amenorrhoeic for up to two years following a mistimed birth and not using contraception.

Women are considered to have an unmet need for limiting if they are:

- At risk of becoming pregnant, not using contraception, and want no (more) children.
- Pregnant with an unwanted pregnancy.
- Postpartum amenorrhoeic for up to two years following an unwanted birth and not using contraception.

Women who are classified as infecund have no unmet need because they are not at risk of becoming pregnant.

Women using contraception are considered to have a met need. Women using contraception who say they want no (more) children are considered to have a met need for limiting, and women who are using contraception and say they want to delay having a child, or are unsure if or when they want a (another) child, are considered to have a met need for spacing.

Unmet need, total demand, percentage of demand satisfied, and percentage of demand satisfied by modern methods are defined as follows:

Unmet need:	the sum of unmet need for spacing plus unmet need for limiting
Total demand for family planning:	the sum of unmet need plus total contraceptive use
Percentage of demand satisfied:	total contraceptive use divided by the sum of unmet need plus total contraceptive use
Percentage of demand satisfied by modern methods:	use of modern contraceptive methods divided by the sum of unmet need plus total contraceptive use

In the past, the definition of unmet need used information from the contraceptive calendar and other questions that were not included in every survey, which led to unmet need being calculated inconsistently across surveys. The revised definition uses only information that has been collected in every survey so that unmet need can be measured in the same way over time (see Bradley et al., 2012).

Table 7.12 shows need and demand for family planning among currently married women age 15-49 by background characteristics. Eighteen percent of currently married women have an unmet need for family planning, with 9 percent having an unmet need for spacing and 8 percent having an unmet need for limiting.

Fifty-eight percent of women have a met need for family planning. If all currently married women who say they want to space or limit their children were to use a family planning method, the contraceptive prevalence rate would increase to 76 percent. Currently, 77 percent of the family planning needs of married women are being met.

Unmet need is higher in rural areas (20 percent) than in urban areas (13 percent). Unmet need is highest in North Eastern (30 percent) and lowest in Central (9 percent) and Nairobi (11 percent). Unmet need decreases with increasing education; married women with no education have a higher unmet need for family planning (28 percent) than their educated counterparts (23 percent or less). Unmet need declines steadily as household wealth increases, from 29 percent in the lowest wealth quintile to 11 percent in the highest quintile.

Total demand for family planning is highest among women age 35-39 (82 percent) and lowest among women at the beginning (age 15-19) and end (age 45-49) of their reproductive years (each 61 percent). Demand for family planning does not vary much by urban-rural residence; however, there are wide variations by region. North Eastern has the lowest demand (33 percent) and Eastern the highest (83 percent). Women with no education (47 percent) and women in the lowest wealth quintile (60 percent) have a lower demand than their more educated or wealthier counterparts.

Table 7.12 Need and demand for family planning among currently married women

Percentage of currently married women age 15-49 with unmet need for family planning, percentage with met need for family planning, the total demand for family planning, and the percentage of the demand for contraception that is satisfied, by background characteristics, Kenya 2014

Background characteristic	Unmet need for family planning			Met need for family planning (currently using)			Total demand for family planning[1]			Percentage of demand satisfied[2]	Percentage of demand satisfied by modern methods[3]	Number of women

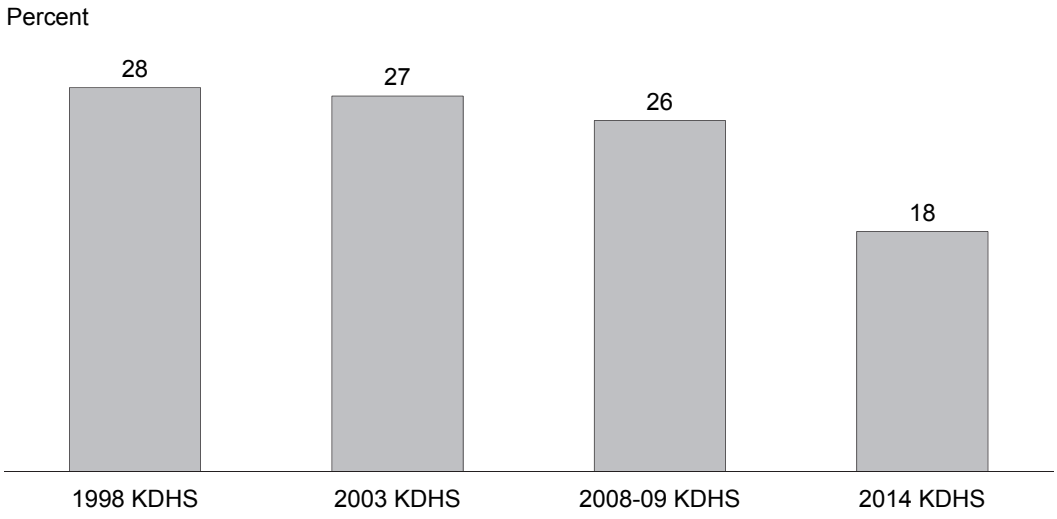
Total	9.2	8.3	17.5	25.3	32.7	58.0	34.5	41.0	75.5	76.8	70.7	8,710

Note: Numbers in this table correspond to the revised definition of unmet need described in Bradley et al., 2012.
[1] Total demand is the sum of unmet need and met need
[2] Percentage of demand satisfied is met need divided by total demand
[3] Modern methods include female sterilisation, male sterilisation, pill, IUD, injectables, implants, male condom, female condom, and lactational amenorrhoea method (LAM)

Figure 7.2 shows that unmet need decreased only marginally from 1998 (28 percent) to 2008-09 (26 percent) before a more substantial decrease to the current 18 percent.

Figure 7.2 Trends in unmet need for family planning



Note: Estimates for all years are based on the revised definition of unmet need. Data collected before 2003 exclude North Eastern region and several northern districts in the Eastern and Rift Valley.

7.13 FUTURE USE OF CONTRACEPTION

An important indicator of the changing demand for family planning is the extent to which nonusers plan to use contraceptive methods in the future. In the 2014 KDHS, currently married women age 15-49 who were not using any contraceptive method at the time of the survey were asked about their intention to use family planning in the future. Women who stated that they did not intend to use a contraceptive method in the future were also asked the reason behind this intention.

Table 7.13 shows that among currently married women not using contraception, 57 percent intend to use a family planning method in the future, 4 percent are unsure of their intentions, and 38 percent have no intention of using any method in the future. These data do not indicate any change from 2008-09. The proportion of women intending to use family planning peaks at 69 percent among nonusers with one child and declines to 45 percent among those with four or more children.

Table 7.13 Future use of contraception

Percent distribution of currently married women age 15-49 who are not using a contraceptive method by intention to use in the future, according to number of living children, Kenya 2014

	Number of living children[1]					
Intention	0	1	2	3	4+	Total
Intends to use	64.9	68.8	68.3	58.4	45.4	57.3

Number of women	231	626	708	616	1,475	3,656

[1] Includes current pregnancy

Table 7.14 presents the distribution of currently married nonusers who do not intend to use a contraceptive method in the future by the main reason why they do not intend to use. Method-related reasons, especially fear of side effects (17 percent) and health concerns (12 percent), were commonly cited reasons for not intending to use family planning in the future. Fertility-related reasons were also common, including menopause (13 percent), desire for many children (9 percent), and infrequent sex (9 percent). Religious prohibition and opposition to use each accounted for 9 percent of women's reasons for not intending to use a family planning method in the future.

Table 7.14 Reason for not intending to use contraception in the future

Percent distribution of currently married women age 15-49 who are not using contraception and who do not intend to use in the future by main reason for not intending to use, Kenya 2014

Reason	Total
Fertility-related reasons	
Infrequent sex/no sex	8.7
Menopausal/had hysterectomy	12.5
Subfecund/infecund	5.7

Total	100.0
Number of women	1,398

7.14 EXPOSURE TO FAMILY PLANNING MESSAGES

The media play an important role in communicating messages about family planning. In assessing the reach of family planning messages, the 2014 KDHS asked women and men age 15-49 whether they had heard or seen a message about family planning on the radio, on television, or in a newspaper or magazine in the last few months before the survey (Table 7.15).

Most women (75 percent) and men (82 percent) hear family planning messages on the radio; 46 percent of women and 58 percent of men hear messages on television. A lower proportion of women (29 percent) and men (43 percent) access family planning messages through a magazine or newspaper. In general, men are more exposed to family planning messages via mass media than women. One out of five women (20 percent) and about one in 10 men (13 percent) have not been exposed to family planning messages through any media. This trend has not changed substantially since the 2008-09 KDHS.

Not surprisingly, women and men residing in urban areas are much more likely to have been exposed to family planning messages in any media than their rural counterparts. Twenty-six percent of rural women have had no exposure compared with 11 percent of urban women, and 17 percent of rural men have had no exposure compared with 7 percent of urban men. Education has a positive influence on media exposure. For example, 69 percent of uneducated women have no exposure to family planning information in any form of mass media, as compared with only 9 percent among those with a secondary or higher education. A similar pattern is observed for men. Among both women and men, exposure to family planning messages via media increases with increasing household wealth.

Table 7.15 Exposure to family planning messages

Percentage of women and men age 15-49 who heard or saw a family planning message on radio, on television or in a newspaper or magazine in the past few months, according to background characteristics, Kenya 2014

Background characteristic	Women					Men

7.15 CONTACT OF NONUSERS WITH FAMILY PLANNING PROVIDERS

When family planning providers visit women in their households or when women visit health facilities, family planning fieldworkers and health providers are expected to discuss reproductive health needs and available contraceptive options and to counsel women on adopting a method of family planning. To get insight into the level of contact between nonusers and health workers, women age 15-49 who were not using contraception were asked if they had been visited by a fieldworker during the 12 months preceding the survey and if, during that visit, they had discussed family planning issues. In addition, women were asked whether they had visited a health facility in the 12 months preceding the survey for any reason and whether anyone at the facility had discussed family planning with them during the visit. This information is especially useful for determining if nonusers of family planning are being reached by family planning programmes.

Table 7.16 shows that only 6 percent of nonusers during the 12 months preceding the survey were visited by a fieldworker who discussed family planning. Only 14 percent of nonusers who had visited a health facility discussed family planning at the facility (45 percent visited a facility and did not discuss family planning). Overall, 82 percent of nonusers did not discuss family planning with a fieldworker or while visiting a health facility in the past 12 months, indicating missed opportunities to inform and educate women about family planning. These data show a slight improvement in opportunities to discuss family planning in these specific scenarios compared with the 2008-09 KDHS (88 percent).

Table 7.16 Contact of nonusers with family planning providers

Among women age 15-49 who are not using contraception, the percentage who during the past 12 months were visited by a fieldworker who discussed family planning, the percentage who visited a health facility and discussed family planning, the percentage who visited a health facility but did not discuss family planning, and the percentage who did not discuss family planning either with a fieldworker or at a health facility, by background characteristics, Kenya 2014

Background characteristic	Percentage of women who were visited by fieldworker who discussed family planning	Percentage of women who visited a health facility in the past 12 months and who:		Percentage of women who did not discuss family planning either with fieldworker or at a health facility	Number of women
		Discussed family planning	Did not discuss family planning

This low level of contact of nonusers with family planning providers varies little by background characteristics. However, adolescents are least likely to have discussed family planning either with a fieldworker or at a health facility.

7.16 MEN'S KNOWLEDGE OF AND ATTITUDES TOWARDS CONTRACEPTIVE USE

Use of family planning methods is facilitated when couples discuss and agree on the issue. To assess the extent to which women use contraception without telling their partners, married women interviewed in the 2014 KDHS were asked whether their husbands or partners knew that they were using a method of family planning. Table 7.17 shows that 92 percent of currently married women reported that their husbands/partners knew they were using a method of family planning. There is no notable variation in husbands/partners' knowledge of use of a family planning method by age or residence; however, a substantially lower proportion of women in the North Eastern region (53 percent) than in the other regions (88 percent or more) report that their husband/partner knows they are using a method of family planning. Husbands/partners' knowledge increases gradually with increasing women's education and household wealth.

Table 7.17 Husband/partner's knowledge of women's use of contraception

Among currently married women age 15-49 who are using a method, percent distribution by whether they report that their husbands/partners know about their use, according to background characteristics, Kenya 2014

[1] Includes women who report use of male sterilisation, male condoms, or withdrawal

Additionally, men were asked whether they agreed or disagreed with two statements about family planning use: (1) contraception is women's business and a man should not have to worry about it, and (2) women who use contraception may become promiscuous. The results in Table 7.18 indicate that only 13 percent of men believe that contraception is solely women's business, while 29 percent believe that women who use family planning may become promiscuous. A higher percentage of divorced, separated, and widowed men agree with the above two statements than their married and never-married counterparts. Accepting views on contraception are more likely to be expressed by men with a secondary or higher education, and such views increase with increasing household wealth.

INFANT AND CHILD MORTALITY 8

Ben Obonyo Jarabi, Andrew A. Imbwaga, John Anampiu

Key Findings

- The infant mortality rate is 39 deaths per 1,000 live births, and under-5 mortality is 52 deaths per 1,000 live births. At these levels, about one in every 26 Kenyan children dies before reaching age 1, and about one in every 19 does not survive to his or her fifth birthday.
- All early childhood mortality rates declined between the 2003 and 2014 KDHS surveys. Neonatal mortality has exhibited the slowest rate of decline (33 percent).
- A child born in the Nyanza region is almost twice as likely to die before age 5 as a child born in the Central region. Nairobi has the second highest under-5 mortality rate, following Nyanza (72 deaths per 1,000 live births).
- Male children are more likely than female children to die during their first year of life (44 deaths versus 37 deaths per 1,000 live births). Once past infancy, male and female children 1-4 years of age experience the same level of mortality (16 deaths per 1,000 live births).
- The neonatal mortality rate for the five years preceding the survey is 22 deaths per 1,000 live births, 1.4 times the postneonatal rate.
- The perinatal mortality rate for the same reference period is 29 deaths per 1,000 pregnancies.

This chapter presents levels, trends, and differentials in early childhood mortality and, among women in Kenya, high-risk fertility behaviour. This information is relevant for the planning and evaluation of health policies and programmes, and it serves the needs of the health sector by identifying vulnerable groups that are at high risk for early childhood deaths. Infant and child mortality rates are also regarded as indices that reflect the degree of poverty and deprivation of a population. Under-5 and infant mortality rates are two indicators used to monitor child health under Millennium Development Goal (MDG) 4. The government of Kenya is undertaking a number of interventions aimed at reducing childhood mortality. Targets for these programmes, including the Vision 2030 indicators and Sustainable Development Goals (SDGs), rely on data from census and from household surveys, such as the KDHS. The data presented in this chapter will contribute to planning and assessment of the progress of those interventions.

In the 2014 KDHS, data for child mortality estimations were collected in the birth history section of the Woman's Questionnaire. The birth history section began with questions about the respondent's experience with childbearing (i.e., the number of sons and daughters she has given birth to, the number who are alive, and the number who have died). These questions were followed by a retrospective birth history in which the respondent was asked to list chronologically each of her births, starting with the first one. For each birth, data were obtained on sex, month and year of birth, survivorship status, and current age or, if the child had died, the age at death. This information was used to directly estimate early childhood mortality rates. Because the primary causes of childhood mortality change as children age—from biological factors to environmental factors—childhood mortality rates are expressed by age categories and are defined as follows:

Neonatal mortality (NN):	the probability of dying within the first month of life
Postneonatal mortality (PNN):	the difference between infant and neonatal mortality
Infant mortality ($_1q_0$):	the probability of dying before the first birthday
Child mortality ($_4q_1$):	the probability of dying between the first and the fifth birthday
Under-5 mortality ($_5q_0$):	the probability of dying between birth and the fifth birthday

All rates are expressed per 1,000 live births except for child mortality, which is expressed per 1,000 children surviving to age 12 months.

8.1 DATA QUALITY

The quality of mortality estimates can be affected by both sampling and nonsampling error. Estimates of sampling error can be found in Appendix B. Nonsampling error is affected by the accuracy with which births and deaths are reported and recorded and the completeness with which births and deaths are reported.

Nonsampling error arises from problems occurring during the collection or processing of mortality data. Specifically, the reliability of mortality estimates depends upon full reporting of children who have died, the absence of differential displacement of birth dates of surviving and dead children, and accurate information on ages at death. Although the nonsampling error associated with the KDHS mortality data cannot be evaluated statistically, Appendix C includes several tables that can be used to assess the extent to which the KDHS mortality data may be subject to common reporting errors.

When age at death is misreported or misrecorded, this may distort the age pattern of mortality, especially if the net effect of the age misreporting results in children moving from one age group to another. For example, a net transfer of deaths from under one month to a higher age range will affect the estimates of neonatal and postneonatal mortality.

Displacement of dates of birth can distort mortality trends. This can occur if an interviewer knowingly recorded a death as occurring in a different year, which may happen if an interviewer were trying to cut down on overall workload because live births occurring during the five years preceding the interview are the subject of a lengthy set of additional questions. In the 2014 KDHS questionnaire, the cut-off for asking these questions was January 2009. For possible misreporting of children's birth dates, the results are shown in Appendix Table C.4. The calendar year ratios for living and deceased children are 86 and 78, respectively, for 2009, compared with 113 and 118, respectively, in 2008. This suggests some level of transference of births from 2009 to the previous year. This pattern has also been observed in the previous KDHS surveys and could be due to some interviewers transferring births out of the five-year reference period to reduce their workload.

Another potential data quality problem is selective omission from the birth histories of the births of infants who did not survive, which can lead to underestimation of mortality rates. These omissions may occur when mothers are reluctant to discuss their dead children because of grief or cultural stigma surrounding discussing such deaths. When selective omission of childhood deaths occurs, it is usually most pronounced for deaths occurring early in infancy. One way such omissions can be detected is by examining the proportion of neonatal deaths to infant deaths. Generally, if there is substantial underreporting of deaths, the result is an abnormally low ratio of neonatal deaths to infant deaths. Appendix Table C.5 does not show any sign of severe underreporting of early neonatal deaths at the national level. For the five-year period before the survey, the proportion of neonatal deaths occurring in the first week of life is 71 percent, slightly lower than that recorded in the 2008-09 KDHS (82 percent) but

within the expected range.[1] Moreover, this ratio is approximately stable over the 20 years preceding the survey, a further indication that early infant deaths have not been grossly underreported.

Examination of the 2014 KDHS infant death data shows that the proportion of neonatal to infant deaths ranges from 59 percent in the period 0 to 4 years prior to the survey to 46 percent during the period 15 to 19 years before the survey (Table C.6). This pattern conforms to the expectation that, as mortality levels decline, a larger proportion of infant deaths will take place during the early neonatal period. Although slightly lower than that in the 2008-09 KDHS (61 percent), the 59 percent observed in 2014 is higher than those recorded in the 2003 (47 percent) and the 1998 (41 percent) KDHS surveys, an indication that underreporting of deaths was minimal. This high percentage of neonatal deaths implies that there was little if any selective omission of childhood deaths that could compromise the quality of the 2014 KDHS early childhood mortality rates.

Another potential data quality problem is heaping of the age at death. Errors in the reporting of the age at death may result in the transference of deaths from one age bracket for which mortality rates are being calculated to another. For example, heaping on age 1 year or 12 months can result in an underestimate of the infant mortality rate and an overestimate of the child mortality level. Several steps were taken in the training of the KDHS interviewers and in the structuring of the KDHS birth history to reduce errors in reporting the age at death. Interviewers were instructed to record age at death in days if the child died during the first month of life. They were to record age at death in months if the child died in the first two years of life. Because heaping on "1 year" or "12 months" is very common, interviewers were asked specifically to probe when the mothers gave these responses. The distribution of deaths under two years during the 20 years prior to the survey by age at death in months can show if there is heaping at age 12 months during any of the periods before the survey, with corresponding deficits in adjacent months. Table C.6 shows that there are 256 reported deaths at 12 months compared with 46 deaths at 11 months, 30 deaths at 13 months, and 33 deaths at 14 months. This is likely to somewhat underestimate infant mortality and overestimate child mortality. However, this will have minimal effect on the mortality estimates for the period 0 to 4 years before the survey since heaping of deaths at age 12 months is much less pronounced in the most recent period of 0 to 4 years prior to the survey (37 deaths) than in the periods of 5-9 years, 10-14 years, and 15-19 years prior to the survey (49-77 deaths).

In addition to recall errors for the more distant retrospective periods, there are structural reasons for limiting mortality estimation to recent periods, preferably to the periods 0-4, 5-9, and 10-14 years before the survey. In fact, the periods other than the first (0-4 years) have slightly biased estimates because they are based on the child mortality experiences of women age 15-44 and 15-39, respectively, instead of women age 15-49 as in the period 0-4 years preceding the survey. Therefore, estimating mortality for periods more than 10-14 years before the survey is not advisable.

In summary, while there is evidence of some omission or displacement of infant deaths from one period to another, infant deaths in the 2014 KDHS do not appear to be severely underreported.

8.2 LEVELS AND TRENDS IN INFANT AND CHILD MORTALITY

Table 8.1 shows neonatal, postneonatal, infant, child, and under-5 mortality rates for three successive five-year periods before the survey. For the five years immediately preceding the 2014 KDHS (approximate calendar years 2010-2014), the infant mortality rate is 39 deaths per 1,000 live births and the under-5 mortality rate is 52 deaths per 1,000 live births. This implies that about one in every 26 children born in Kenya dies before age 1, while one in every 19 does not survive to age 5. Neonatal mortality is 22 deaths per 1,000 live births during the same period, while postneonatal mortality is 16 deaths per 1,000 live births. Fifty-six percent of infant deaths in Kenya occur during the first month of life.

[1] There are no models for mortality patterns during the neonatal period. However, one review of data from several developing countries concluded that, at neonatal mortality levels of 20 per 1,000 or higher, approximately 70 percent of neonatal deaths occur within the first six days of life (Boerma, 1988).

Table 8.1 Early childhood mortality rates

Neonatal, postneonatal, infant, child, and under-5 mortality rates for five-year periods preceding the survey, Kenya 2014

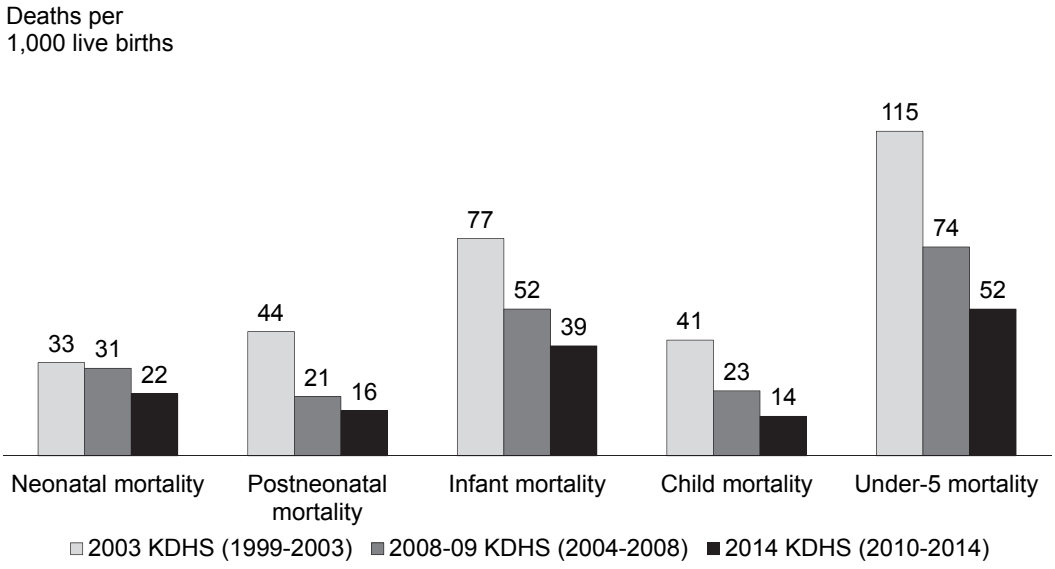
Years preceding the survey	Approximate calendar years	Neonatal mortality (NN)	Postneonatal mortality (PNN)[1]	Infant mortality ($_1q_0$)	Child mortality ($_4q_1$)	Under-5 mortality ($_5q_0$)
0-4	2010-2014	22	16	39	14	52
5-9	2005-2009	24	19	43	18	60
10-14	2000-2004	26	26	51	30	80

[1] Computed as the difference between the infant and neonatal mortality rates

The 2014 KDHS documents a pattern of decreasing under-5 mortality during the 15 years prior to the survey. Results from the three recent KDHS surveys conducted between 2003 and 2014 show a similar decline in childhood mortality over the past 15 years (Figure 8.1).

Comparing data for the five-year period preceding each of the three KDHS surveys, under-5 mortality declined from 115 deaths per 1,000 live births in 1999-2003 to 74 deaths per 1,000 in 2004-08, and further decreased by 30 percent to 52 deaths per 1,000 in the five years preceding the 2014 KDHS. The infant mortality rate similarly declined from 77 deaths per 1,000 deaths in 1999-2003 to 52 deaths per 1,000 in 2004-08, and it declined further by 25 percent to 39 deaths per 1,000 in the five years preceding the 2014 KDHS. Postneonatal mortality has also steadily declined, from 44 deaths to 21 deaths per 1,000 live births between 1999-2003 and 2004-08, and then to 16 deaths per 1,000 in the five years preceding 2014, a 24 percent decrease in the past five years. Similar declines are observed for neonatal and child mortality rates.

Figure 8.1 **Trends in childhood mortality, 1999-2014**



The observed trends imply that the increase in mortality witnessed in the 1990s has potentially reversed (Opiyo and Sawhney, 2014; Wafula et al., 2012). These findings are consistent with and may be related to other improved health outcomes and behaviours presented elsewhere in this report, including improvements in utilisation of maternal health care services, such as deliveries in a health facility, deliveries by a skilled health provider, and uptake of postnatal care services for mothers and newborns (Chapter 9); improved health care seeking behaviour for childhood illnesses such as pneumonia, diarrhoea, and malaria (Chapter 10); and increased levels of ownership and use of insecticide-treated mosquito nets (Chapter 12). The decline in childhood mortality reflects the recent global trend of under-5 mortality reducing faster than at any other time in the past two decades (UNICEF, 2014).

However, accelerated change for child survival, health, and development needs more focus on a healthy start of life. The neonatal mortality rate of 22 deaths per 1,000 live births indicates that progress remains to be made before Kenya achieves the Every Newborn Action Plan's goal of a neonatal mortality rate below 10 deaths per 1,000 live births by 2035 (UNICEF, 2014).

8.3 SOCIOECONOMIC DIFFERENTIALS IN INFANT AND CHILD MORTALITY

The probability of dying in early childhood is higher in some population subgroups than in others. Table 8.2 and Figure 8.2 show differentials in early childhood mortality rates by residence, region, level of mother's education, and household wealth. The childhood mortality rates by background characteristics are calculated for the 10-year period before the survey (approximately 2005-2014) so that the estimates are based on a sufficient number of births in each category to study mortality differentials across subgroups.

While postneonatal and child mortality are slightly lower in urban areas than in rural areas, neonatal mortality is 24 percent higher in urban areas than it is in rural areas (26 deaths versus 21 deaths per 1,000 live births).

Table 8.2 Early childhood mortality rates by socioeconomic characteristics

Highest	26	13	38	9	47

[1] Computed as the difference between the infant and neonatal mortality rates

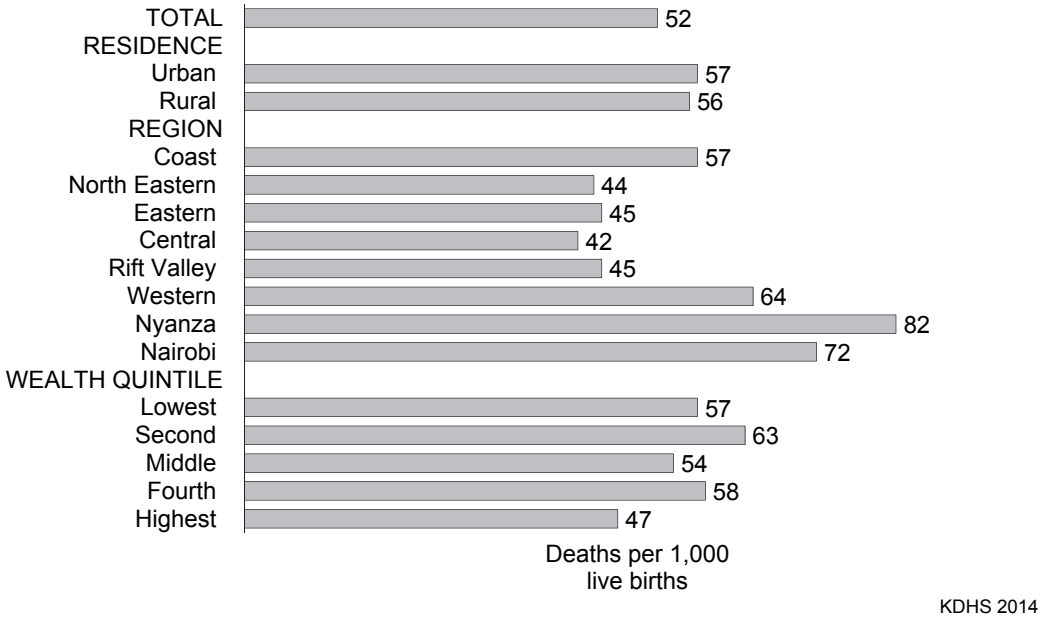
The under-5 mortality rate summarises the mortality rate from birth to age 5. As is true in each of its component rates, the under-5 mortality differentials are most pronounced across regions. The range in under-5 mortality ranges from a low of 42 deaths per 1,000 live births in Central region to a high of 82 deaths per 1,000 live births in Nyanza. Nairobi has the second highest under-5 mortality rate.

Focusing on the component parts of under-5 mortality, the highest infant mortality is experienced in Nairobi and Nyanza (55 and 50 deaths per 1,000 live births). The highest neonatal mortality is experienced in Nairobi (39 deaths per 1,000 live births) and the highest postneonatal mortality is experienced in Nyanza region (31 deaths per 1,000 live births). Nyanza also has the highest child mortality rate (33 deaths per 1,000 live births), followed by Western region (25 deaths per 1,000 live births).

The highest under-5 mortality rate by education is among those born to mothers with an incomplete primary education (63 deaths per 1,000 live births). Children in these households experience both the highest postneonatal and child mortality (20 and 22 deaths per 1,000 live births).

While infants born into the wealthiest households experience the lowest levels of both postneonatal and child mortality, they, along with the second wealthiest households (fourth wealth quintile), experience the highest neonatal mortality. The highest child mortality occurs in households in the second wealth quintile (63 deaths per 1,000 live births).

Figure 8.2 **Under-5 mortality by background characteristics**



8.4 DEMOGRAPHIC DIFFERENTIALS IN INFANT AND CHILD MORTALITY

The demographic characteristics of both mother and child play an important role in the survival of children. Table 8.3 presents early childhood mortality rates for the 10-year period preceding the survey by demographic characteristics (i.e., sex of child, mother's age at birth, birth order, previous birth interval, and birth size).

Male children are more likely than female children to die during their first year of life (44 deaths versus 37 deaths per 1,000 live births). Once past infancy, male and female children one to four years of age experience the same level of mortality (16 deaths per 1,000 live births).

Both mother's age at the time of the birth of the child and the child's birth order exhibit a U-shaped association with neonatal mortality. Babies born to the youngest and oldest mothers experience the highest neonatal mortality rates, as do babies born after the shortest and longest birth intervals.

Shorter birth intervals have been demonstrated to be associated with higher mortality, both during and after infancy. Kenya follows suit with a strong association as well during neonatal, postneonatal, and child portions of life. Babies born after the shortest birth intervals, less than two years, are nearly twice as likely to die (83 deaths per 1,000 live births) as babies born after three (42 deaths per 1,000 live births) or four or more years (44 deaths per 1,000 live births). An anomaly to this pattern is the higher neonatal mortality of births born after four or more years as compared with births born after an interval of two or three years; a further analysis that accounts for other co-factors of mortality might elucidate why this is so.

Table 8.3 Early childhood mortality rates by demographic characteristics

[3] Rates for the five-year period before the survey

The 2014 KDHS reports size at birth according to the size of the baby as gauged by the mother. Women were asked: *When (NAME) was born, was he/she very large, larger than average, average, smaller than average, or very small?* Children whose birth size is small or very small are more than two times as likely to die during the first month of life as children whose birth size is average or larger (41 deaths per 1,000 live births versus 17 deaths per 1,000 live births).

8.5 PERINATAL MORTALITY

Perinatal mortality is a good indicator of the state of health in general and the health status of the mother at the time of delivery. Pregnancy losses occurring after seven completed months of gestation (stillbirths) plus deaths to live births within the first seven days of life (early neonatal deaths) constitute perinatal deaths. The distinction between a stillbirth and an early neonatal death may be a fine one, often depending on observing and then remembering sometimes faint signs of life after delivery. The causes of stillbirths and early neonatal deaths are closely linked, and examining just one or the other can understate the true level of mortality at or near the time of delivery. For this reason, deaths around delivery are combined into the perinatal mortality rate, defined as the number of perinatal deaths per 1,000 pregnancies reaching seven months of gestation.

Table 8.4 presents the number of stillbirths and early neonatal deaths and the perinatal mortality rate for the five-year period preceding the 2014 KDHS, by background characteristics. Of the 9,484 reported pregnancies of at least seven months' duration, 126 ended in stillbirths and 146 were neonatal deaths, thus giving a perinatal mortality rate of 29 deaths per 1,000 pregnancies, a decline from the 37 deaths per 1,000 pregnancies reported in the 2008-09 KDHS.

Babies born to mothers in their 20s experience the lowest perinatal mortality rate (22 deaths per 1,000 pregnancies). The shortest of birth intervals, those less than 15 months in duration, experience the highest perinatal mortality rates of all birth interval lengths (37 deaths per 1,000 pregnancies). There is no difference in the perinatal mortality rate by urban-rural residence, similar to the findings in the 2003 and

2008-09 KDHS surveys. There are regional variations in the level of perinatal mortality, although the results should be interpreted with caution. The North Eastern region has the lowest perinatal mortality rate (16 deaths per 1,000 pregnancies) and the Eastern region the highest (44 deaths per 1,000 pregnancies). However, the small number of pregnancies of at least seven months' gestation in North Eastern should be kept in mind when interpreting these data.

There is no strong pattern of association between perinatal mortality rates and mother's education status or household wealth. The rate is highest among children whose mothers have a complete primary education (33 deaths per 1,000 pregnancies) and children in the second wealth quintile (34 deaths per 1,000 pregnancies).

[1] Stillbirths are foetal deaths in pregnancies lasting seven or more months.
[2] Early neonatal deaths are deaths at age 0-6 days among live-born children.
[3] The sum of the number of stillbirths and early neonatal deaths divided by the number of pregnancies of seven or more months' duration, expressed per 1,000
[4] Categories correspond to birth intervals of <24 months, 24-35 months, 36-47 months, and 48+ months.

8.6 HIGH-RISK FERTILITY BEHAVIOUR

The survival of infants and children depends in part on the demographic and biological characteristics of their mothers. Because the probability of dying in early childhood is typically much greater if children are born to mothers who are too young (under age 18) or too old (over age 34), if they are born after a short birth interval (less than 24 months after the preceding birth), or if they are born to

mothers with high parity (birth order four or higher), the risk of mortality is examined for births occurring in each of these categories and for births occurring under a combination of these categories. Table 8.5 shows three different measures related to risk that are meaningful to interpret together.

The first data column presents the percent distribution of births in the five years preceding the survey by risk category. Since no birth carries zero risk, the lowest risk categories are classified into two groups: births not in any high-risk category and births in an unavoidable risk category. The births that are not in any high-risk category are those that meet all of these criteria: they are born to women between age 18 and 34, they follow a birth interval of longer than 24 months, and they are of second or third birth order. Those in the unavoidable risk category are first-order births to women between age 18 and 34.

The second column in Table 8.5 denotes the relationship between the risk factors and mortality. The risk ratio compares each risk category with the "not in any high risk" category. Being in multiple risk categories usually places a baby at a higher risk of dying than does being in any one single risk category.

The last column in Table 8.5 looks to the future and addresses the question of what proportion of currently married women have the potential for having a high-risk birth. Results were obtained by classifying a currently married woman into the risk category she would fall into if she were to become pregnant at the time of the survey.

Table 8.5 High-risk fertility behaviour

Percent distribution of children born in the five years preceding the survey by category of elevated risk of mortality and the risk ratio, and percent distribution of currently married women by category of risk if they were to conceive a child at the time of the survey, Kenya 2014

	Births in the 5 years preceding the survey		Percentage of currently married women[1]
Risk category	Percentage of births	Risk ratio	
Not in any high risk category	30.3	1.00	25.6[a]
Unavoidable risk category			
First order births between ages 18 and 34 years	21.0	1.34	4.5
Single high-risk category			
Mother's age <18	5.7	0.95	0.3
Mother's age >34	1.6	0.72	5.4
Birth interval <24 months	6.4	0.93	9.1
Birth order >3	19.4	0.96	16.7
Subtotal	33.1	0.94	31.5
Multiple high-risk category			
Age <18 and birth interval <24 months[2]	0.4	2.90	0.1
Age >34 and birth interval <24 months	0.1	*	0.3
Age >34 and birth order >3	8.8	1.31	26.5
Age >34 and birth interval <24 months and birth order >3	1.2	1.84	3.2
Birth interval <24 months and birth order >3	5.1	1.95	8.2
Subtotal	15.6	1.60	38.3
In any avoidable high-risk category	48.7	1.15	69.9
Total	100.0	na	100.0
Number of births/women	19,564	na	18,549

Note: Risk ratio is the ratio of the proportion dead among births in a specific high-risk category to the proportion dead among births not in any high-risk category. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
na = Not applicable
[1] Women are assigned to risk categories according to the status they would have at the birth of a child if they were to conceive at the time of the survey: current age less than 17 years and 3 months or older than 34 years and 2 months, latest birth less than 15 months ago, or latest birth being of order 3 or higher.
[2] Includes the category age <18 and birth order >3
[a] Includes sterilised women

Nationally, only 3 in 10 births were in no high-risk birth category at the time they occurred, and 2 in 10 fell into the unavoidable risk category. The other 49 percent were high-risk births, of whom 33 percent were in a single risk category and 16 percent were in more than one risk category. The most common single risk category is being of birth order four or higher, with about one in five births born in the preceding five years falling into this category. The most common multiple risk category is being of birth order four or higher and being born to a mother over age 34; 9 percent of births fell in this category.

Births born into just one single high-risk mortality category actually experienced lower mortality rates (an average risk ratio of 0.94) than births not born into any high-risk category. It is in the situation of being in multiple risk categories that births experience higher mortality levels. Births born to women less than age 18 and born less than 24 months after the preceding birth are at nearly three times the risk of dying as compared with births born to women who are not in any high-risk category (risk ratio of 2.90). It is, of course, an unusual scenario; less than 1 percent of births were born into this category. Those who experience nearly double the risk of mortality (risk ratio of 1.95), are those births that are above birth order three, born after a birth interval of less than 24 months.

The most common multiple risk category among women is being over age 34 and having already given birth to at least three children. One-quarter of women fall in this category, and births born to women in this category experience 30 percent higher mortality than births born to women who are not in any high-risk category (risk ratio of 1.31).

Nationally, 70 percent of currently married women are in a high-risk birth category, such that if they had given birth at the time of the survey, their baby would have been in a high-risk situation. Thirty-two percent of women, and thus their births, would fall into a single high-risk category, while 38 percent would fall into multiple high-risk categories.

MATERNAL HEALTH 9

Ruth Wayua Muia, Andolo Miheso, Annah W. Wamae, James N. Munguti

Key Findings

- Ninety-six percent of women with a live birth in the five years preceding the survey received antenatal care from a skilled provider, an improvement from 92 percent in the 2008-09 KDHS and 88 percent in the 2003 KDHS.
- Fifty-eight percent of women make the recommended four or more antenatal care visits during their pregnancy, an increase of 11 percentage points from the 2008-09 KDHS (47 percent).
- Sixty-one percent of live births in the five years preceding the survey were delivered in a health facility; 62 percent were assisted by a skilled provider.
- More than half (53 percent) of women who gave birth in the two years before the survey received a postnatal care checkup in the first two days after delivery.
- Thirty-six percent of infants born in the two years before the survey had their first postnatal checkup within the first two days after birth. One in three newborns received postnatal care from a doctor, a nurse, or a midwife.
- More than half (54 percent) of the women interviewed in the survey had heard of fistula. However, only 1 percent of these women reported having ever experienced fistula-like symptoms.

The health status of mothers and children is an important indicator of the overall economic health and well-being of a country (United Nations, 2010). Maternal health is inextricably linked with the survival of newborns. For every woman who dies, another 30 suffer long-lasting injuries and illnesses such as obstetric fistula (UNDP, WHO, UNFPA, and World Bank, 2006). The International Conference on Population and Development, held in Cairo, Egypt, in 1994, called for the development of comprehensive reproductive health policies, programmes, and implementation plans (UNFPA, 1994). This call defined the focus of the Kenya National Reproductive Health Programme, through which efforts towards improvements in maternal health have been made.

Provision of a continuum of care during pregnancy, labour and delivery, and the postnatal period results in reduced maternal and neonatal morbidity and mortality. The 2014 KDHS collected information on the extent to which women in Kenya receive care during each of these stages by asking women age 15-49 who had a live birth in the five years preceding the survey questions about the antenatal, labour and delivery, and postnatal care they received. The findings can be used to identify populations underusing maternal health services and to assist in the planning of improvements in services.

9.1 ANTENATAL CARE

Antenatal care (ANC) from a skilled provider is important to monitor pregnancy and reduce the risk of morbidity for mother and baby during pregnancy and delivery. The quality of antenatal care can be monitored through the content of services received and the kind of information mothers are given during their visit. In the 2014 KDHS, women who gave birth in the five years preceding the survey were asked to

report on all persons they saw for antenatal care for their most recent birth. When a woman saw more than one provider, only the provider with the highest qualifications was considered in the tabulation of results.

Table 9.1 shows the percent distribution of women age 15-49 who had a live birth in the five years preceding the survey by source of antenatal care received during pregnancy, according to background characteristics. Ninety-six percent of women received antenatal care from a skilled provider (a doctor, a nurse, or a midwife) for their most recent birth in the five years preceding the survey. The majority of women (64 percent) received care from a nurse or midwife, while 31 percent received care from a doctor. Urban women (98 percent) were slightly more likely than rural women (94 percent) to receive antenatal care services from a skilled provider. In all regions except North Eastern (67 percent), 94 percent or more of women received antenatal care from a skilled provider. Receipt of antenatal care services from a skilled provider increased with increasing education and wealth. Eighty-nine percent of women in the lowest wealth quintile received antenatal care services from a skilled provider, compared with virtually all women (99 percent) in the highest wealth quintile.

Table 9.1 Antenatal care

Percent distribution of women age 15-49 who had a live birth in the five years preceding the survey by antenatal care (ANC) provider during pregnancy for the most recent birth and the percentage receiving antenatal care from a skilled provider for the most recent birth, according to background characteristics, Kenya 2014

Total	31.1	64.3	0.4	0.0	0.2	3.9	100.0	95.5	14,442

Note: If more than one source of ANC was mentioned, only the provider with the highest qualifications is considered in this tabulation.
[1] Skilled provider includes doctor, nurse, or midwife.

Table 9.1C shows the percent distribution of women age 15-49 who had a live birth in the five years preceding the survey by county and source of antenatal care. ANC from a skilled provider is virtually universal in Mombasa, Embu, Machakos, and Nandi (99 percent). Less than 90 percent of women in Garissa, Marsabit, West Pokot, and Samburu and less than 60 percent in Mandera and Wajir received ANC from a skilled provider; 47 percent of women in Mandera received no ANC at all.

Table 9.1C Antenatal care

Percent distribution of women age 15-49 who had a live birth in the five years preceding the survey by antenatal care (ANC) provider during pregnancy for the most recent birth and the percentage receiving antenatal care from a skilled provider for the most recent birth, according to county, Kenya 2014

[1] Skilled provider includes doctor, nurse, or midwife.

9.1.1 Number and Timing of Antenatal Visits

Regular antenatal care is helpful in identifying and preventing adverse pregnancy outcomes when it is sought early in the pregnancy and is continued until delivery. The World Health Organization recommends that women have at least four antenatal care visits during each pregnancy. It is possible

during these visits to detect health problems associated with a pregnancy and to plan interventions. In the event of any complications, more frequent visits are advised, and admission to a health facility may be necessary (MOH, 2012).

Table 9.2 presents the percent distribution of women age 15-49 who had a live birth in the five years preceding the survey by number of antenatal care (ANC) visits for the most recent live birth and by the timing of the first visit, according to residence and region. It also shows median number of months pregnant at first visit. Fifty-eight percent of pregnant women made four or more antenatal care visits during their pregnancy. This is an increase from 47 percent in the 2008-09 KDHS.

Table 9.2 Number of antenatal care visits and timing of first visit

Percent distribution of women age 15-49 who had a live birth in the five years preceding the survey by number of antenatal care (ANC) visits for the most recent live birth, and by the timing of the first visit, and among women with ANC, median months pregnant at first visit, according to residence and region, Kenya 2014

Note: Totals may not add up to 100 percent because women with missing information are not shown separately.

Urban women were more likely than rural women to have had four or more antenatal visits (68 percent and 51 percent, respectively). By region, the proportion of women having four or more ANC visits ranges from 37 percent in North Eastern to 73 percent in Nairobi.

Forty-three percent of women made their first antenatal care visit between the fourth and fifth months of pregnancy, and only 20 percent made their first visit before the fourth month of pregnancy. The median duration of pregnancy at the first antenatal care visit is 5.4 months. The timing of the first ANC visit is fairly consistent across regions.

9.1.2 Components of Antenatal Care

High-quality antenatal care operates on the principle that every pregnancy is at risk of complications. Therefore, apart from receiving basic care, every pregnant woman should be routinely monitored for complications. To assess the quality of antenatal care services, women who gave birth in the five years preceding the survey were asked a number of questions about the components of care they received when they were pregnant with their most recent live birth.

Table 9.3 presents information on the percentage of women age 15-49 with a live birth in the five years preceding the survey who took iron tablets, iron syrup, or iron and folic acid supplementation and intestinal parasite drugs during their most recent pregnancy in the five years preceding the survey. It also shows the percentage of women receiving antenatal care who were informed about the signs of pregnancy complications and who received specific routine services during ANC visits.

Table 9.3 Components of antenatal care

Among women age 15-49 with a live birth in the five years preceding the survey, the percentage who took iron tablets or syrup and drugs for intestinal parasites during the pregnancy of the most recent birth, and among women receiving antenatal care (ANC) for the most recent live birth in the five years preceding the survey, the percentage receiving specific antenatal services, according to background characteristics, Kenya 2014

	Among women with a live birth in the past five years, the percentage who during the pregnancy of their last birth:			Among women who received antenatal care for their most recent birth in the past five years, the percentage with selected services

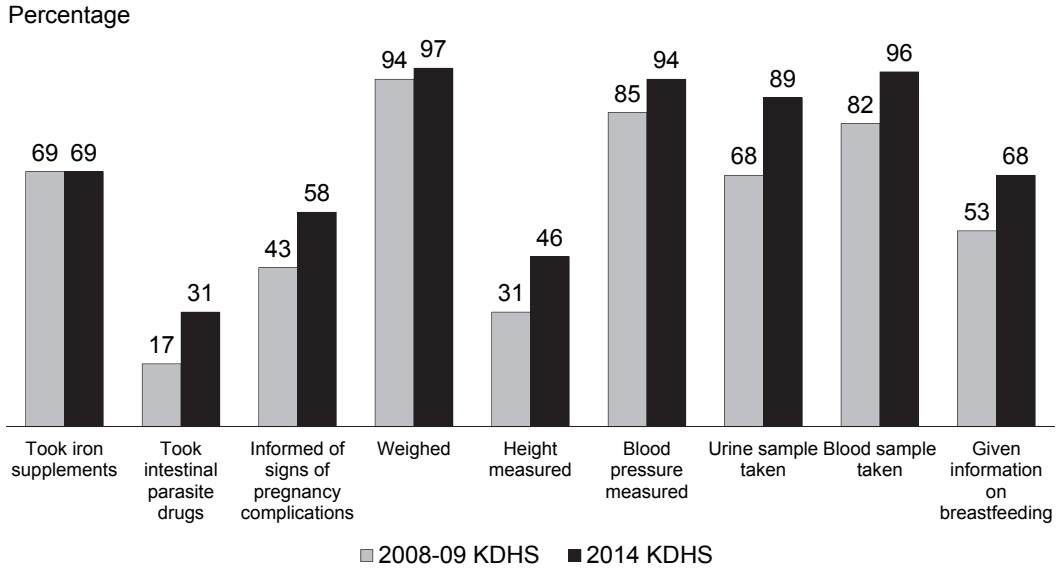
Sixty-nine percent of women with a live birth in the last five years took iron tablets, iron syrup, or iron and folic acid supplementation during the pregnancy of their most recent birth, and 31 percent took drugs for intestinal parasites. There are variations by background characteristics in intake of iron supplements and anti-parasite drugs. Iron supplements were most commonly taken by women age 20-34 (71 percent), while the proportion of women taking anti-parasite drugs increased with age. Women having a child of birth order six or higher (61 percent) were least likely to take iron supplements, but there was not much variation in use of anti-parasite drugs by birth order. While urban women were more likely to take iron supplements (75 percent) than rural women (66 percent), similar proportions of urban and rural women took anti-parasite drugs (32 percent and 31 percent, respectively). Regions with high proportions of women taking iron supplements (Nyanza, 83 percent; Coast, 82 percent; Nairobi, 75 percent) varied in the proportion of women taking anti-parasite drugs (Coast, 51 percent; Nyanza, 33 percent; Nairobi, 27 percent). Women with no education and women in the lowest wealth quintile were less likely to take either iron supplements or anti-parasite drugs than women with some education and those in wealthier households.

Use of various antenatal care services shows a general pattern according to which use is more common among women with births of lower order, women in urban areas, and women at higher levels of education and wealth. There are small variations in receipt of some of these services.

At least 9 in 10 women receiving ANC had their blood pressure measured (94 percent), had a blood sample taken (96 percent), and were weighed (97 percent); 89 percent had a urine sample taken. Lower proportions of women were given information on iron supplements (69 percent) and breastfeeding (68 percent), were informed of signs of pregnancy complications (58 percent), or had height measurements taken (46 percent). Women having a first birth (67 percent) and urban women (67 percent) were more likely than their counterparts to be informed about signs of pregnancy complications. Women in North Eastern (36 percent) were least likely to be informed about signs of complications. The proportion of women informed of signs of pregnancy complications increases with increasing education and wealth.

As shown in Figure 9.1, the proportion of women receiving all of the selected components of antenatal care except iron supplements, which has remained stable, has increased since the 2008-09 KDHS.

Figure 9.1 **Trends in components of antenatal care**



9.2 TETANUS TOXOID VACCINATION

Neonatal tetanus is a leading cause of death among infants in developing countries, where a considerable proportion of deliveries take place at home or at locations where hygienic conditions may be poor. Tetanus toxoid (TT) vaccine is given to women during pregnancy to prevent infant deaths caused by neonatal tetanus, which can occur when unclean tools are used to cut the umbilical cord after delivery. For full protection, women should receive at least two doses of TT vaccine during each pregnancy. If a woman has been vaccinated during a previous pregnancy or during maternal and neonatal tetanus vaccination campaigns, she may require only one dose for her current pregnancy. Five doses are considered to provide lifetime protection (Ministry of Health [MOH], 2012).

Table 9.4 presents the percentage of women age 15-49 with a live birth in the five years preceding the survey who received two or more TT injections during their last pregnancy and the percentage whose last live birth was protected against neonatal tetanus. More than half (51 percent) of pregnant women received two or more tetanus injections during their last pregnancy, and 76 percent had their last birth protected against neonatal tetanus. There has been a slight increase in the percentage of women whose last birth was protected against neonatal tetanus since the 2008-09 KDHS (73 percent).

Table 9.4 Tetanus toxoid injections

Among mothers age 15-49 with a live birth in the five years preceding the survey, the percentage receiving two or more tetanus toxoid injections during the pregnancy for the last live birth and the percentage whose last live birth was protected against neonatal tetanus, according to background characteristics, Kenya 2014

[1] Includes mothers with two injections during the pregnancy of her last birth, or two or more injections (the last within 3 years of the last live birth), or three or more injections (the last within 5 years of the last birth), or four or more injections (the last within 10 years of the last live birth), or five or more injections at any time prior to the last birth.

There are some differences in tetanus protection by region. More than 8 in 10 women in Coast and Nairobi (84 percent and 83 percent, respectively) had their last birth protected against neonatal tetanus, as compared with 6 in 10 women (60 percent) in North Eastern. Education and wealth have a positive association with receipt of two or more TT injections and protection of births against neonatal tetanus. Sixty-seven percent of births to women with no education were protected against neonatal tetanus, compared with 79 percent of births to women with a secondary or higher education. Similarly, women in the lowest wealth quintile (70 percent) were less likely than women in the highest quintile (81 percent) to have their last birth protected against neonatal tetanus.

9.3 PLACE OF DELIVERY

Increasing the percentage of births delivered in health facilities is important for reducing deaths arising from complications of pregnancy. The expectation is that if complications arise during delivery in a health facility, a skilled birth attendant can manage them or refer the mother to the next level of care. Kenya is promoting skilled care during pregnancy and childbirth for both mothers and newborns (MOH, 2009).

Table 9.5 presents the percent distribution of live births in the five years preceding the survey by place of delivery and the percentage of births delivered in a health facility, according to background characteristics. More than one-third of births (37 percent) took place at home. Sixty-one percent of births were delivered in a health facility: 46 percent in a public-sector facility and 15 percent in a private-sector facility. This is a large increase in facility deliveries from 43 percent in 2008-09.

Table 9.5 Place of delivery

Percent distribution of live births in the five years preceding the survey by place of delivery and percentage delivered in a health facility, according to background characteristics, Kenya 2014

Total	46.0	15.2	37.4	1.0	0.5	100.0	61.2	19,564

Note: Total includes 51 births for whom information on ANC visits is missing.
[1] Includes only the most recent birth in the five years preceding the survey

By age, delivery in a health facility is least common among births to mothers age 35-49 (53 percent), and it decreases as birth order increases. Delivery in a health facility increases with the number of ANC visits the mother made. Children in urban areas (82 percent) are much more likely to be delivered in a health facility than rural children (50 percent). The percentage of births delivered in a health facility ranges from 29 percent in North Eastern region to 90 percent in Central.

Health facility delivery increases with increasing mother's education and wealth. For example, 25 percent of births to mothers with no education are delivered in a health facility, as compared with 84 percent of births to mothers with a secondary or higher education. Similarly, 30 percent of births to mothers in the lowest wealth quintile are delivered in a health facility, compared with 93 percent of births to mothers in the highest quintile. Private-sector deliveries are more common among births to women in the higher wealth quintiles and women at higher educational levels.

Table 9.5C shows the county-level percent distribution of live births in the five years preceding the survey by place of delivery and the percentage of births delivered in a health facility. The proportion of health facility deliveries ranges from 18 percent in Wajir to 93 percent each in Kiambu and Kirinyaga.

9.4 ASSISTANCE DURING DELIVERY

Obstetric care from a health professional during delivery is recognised as critical in reducing maternal and neonatal mortality. Table 9.6 shows the percent distribution of live births in the five years preceding the survey by person providing assistance during delivery, the percentage of births assisted by a skilled provider, and the percentage of births delivered via caesarean section, according to background

characteristics. Sixty-two percent of births were assisted at delivery by a skilled birth attendant (doctor, nurse, or midwife), 13 percent were assisted by relatives or friends, and 19 percent were assisted by a traditional birth attendant. Five percent of births were unassisted. The role of community health workers in delivery assistance is very limited (less than 1 percent). Almost all health facility births (99 percent) were assisted by a skilled provider, as compared with just 3 percent of births delivered outside of health facilities.

Table 9.6 Assistance during delivery

Percent distribution of live births in the five years preceding the survey by person providing assistance during delivery, percentage of birth assisted by a skilled provider and percentage delivered by caesarean-section, according to background characteristics, Kenya 2014

Note: If the respondent mentioned more than one person attending during delivery, only the most qualified person is considered in this tabulation. Total includes 51 births for whom information on ANC visits is missing and 114 births for whom place of delivery is missing.
[1] Skilled provider includes doctor, nurse, or midwife.
[2] Includes only the most recent birth in the five years preceding the survey

The percentage of births assisted by a skilled birth attendant has increased in the last five years, from 44 percent in 2008-09 to 62 percent in 2014. It is noteworthy that delivery assistance by a skilled birth attendant in rural areas has increased from 37 percent to 50 percent.

Nine percent of births are delivered via caesarean section. The likelihood of this type of delivery increases with mother's age, decreases with birth order, and increases with the number of ANC visits the mother made. Births in urban areas (15 percent) are more likely to be delivered via caesarean section. The likelihood of caesarean-section deliveries increases with increasing mother's education and wealth.

Caesarean deliveries are noticeably more common in Nairobi and among babies born to women in the highest wealth quintile; about one in five of these births occurs via caesarean-section.

Table 9.6C shows the county-level percent distribution of live births in the five years preceding the survey by person providing assistance during delivery, the percentage of births assisted by a skilled provider, and the percentage delivered via caesarean section. The proportion of births assisted by a skilled provider ranges from 22 percent in Wajir to 93 percent in Kiambu. Caesarean-section deliveries are least common in Turkana and Wajir (1 percent). In five counties, caesarean deliveries exceed 15 percent: Kirinyaga, Embu, Tharaka-Nithi, Kiambu, and Nairobi.

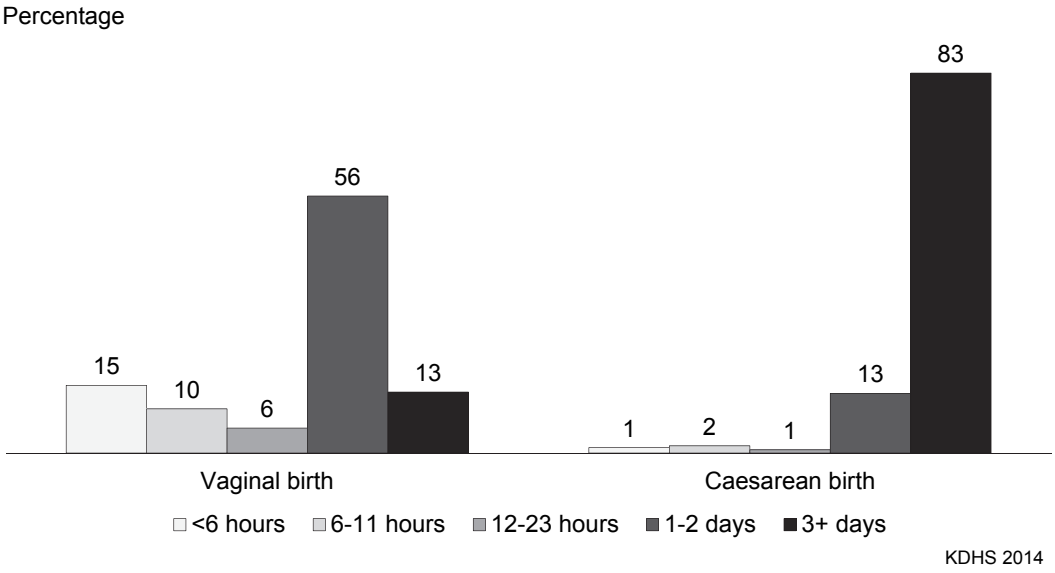
Note: If the respondent mentioned more than one person attending during delivery, only the most qualified person is considered in this tabulation.
[1] Skilled provider includes doctor, nurse, or midwife.

Figure 9.2 shows the percent distribution of mothers with a birth in the five years preceding the survey who delivered their last birth in a health facility, by duration of stay in the facility and type of delivery. The majority of women with a vaginal birth stayed at a health facility for two days or fewer (87 percent). In contrast, the majority of women who delivered via caesarean section (83 percent) stayed at a health facility for three or more days.

Figure 9.2 **Mother's duration of stay in the health facility after giving birth**



9.5 POSTNATAL CARE

The postpartum period is particularly important for women, since during this period they may develop serious, life-threatening complications. Evidence has shown that a large proportion of deaths occur during the postpartum period, with postpartum haemorrhage being a major cause (UNDP, WHO, UNFPA, World Bank, 2006). A postnatal care visit is an ideal time to educate a new mother on how to care for herself and her newborn. The 2014 KDHS asked women age 15-49 who had a live birth in the two years preceding the survey about what postnatal care they and their newborn received, including timing and provider.

9.5.1 Timing of First Postnatal Checkup for the Mother

Table 9.7 presents, among women age 15-49 giving birth in the two years before the survey, the percent distribution of mothers' first postnatal checkup for their last live birth by time after delivery and the percentage of women who received a postnatal checkup in the first two days after giving birth, according to background characteristics. Fifty-three percent of women received postnatal care within the critical two-day period following delivery. Thirty-eight percent of women received postnatal care within four hours after delivery, 9 percent received care within 4-23 hours, and 6 percent were seen 1-2 days following delivery. Overall, 43 percent of women did not receive a postnatal checkup within the first six weeks after delivery. In the North Eastern region, 80 percent of women did not have any postnatal care.

Table 9.7 Timing of first postnatal checkup for the mother

Among women age 15-49 giving birth in the two years preceding the survey, the percent distribution of the mother's first postnatal checkup for the last live birth by time after delivery, and the percentage of women with a live birth in the two years preceding the survey who received a postnatal checkup in the first two days after giving birth, according to background characteristics, Kenya 2014

Background characteristic	Time after delivery of mother's first postnatal checkup								Percentage of women with a postnatal checkup in the first two days after birth	Number of women

Note: Total includes six women for whom information on place of delivery is missing.
[1] Includes women who received a checkup after 41 days

9.5.2 Provider of First Postnatal Checkup for the Mother

The skill level of the person who provides the first postnatal checkup has important implications for maternal and neonatal health. Table 9.8 shows, among women age 15-49 giving birth in the two years preceding the survey, the percent distribution by type of provider of the mother's first postnatal health check in the two days after the last live birth, according to background characteristics. Just under half (49 percent) of women received postnatal care from a doctor, a nurse, or a midwife, an increase of 12 percentage points from the 2008-09 KDHS (37 percent). At the same time, the role of traditional birth attendants in providing postnatal checks declined from 10 percent in 2008-09 to 4 percent in 2014.

Postnatal care from a skilled provider is highest among women younger than age 35 (50 percent), first-order births (64 percent), mothers who delivered in a health facility (72 percent), and mothers in urban areas (66 percent). Across regions, postnatal care from a skilled birth attendant is highest in Central (72 percent) and Nairobi (71 percent) and lowest in North Eastern (14 percent). Skilled postnatal care increases with increasing education and wealth, from 16 percent of women with no education and 25 percent of women in the lowest wealth quintile to 68 percent of women with a secondary or higher education and 74 percent of women in the highest wealth quintile.

Table 9.8 Type of provider of first postnatal checkup for the mother

Among women age 15-49 giving birth in the two years preceding the survey, the percent distribution by type of provider of the mother's first postnatal health check in the two days after the last live birth, according to background characteristics, Kenya 2014

Note: Total includes six women for whom information on place of delivery is missing.

9.5.3 Timing of First Postnatal Checkup for the Newborn

Newborn care is essential to reduce neonatal health problems and death. To identify, manage, and prevent newborn health complications, the government of Kenya recommends at least three postnatal checkups for the newborn within the seven days after delivery, which is considered a critical time period for neonates and mothers (MOH, 2012).

Table 9.9 shows the percent distribution of last births in the two years preceding the survey by timing of the first postnatal checkup, along with the percentage of births with a postnatal checkup in the first two days after birth, according to background characteristics.

Thirty-six percent of newborns had a postnatal checkup within the critical first two days after birth. The majority of newborns (62 percent) did not receive a postnatal checkup in the first week after birth. Although the patterns seen above for mothers' postnatal care are largely repeated for newborns' postnatal care, it is noteworthy that more than half of infants born in a health facility (52 percent) did not receive postnatal checkups.

Table 9.9 Timing of first postnatal checkup for the newborn

Percent distribution of last births in the two years preceding the survey by time after birth of first postnatal checkup, and the percentage of births with a postnatal checkup in the first two days after birth, according to background characteristics, Kenya 2014

Note: Total includes six births for whom information on place of delivery is missing.
[1] Includes newborns who received a checkup after the first week

9.5.4 Provider of First Postnatal Checkup for the Newborn

Table 9.10 presents the percent distribution of last births in the two years preceding the survey by type of provider of newborn care during the first two days after delivery, according to background characteristics. Thirty-three percent of newborns received postnatal care in the two days following birth from a doctor, nurse, or midwife, and 2 percent received care from a traditional birth attendant. As is the case with postnatal care for mothers, practically no newborns received postnatal care from a community health worker. Patterns of postnatal care for newborns by background characteristics are similar to the patterns observed for their mothers.

Table 9.10 Type of provider of first postnatal checkup for the newborn

Percent distribution of last births in the two years preceding the survey by type of provider of the newborn's first postnatal health check during the two days after the last live birth, according to background characteristics, Kenya 2014

9.6 PROBLEMS IN ACCESSING HEALTH CARE

Many factors can prevent women from getting medical advice or treatment for themselves when they are sick. Information on such factors is particularly important in understanding and addressing the barriers women may face in seeking care during pregnancy and labour.

In the 2014 KDHS, women age 15-49 were asked whether or not each of the following factors would be a significant problem for them in seeking medical care: getting permission to go for treatment, getting money for treatment, distance to a health facility, and not wanting to go alone. Table 9.11 presents the percentage of women who reported that they have serious problems accessing health care for themselves when they are sick, according to type of problem and background characteristics. The most often cited problem is getting money to go for treatment (37 percent), followed by distance to the health facility (23 percent). Eleven percent of women cited not wanting to go alone as a problem, and 6 percent reported that getting permission to go for treatment was a problem. Overall, 46 percent of women reported that at least one of these problems would pose a barrier to seeking health care for themselves when they are sick.

Table 9.11 Problems in accessing health care

Percentage of women age 15-49 who reported that they have serious problems in accessing health care for themselves when they are sick, by type of problem, according to background characteristics, Kenya 2014

Background characteristic	Problems in accessing health care					
	Getting permission to go for treatment	Getting money for treatment	Distance to health facility	Not wanting to go alone	At least one problem accessing health care	Number of women

Middle	5.8	42.0	25.0	10.9	52.8	2,859
Fourth	4.5	29.7	17.1	8.1	39.6	3,113
Highest	2.9	16.8	7.7	6.1	23.6	3,827
Total	6.0	36.7	22.7	10.6	46.1	14,625

Note: Total includes 11 women for whom information on employment in the last 12 months is missing.

Younger women, women with fewer children, and women who have never been married are less likely than other women to report having any of these four problems in accessing health care. Women who are employed but not for cash are more likely to report at least one problem than women who are either unemployed or employed for cash. Although getting permission is not widely observed as a problem at the national level, 27 percent of women in the North Eastern region cited this problem as a barrier to accessing care.

9.7 FISTULA

The 2014 KDHS included a series of questions on fistula, a condition that may develop during prolonged or obstructed labour when the blood supply to the tissues of the vagina, bladder, and/or rectum is cut off, resulting in the formation of an opening through which urine and/or faeces pass uncontrollably. Women who develop fistulas are often socially rejected and face a number of related health concerns. All

women were asked whether they had heard of fistula and, if they had, whether they themselves had experienced fistula-like symptoms. Results are presented in Table 9.12 by background characteristics.

Slightly over half (54 percent) of women have heard of fistula. Urban women are more likely (63 percent) than rural women (48 percent) to have heard of fistula. Awareness of fistula is higher among women in Nairobi (70 percent) and awareness increases with increasing wealth and education. One percent of women have experienced fistula-like symptoms. Because of the low percentage of women who have experienced symptoms indicative of fistula, any variations by background characteristics should be considered with caution.

CHILD HEALTH 10

Andolo Miheso, Lucy Gathigi Maina, Annah W. Wamae

Key Findings

- The percentage of all births with a reported birth weight has increased in the last five years from 47 percent to 66 percent.
- Seventy-nine percent of children age 12-23 months have received all basic vaccines, slightly higher than the 77 percent observed in the 2008-09 KDHS.
- Nine percent of children under age 5 showed symptoms of acute respiratory infection in the two weeks before the survey; 66 percent of these children were taken to a health facility or provider for advice or treatment.
- Twenty-four percent of children under age 5 had a fever in the two weeks before the survey; 63 percent of these children were taken to a health facility or provider for advice or treatment.
- Fifteen percent of children under age 5 had diarrhoea in the two weeks before the survey.
- The proportion of children with diarrhoea taken to a health provider for advice or treatment increased from 49 percent in the 2008-09 KDHS to 58 percent in the 2014 KDHS.
- The proportion of children with diarrhoea given fluid from ORS packets has increased over the past five years, from 39 percent in 2008-09 to 54 percent in 2014.
- The percentage of women who know that ORS can be used to treat diarrhoea in children has increased from 78 percent in 2008-09 to 93 percent in 2014.
- The percentage of children whose stools are disposed of safely has increased from 78 percent in 2008-09 to 83 percent in 2014.

The Division of Family Health in the Ministry of Health is supporting several child survival interventions, including various operational initiatives, to improve the health of children in Kenya. These include the Expanded Programme on Immunisation, the Integrated Management of Childhood Illnesses Initiative, the Community-Based Newborn Care Programme, the Infant and Young Child Feeding Programme, a micronutrient supplementation programme, and a vitamin A and deworming campaign. Biannual child-mother health and nutrition weeks, called 'Malezi Bora' in Kiswahili, also are held in May and November to deliver a specific package of health interventions targeting mothers and children under age 5. The ultimate goal of the 'Malezi Bora' strategy is to improve delivery of routine health and nutrition services targeting children, expectant women, and lactating mothers.

This chapter reviews information from the 2014 KDHS that is useful in managing the Ministry of Health's child health and survival programmes. Specifically, the chapter presents findings on infant birth weight and size at birth, childhood vaccination coverage, and treatment practices and contact with health services when a child is ill with respiratory infection, diarrhoea, and fever.

10.1 CHILD'S WEIGHT AND SIZE AT BIRTH

A child's birth weight or size at birth is an important indicator of the child's vulnerability to the risk of childhood illnesses and chances of survival. For births in the five years preceding the 2014 KDHS, birth weight was recorded in the questionnaire if available from the Mother and Child Health Booklet, some other written record, or the mother's recall. Since birth weight may not be known for many babies, the mother's estimate of the baby's size at birth was also obtained. Such estimates, even though subjective, can be a useful proxy for the weight of the child at birth. Children reported to be "very small" or "smaller than average" at birth or children whose birth weight was less than 2.5 kilograms are considered to have a higher than average risk of early childhood death.

Table 10.1 presents information on size and weight at birth for children born in the five years prior to the 2014 KDHS according to background characteristics. Based on the mother's assessment, 3 percent of children were very small at birth, 12 percent were smaller than average, and 84 percent were average or larger in size. Children were most likely to be reported by their mothers as very small or smaller than average in the North Eastern region (25 percent) and least likely in Nyanza (8 percent). Twenty percent of children born to mothers with no education were considered by the mother to be very small or smaller than average, as compared with 14 percent of children born to mothers who had a secondary or higher education.

Table 10.1 Child's size and weight at birth

Percent distribution of live births in the five years preceding the survey by mother's estimate of baby's size at birth, percentage of live births in the five years preceding the survey that have a reported birth weight, and among live births in the five years preceding the survey with a reported birth weight, percentage less than 2.5 kg, according to background characteristics, Kenya 2014

Note: Total includes one birth for whom information on mother's smoking status is missing. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] Based on either a written record or the mother's recall

Table 10.1 shows that birth weights were reported for 66 percent of children born in the five years before the survey. This represents an improvement from the 47 percent of children for whom birth weights were obtained in the 2008-09 KDHS. The increased availability of birth weight data is not surprising since the proportion of births occurring in health facilities increased between the two surveys (see Chapter 9), and children are more likely to be weighed at birth when delivered in an institutional setting. The variation in the proportion of children for whom a birth weight was obtained in the KDHS in fact closely parallels differences in the proportions of births delivered in health facilities.

Among children born in the five years before the survey with a reported birth weight, 8 percent were of low birth weight (less than 2.5 kg). The percentage of low birth weight children varied from a high of 13 percent in the Coast region to a low of 4 percent in the Nyanza region. Differences by other background characteristics are generally small.

10.2 VACCINATION COVERAGE

Universal immunisation of children against six common vaccine-preventable diseases, namely tuberculosis, diphtheria, whooping cough (pertussis), tetanus, polio, and measles, is crucial to reducing infant and child mortality. Other childhood vaccines given in Kenya protect against hepatitis B and *Haemophilus influenzae* type b (Hib). The pneumococcal vaccine introduced into Kenya's routine immunisation programme in February 2012 protects against *Streptococcus pneumoniae* bacteria, which cause severe pneumonia, meningitis, and other illnesses. The 2014 KDHS collected information on the coverage of all of these vaccines among children born in the five years preceding the survey. The information obtained in the survey on differences in vaccination coverage among subgroups of children is useful for programme planning and targeting resources towards areas most in need.

According to the guidelines developed by the World Health Organization, children are considered to have received all basic vaccinations when they have received a vaccination against tuberculosis (also known as BCG), three doses each of the DPT-HepB-Hib (also called pentavalent) and polio vaccines, and a vaccination against measles. The BCG vaccine is usually given at birth or at first clinical contact, while the DPT-HepB-Hib and polio vaccines are given at approximately age 6, 10, and 14 weeks. Measles vaccinations should be given at or soon after age 9 months. The Kenyan immunisation programme considers a child to be fully vaccinated if the child has received all basic vaccinations and three doses of the pneumococcal vaccine (also given at age 6, 10, and 14 weeks).

Information on vaccination coverage was obtained in two ways in the 2014 KDHS: from written vaccination records, including the Mother and Child Health Booklet and other health cards, and from mothers' verbal reports. The Ministry of Health introduced the Mother and Child Health Booklet in 2010 to replace the various cards used to record services offered in maternal and child health clinics, maternity wards, and family planning clinics. In the KDHS, for each child born in the five years before the survey, mothers were asked to show the interviewer the Mother and Child Health Booklet or health card used for recording the child's immunisations. If the Mother and Child Health Booklet or the card was available, the interviewer copied the dates of each vaccination received. If a vaccination was not recorded in the Mother and Child Health Booklet or on the card as being given, the mother was asked to recall whether that particular vaccination had been given. If the mother was not able to present the Mother and Child Health Booklet or card for a child, she was asked to recall whether the child had received BCG, polio, DPT-HepB-Hib, measles, and pneumococcal vaccine. If she indicated that the child had received the polio, DPT-HepB-Hib, or pneumococcal vaccine, she was asked the number of doses that the child received.

Table 10.2 presents data on vaccination coverage among children age 12-23 months by source of information (i.e., vaccination record or mother's report). Children age 12-23 months are the youngest cohort who have reached the age by which a child should be fully immunised.

Table 10.2 Vaccinations by source of information

Percentage of children age 12-23 months who received specific vaccines at any time before the survey, by source of information (vaccination card or mother's report), and percentage vaccinated by 12 months of age, Kenya 2014

Source of information	BCG	DPT-HepB-Hib[1] 1	DPT-HepB-Hib[1] 2	DPT-HepB-Hib[1] 3	Polio[2] 0	Polio[2] 1	Polio[2] 2	Polio[2] 3	Measles	All basic vacci-nations[3]	Pneumococcal 1	Pneumococcal 2	Pneumococcal 3	Fully vacci-nated[4]	No vacci-nations	Number of children
Vaccinated at any time before survey

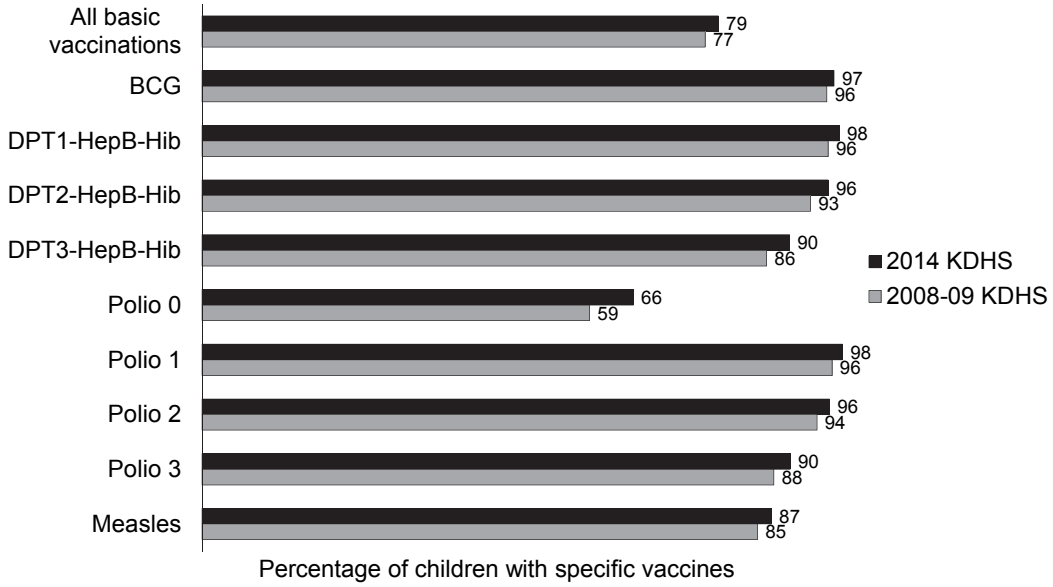
Mother's report	23.5	23.3	22.4	18.9	8.8	23.6	22.3	18.8	21.7	16.3	22.5	21.1	18.0	15.2	1.6	957
Either source	96.7	97.5	95.8	89.9	66.2	98.0	96.1	90.0	87.1	79.4	93.7	90.8	85.1	74.9	1.6	3,777
Vaccinated by 12 months of age[5]	95.9	97.0	94.9	88.3	66.1	97.5	94.9	88.1	78.9	71.3	93.0	90.0	83.2	67.2	2.0	3,777

[1] DPT-HepB-Hib is also called pentavalent.
[2] Polio 0 is the polio vaccination given at birth. The data on polio vaccination were adjusted for a likely misinterpretation of polio 0 and polio 1; for children whose mothers reported that they received three doses of DPT-HepB-Hib and polio 0, polio 1, and polio 2, it was assumed that polio 0 was in fact polio 1, polio 1 was polio 2 and polio 2 was polio 3.
[3] BCG, measles, and three doses each of DPT-HepB-Hib and polio vaccine (excluding polio vaccine given at birth)
[4] BCG, measles, and three doses each of DPT-HepB-Hib, polio (excluding polio vaccine given at birth), and pneumococcal vaccine
[5] For children whose information is based on the mother's report, the proportion of vaccinations given during the first year of life is assumed to be the same as for children with a written record of vaccination.

Table 10.2 and Figure 10.1 show that 79 percent of children age 12-23 months received all basic vaccinations, and 75 percent are fully vaccinated. Only 2 percent of children had not received any vaccinations. Ninety-seven percent of children received the BCG vaccination, 98 percent the first dose of DPT-HepB-Hib, 98 percent the first dose of polio, and 94 percent the first dose of the pneumococcal vaccine. Eighty-seven percent of children have received a measles vaccination. Coverage rates decline for subsequent doses, with 90 percent of children receiving the recommended three doses of DPT-HepB-Hib, 90 percent the three doses of polio, and 85 percent the three doses of the pneumococcal vaccine. Dropout rates, which represent the proportion of children who receive the first dose of a vaccine but do not go on to get the third dose, were around 8 percent for both polio and DPT-HepB-Hib and 9 percent for the pneumococcal vaccine.

Figure 10.1 **Trends in vaccination coverage among children age 12-23 months***



* Refers to vaccinations received at any time before the survey

Table 10.3 presents vaccination coverage (according to card information and mothers' reports) among children age 12-23 months by background characteristics. Vaccination records were available for 75 percent of these children. For the remaining children, information on vaccinations is based solely on the mother's report. There is no difference in the coverage rates between male and female children. Immunisation coverage decreases as birth order increases, with 80 percent of first-born children and only 59 percent of children of birth order six and above being fully immunised. Immunisation coverage increases with increasing mother's education; more than three-quarters of children whose mothers have completed primary or higher education are fully immunised, as compared with 55 percent of children whose mothers have no education. Only 62 percent of children in the lowest wealth quintile are fully immunised, compared with around 8 in 10 children in the other quintiles.

Coverage is highest in the Central (90 percent) region and lowest in the North Eastern region, where only 51 percent of children are fully immunised. Eleven percent of children in North Eastern have not received any of the recommended immunisations, as compared with 2 percent or less in the other regions.

Table 10.3 Vaccinations by background characteristics

Percentage of children age 12-23 months who received specific vaccines at any time before the survey (according to a vaccination card or the mother's report), and percentage with a vaccination card, by background characteristics, Kenya 2014

[1] DPT-HepB-Hib is also called pentavalent.
[2] Polio 0 is the polio vaccination given at birth. The data on polio vaccination were adjusted for a likely misinterpretation of polio 0 and polio 1; for children whose mothers reported that they received three doses of DPT-HepB-Hib and polio 0, polio 1, and polio 2, it was assumed that polio 0 was in fact polio 1, polio 1 was polio 2 and polio 2 was polio 3.
[3] BCG, measles, and three doses each of DPT-HepB-Hib and polio vaccine (excluding polio vaccine given at birth)
[4] BCG, measles, and three doses each of DPT-HepB-Hib, polio (excluding polio vaccine given at birth), and pneumococcal vaccine

Differentials in immunisation coverage across counties are presented in Table 10.3C. The proportion of children who are fully immunised is 90 percent or higher in Machakos, Nyamira, Vihiga, Tharaka-Nithi, Nandi, and Kiambu. Less than half of children are fully immunised in Wajir and Mandera, and only 31 percent are fully immunised in West Pokot.

Table 10.3C Vaccinations by county

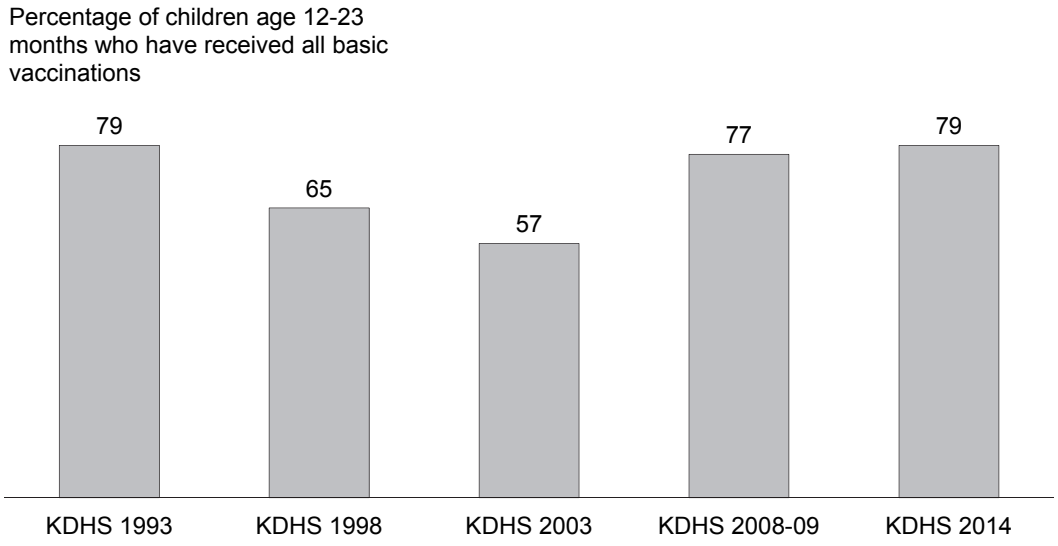
Note: Figures in parentheses are based on 25-49 unweighted cases.
[1] DPT-HepB-Hib is also called pentavalent.
[2] Polio 0 is the polio vaccination given at birth. The data on polio vaccination were adjusted for a likely misinterpretation of polio 0 and polio 1; for children whose mothers reported that they received three doses of DPT-HepB-Hib and polio 0, polio 1, and polio 2, it was assumed that polio 0 was in fact polio 1, polio 1 was polio 2 and polio 2 was polio 3.
[3] BCG, measles, and three doses each of DPT-HepB-Hib and polio vaccine (excluding polio vaccine given at birth)
[4] BCG, measles, and three doses each of DPT-HepB-Hib, polio (excluding polio vaccine given at birth), and pneumococcal vaccine

Figure 10.2 compares the results of the 2014 KDHS with immunisation data from the KDHS surveys carried out between 1993 and 2008-09 in order to explore the trends in childhood vaccination coverage over the past 20 years in Kenya. Because the pneumococcal vaccine was introduced only in 2012, Figure 10.2 focuses on changes in the proportion of children receiving all basic immunisations, that is, a BCG vaccination, three doses each of the DPT-HepB-Hib and polio vaccines, and a vaccination against measles. Some caution should be exercised in interpreting the trends in Figure 10.2 since some areas in northern Kenya were not included in the 1993 and 1998 surveys, and there are minor differences in the method used for calculating the polio immunisation rate.

Figure 10.2 shows that the proportion of children age 12-23 months who received all basic immunisations declined from 79 percent in 1993 to 65 percent in 1998 and then dropped again to a low of 57 percent in 2003. By 2008-09, the rate had rebounded to 77 percent. Between 2008-09 and 2014, however, the rate increased slightly to 79 percent.

Figure 10.2 **Trends in childhood vaccination coverage**



* Data from 2003 and later are nationally representative, while data before 2003 exclude North Eastern region and several northern districts in the Eastern and Rift Valley regions.

10.3 ACUTE RESPIRATORY INFECTION

Acute respiratory infection (ARI) is a leading cause of childhood morbidity and mortality throughout the world. Early diagnosis and treatment with antibiotics can reduce the number of deaths caused by ARI. In the 2014 KDHS, the prevalence of ARI symptoms was estimated by asking mothers whether, in the two weeks preceding the survey, their children under age 5 had been ill with a cough accompanied by short, rapid breathing and difficulty breathing as a result of a problem in the chest. These symptoms are consistent with pneumonia. It should be noted that the data collected on ARI symptoms are subjective because they are based on a mother's perception of the illness without validation by medical personnel.

Table 10.4 shows that 9 percent of children under age 5 were ill with symptoms of an acute respiratory infection in the two weeks before the survey. Differences in the prevalence of ARI symptoms by background characteristics are generally minor, with the largest differentials observed by age and region. Considering the age pattern, the proportion of children reported to have ARI symptoms was lowest among those less than age 6 months (4 percent) and peaked among those age 6-11 months (11 percent). With regard to regional differences, the highest prevalence of ARI symptoms was reported among children in the Western region (13 percent) and the lowest among children in the North Eastern region (4 percent).

Table 10.4 Prevalence and treatment of symptoms of ARI

Among children under age five, the percentage who had symptoms of acute respiratory infection (ARI) in the two weeks preceding the survey and among children with symptoms of ARI, the percentage for whom advice or treatment was sought from a health facility or provider and the percentage who received antibiotics as treatment, according to background characteristics, Kenya 2014

Highest	6.1	3,782	73.5	59.3	231
Total	8.5	18,702	65.7	53.1	1,582

Note: Total includes one child for whom information on mother's smoking status is missing and five children for whom information on cooking fuel in the household is missing. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] Symptoms of ARI, considered a proxy for pneumonia, include cough accompanied by short, rapid breathing which was chest-related and/or by difficult breathing which was chest-related.
[2] Excludes pharmacy, shop, and traditional practitioner
[3] Includes grass, shrubs, crop residues

Mothers who reported that their child had ARI symptoms were asked about the actions they had taken to treat the illness. Table 10.4 shows that, among children with ARI symptoms, two-thirds were taken to a health facility or health provider for advice or treatment. This is an increase from the 2008-09 KDHS, when treatment or advice was sought from a health provider for 56 percent of children ill with ARI symptoms. Also, antibiotics were used to treat children with ARI symptoms somewhat more often in 2014 than in 2008-09 (53 percent and 50 percent, respectively).

As Table 10.4 shows, the treatment that children ill with ARI symptoms received differed across subgroups. The proportion of children with ARI symptoms for whom medical treatment or advice was sought and the proportion receiving antibiotics generally decrease with child's age and increase with increasing mother's education and wealth. The greatest variations in treatment patterns were by region. The proportion of children with ARI symptoms for whom treatment or advice was sought from a health provider ranged from only 35 percent in North Eastern to 71 percent in Nyanza. The proportion of children with ARI symptoms who were treated with antibiotics was lowest in North Eastern (34 percent) and highest in Rift Valley (62 percent).

Differentials in ARI prevalence across counties are presented in Table 10.4C. The counties with the highest proportion of children reported as ill with ARI symptoms included Vihiga (17 percent), Bungoma (16 percent), Baringo (14 percent), Homa Bay (13 percent), and Migori (13 percent), while ARI prevalence was lowest in Mandera (2 percent) and in Turkana, Garissa, Kisumu, Kirinyaga, and Nyamira (each 3 percent). Due to the small numbers of children with ARI symptoms in most counties, it is not possible to compare treatment patterns across counties.

Table 10.4C Prevalence of symptoms of ARI

[1] Symptoms of ARI, considered a proxy for pneumonia, include cough accompanied by short, rapid breathing which was chest-related and/or by difficult breathing which was chest-related.

10.4 FEVER

Fever is a major symptom of malaria and other acute infections in children. In the 2014 KDHS, mothers were asked whether their children under age 5 had a fever in the two weeks preceding the survey and, if so, whether any treatment was sought. Table 10.5 shows the percentage of children under age 5 with a fever during the two weeks preceding the survey and the percentage receiving antimalarial drugs and antibiotics, by background characteristics.

Twenty-four percent of children under age 5 had a fever in the two weeks preceding the survey. Fever was least common among children under age 6 months (17 percent) and most common among children age 6-23 months (30-31 percent). The prevalence of fever was highest in Nyanza (37 percent), Western (36 percent), and Coast (27 percent) and lowest in North Eastern (9 percent).

Advice or treatment was obtained from a health provider for 63 percent of children with a fever. This represents an increase from the 49 percent reported in 2008-09. The proportion of children for whom advice or treatment was sought from a health provider was lowest in the North Eastern and Western regions (50 percent and 52 percent, respectively). The likelihood that a child ill with fever received care or treatment generally increased with increasing mother's education and wealth.

Just over one-quarter of children with a fever received antimalarial drugs. Additional information on the use of antimalarial drugs to treat fever in children is provided in Chapter 12, which presents data

from the KDHS relating to efforts to prevent and treat malaria. Slightly more than 4 in 10 children with a fever were given antibiotics. Antibiotics were given most often to children age 6-23 months; urban children; children from the Central, Rift Valley, and Eastern regions; children whose mothers had completed primary or higher education; and children in the two highest wealth quintiles.

Table 10.5 Prevalence and treatment of fever

Among children under age five, the percentage who had a fever in the two weeks preceding the survey; and among children with fever, the percentage for whom advice or treatment was sought from a health facility or provider, the percentage who took antimalarial drugs, and the percentage who received antibiotics as treatment, by background characteristics, Kenya 2014

Total	24.4	18,702	62.5	27.0	43.2	4,562

[1] Excludes pharmacy, shop, market, and traditional practitioner

As Table 10.5C shows, the prevalence of fever varied greatly across counties, from a high of 49 percent in Vihiga to a low of 5 percent in Mandera. Children with a fever were most likely to be taken to a health facility or provider for advice or treatment in West Pokot (77 percent) and least likely in Kakamega (42 percent). Children with a fever were most likely to have received antibiotics in Elgeyo Marakwet (73 percent).

Table 10.5C Prevalence and treatment of fever

Among children under age five, the percentage who had a fever in the two weeks preceding the survey; and among children with fever, the percentage for whom advice or treatment was sought from a health facility or provider, the percentage who took antimalarial drugs, and the percentage who received antibiotics as treatment, by county, Kenya 2014

10.5 DIARRHOEAL DISEASE

Dehydration caused by severe diarrhoea is a major cause of morbidity and mortality among young children, although the condition can be easily treated with oral rehydration therapy (ORT). Exposure to diarrhoea-causing agents is frequently related to the use of contaminated water and to unhygienic practices in food preparation and disposal of excreta. Reducing deaths from diarrhoea largely depends on whether the children are able to access lifesaving oral rehydration salts (ORS) and zinc tablets.

In the 2014 KDHS, mothers of children born during the five years preceding the survey were asked a series of questions about episodes of diarrhoea suffered by their children in the two weeks before the survey, including questions on feeding practices during diarrhoea, treatment of the condition, and their knowledge and use of ORS.

Table 10.6 shows the percentage of children under age 5 who had diarrhoea in the two weeks preceding the survey, by background characteristics. Overall, 15 percent of children under age 5 had diarrhoea, with 2 percent having diarrhoea with blood. Diarrhoea prevalence is highest among children age 6-11 and 12-23 months (27 percent and 24 percent, respectively). Diarrhoea is less common among children who used improved, private toilet facilities (11 percent) than among those who use non-improved or shared improved facilities (16 percent each). The Western, Nyanza, and Coast regions have the highest prevalence of diarrhoea (18-20 percent), and North Eastern has the lowest (8 percent).

Table 10.6C presents differences in diarrhoea prevalence by county. The proportion of children reported to have had diarrhoea was highest in Migori (28 percent), Homa Bay (24 percent), and Vihiga (24 percent). The lowest proportions of children with diarrhoea were in Nyamira (3 percent), Mandera (3 percent), and Nyeri (5 percent).

Prompt treatment, including oral rehydration therapy, is important in treating diarrhoea. Table 10.7 shows the percentage of children with diarrhoea who according to the mother's report received specific treatments, by background characteristics. Advice or treatment was sought from a health provider in the case of 58 percent of children with diarrhoea. Children age 6-11 months (65 percent), male children (59 percent), and children with bloody diarrhoea (74 percent) were more likely than their counterparts to have received advice or treatment from a health facility or provider. Considering regional differentials, treatment or advice was least likely to be sought from a health facility or provider for children with diarrhoea in North Eastern (44 percent) and Western (47 percent) regions and most likely in Coast (65 percent). Children of mothers with no education (63 percent) and children of mothers in the lowest wealth quintile (61 percent) were more likely than others to be taken to a health facility or provider for advice or treatment.

Table 10.7 Diarrhoea treatment

Among children under age five who had diarrhoea in the two weeks preceding the survey, the percentage for whom advice or treatment was sought from a health facility or provider, the percentage given oral rehydration therapy (ORT), the percentage given increased fluids, the percentage given ORT or increased fluids, and the percentage who were given other treatments, by background characteristics, Kenya 2014

Background characteristic	Percentage of children with diarrhoea for whom advice or treatment was sought from a health facility or provider[1]	Oral rehydration therapy (ORT)						Other treatments							Number of children with diarrhoea
		Fluid from ORS packets	Fluid from ORS packets and zinc	Home-made fluids	Either ORS or home-made fluids	In-creased fluids	ORT or in-creased fluids	Antibiotic drugs	Anti-motility drugs	Zinc supple-ments	Intra-venous solution	Home remedy/ other	Missing	No treat-ment

Note: ORT includes fluid prepared from oral rehydration salt (ORS) packets, homemade sugar-salt solution, and other homemade fluids. Total includes 56 children for whom information on type of diarrhoea is missing.
[1] Excludes pharmacy, shop, and traditional practitioner

Oral rehydration therapy (ORT) involves giving a child a solution prepared from oral rehydration salts (ORS) or other homemade fluids. Table 10.7 shows that 54 percent of children with diarrhoea were treated with an ORS solution and 57 percent with homemade fluids. Overall, 78 percent received some form of ORT, either ORS or other homemade fluids. Simply increasing the fluids a child receives can help prevent dehydration. Twenty-two percent of children were given increased fluids. Eighty-two percent were given ORT or increased fluids.

Table 10.7 also shows the proportions of children receiving treatments other than ORT or increased fluids. Eight percent of children with diarrhoea were given zinc supplements, while 7 percent received both zinc supplements and ORS. Sixteen percent of children with diarrhoea received antibiotic drugs, 1 percent were given anti-motility drugs, and 2 percent were treated with intravenous fluids. Twenty percent were treated with home remedies. Eleven percent of children with diarrhoea did not receive any treatment at all.

Treatment practices varied considerably across subgroups of children. For example, as Table 10.7 shows, use of ORT or increased fluids was lowest among children less than age 6 months (59 percent) and highest among children age 12-23 months (86 percent). There are also marked regional differences in use of ORT or increased fluids, from a high of 88 percent in Nairobi to a low of 75 percent in North Eastern.

Use of ORT or increased fluids is higher among children of mothers with a secondary or higher education (85 percent) than among children of mothers at other educational levels.

Mothers are encouraged to continue feeding children with diarrhoea normally and to increase the amount of fluids. These practices help to reduce dehydration and minimise the adverse consequences of diarrhoea on the child's nutritional status. To obtain information on the extent to which these feeding practices are used, mothers of children under age 5 who had diarrhoea during the two weeks before the survey were asked about the amount of fluids and food they gave during the diarrhoeal episode.

Table 10.8 shows that 37 percent of children with diarrhoea were given the same amount of fluid as usual, 22 percent were given more, 25 percent were given somewhat less, and 14 percent were given much less than the usual amount. Only 2 percent were not given any fluids. Regarding the amount of food children with diarrhoea received, 32 percent were given the same amount of food as usual, and 3 percent were offered more to eat. On the other hand, 31 percent were given somewhat less than the usual amount of food, 18 percent were given much less than the usual amount, and 7 percent ate nothing during the diarrhoeal episode. Only 15 percent of children received increased fluids with continued feeding. Fifty-three percent of children with diarrhoea continued feeding and were given ORT and/or increased fluids.

Table 10.8 Feeding practices during diarrhoea

Percent distribution of children under age five who had diarrhoea in the two weeks preceding the survey by amount of liquids and food offered compared with normal practice, the percentage of children given increased fluids and continued feeding during the diarrhoea episode, and the percentage of children who continued feeding and were given ORT and/or increased fluids during the episode of diarrhoea, by background characteristics, Kenya 2014

Note: It is recommended that children should be given more liquids to drink during diarrhoea and food should not be reduced. Total includes 56 children for whom information on type of diarrhoea is missing.
[1] Continued feeding practices includes children who were given more, same as usual, or somewhat less food during the diarrhoea episode

Feeding practices during diarrhoeal episodes varied by background characteristics. The proportion of children who were fed optimally, that is, who continued feeding and were given ORT and/or increased fluids, generally increased with age, reaching a peak of 68 percent among children age 36-47 months. The likelihood that a child was fed according to the optimal practice was greater among urban than rural children and generally increased with both mother's education and wealth quintile. Children with diarrhoea were most often fed according to the optimal practice in Nairobi (79 percent) and least often in North Eastern (31 percent). County-level data are not presented for Table 10.7 or Table 10.8 since there are insufficient cases of children with diarrhoea.

A comparison of the results from the 2008-09 and 2014 KDHS surveys with respect to the actions taken when children have diarrhoea highlights a number of improvements in treatment practices. The proportion of children with diarrhoea taken to a health facility or provider for advice or treatment increased from 49 percent at the time of the 2008-09 KDHS to 58 percent in the 2014 KDHS. The percentage of children with diarrhoea treated with a solution prepared from an ORS packet also increased from 39 percent in 2008-09 to 54 percent in 2014. Use of zinc to treat diarrhoea in children increased from less than 1 percent (0.2 percent) in 2008-09 to 8 percent in 2014. While treatment practices improved in a number of ways in the past five years, there are also a number of areas of concern. The proportion of children receiving no treatment increased from 13 percent in the 2008-09 KDHS to 18 percent in the 2014 KDHS. Also, there was no change in the proportion of children with diarrhoea given increased fluids with continued feeding.

10.6 KNOWLEDGE OF ORS PACKETS AND ZINC TABLETS

To ascertain how widespread knowledge of oral rehydration salt (ORS) is in Kenya, women age 15-49 with a live birth in the five years preceding the survey were asked whether they knew about ORS packets. Women were also asked whether they had heard of zinc tablets as a treatment for diarrhoea.

Table 10.9 shows that 93 percent of women age 15-49 with a live birth in the five years preceding the survey have heard of ORS packets. This represents a substantial increase from the 78 percent of mothers who knew about ORS packets at the time of the 2008-09 KDHS. With regard to differentials in ORS knowledge, the proportion of women who had heard about ORS packets was below 90 percent only among those age 15-19 (89 percent), those in North Eastern (81 percent), those with no education (82 percent), and those in the lowest wealth quintile (87 percent).

While most women with a birth in the five years before the survey knew about ORS packets, only around 1 in 6 women were aware of zinc tablets (17 percent). Women in urban areas (21 percent), women in Western and Nyanza (22 percent each), women with a secondary or higher education (24 percent), and women in the fourth and highest wealth quintiles (21 percent each) were more likely to have heard of zinc tablets than other women.

Table 10.9 Knowledge of ORS packets

10.7 DISPOSAL OF CHILDREN'S STOOLS

Unsafe disposal of human faeces spreads disease, either by direct contact or through indirect transmission. Hence, the proper disposal of children's stools is extremely important in preventing the spread of disease. Children's stools are considered to be safely disposed of if the child uses a toilet or latrine or the stools are put or rinsed into a toilet or latrine or buried.

Table 10.10 presents information on the disposal of stools of children under age 5. Overall, 83 percent of children had their last stool disposed of safely. This represents an improvement from the 78 percent reported in the 2008-09 KDHS. Children whose mothers had no education (49 percent), children in the lowest wealth quintile (57 percent), and children in the North Eastern region (62 percent) were least likely to have their last stool disposed of safely. Children in the Central and Western regions (95 percent each) were most likely to have their last stool disposed of safely.

Table 10.10 Disposal of children's stools

Percent distribution of youngest children under age five living with the mother by the manner of disposal of the child's last faecal matter, and percentage of children whose stools are disposed of safely, according to background characteristics, Kenya 2014

NUTRITION OF CHILDREN AND WOMEN 11

Lucy Gathigi Maina, Andolo Miheso, Annah W. Wamae, Henry Z. Osoro

Key Findings

- Twenty-six percent of children under age 5 are stunted, 4 percent are wasted, and 11 percent are underweight.
- Ninety-nine percent of children have ever been breastfed and 61 percent of children less than age 6 months are exclusively breastfed.
- Complementary foods are generally introduced at the recommended age; 81 percent of breastfed children age 6-9 months received complementary foods in addition to being breastfed within the 24 hours preceding the survey.
- Only 22 percent of children are fed in accordance with the three recommended infant and young child feeding practices.
- Seventy-two percent of children age 6-59 months received vitamin A supplements in the past six months.
- Fifty-one percent of children age 12-59 months received deworming medication in the past six months.
- Nine percent of women age 15-49 are thin or undernourished (BMI <18.5 kg/m^2); 33 percent of women are either overweight or obese (BMI ≥25 kg/m^2), with 10 percent being obese (BMI ≥30 kg/m^2).
- Only 8 percent of women took iron tablets daily for 90 or more days during the pregnancy of their last birth.
- Thirty-one percent of women took deworming medication during their last pregnancy.

Good nutrition is a prerequisite for the national development of countries and for the well-being of individuals. The 2010 Constitution of Kenya recognises adequate food and nutrition as a human right. It states that every person has the right to be free from hunger and the right to adequate food of acceptable quality (Article 43) and that every child has the right to basic nutrition (Article 53). Furthermore, the Government of Kenya's 2011 Food and Nutrition Security Policy states that nutrition is central to human development in the country (Government of Kenya, 2011).

Adequate nutrition is critical to children's growth and development. The period from birth to age 2 years is especially important for optimal physical, mental, and cognitive growth, health, and development. Unfortunately, this period is often marked with nutrient deficiencies that interfere with optimal growth and may cause common childhood illnesses such as diarrhoea and acute respiratory infections.

A woman's nutritional status has important implications for her health as well as for the health of her children. Malnutrition in women results in reduced productivity, increased susceptibility to infections, slowed recovery from illness, and a heightened risk of adverse pregnancy outcomes. For example, a woman with poor nutritional status, as indicated by a low body mass index (BMI), short stature, or micronutrient deficiencies, has a greater risk of obstructed labour, of having a baby with a low birth weight, of death from postpartum haemorrhage, and of morbidity for both herself and her baby.

This chapter covers the nutritional concerns for children and women. Specifically, it presents information on the nutritional status of children and women based on anthropometric measurements, infant and young child feeding practices including breastfeeding and complementary feeding, micronutrient intake among children and women, and salt iodisation.

11.1 NUTRITIONAL STATUS OF CHILDREN

The nutritional status of children under age 5 is an important measure of children's health. Anthropometric data collected in the 2014 KDHS permit estimation of the overall nutritional status of Kenyan children and analysis of nutrition status by background characteristics. This allows identification of subgroups of the child population that are at increased risk of faltered growth, disease, impaired mental development, and death.

11.1.1 Measurement of Nutritional Status among Young Children

In the 2014 KDHS, height and weight measurements were obtained for children born since January 2009. The height and weight data are used to compute three summary indices of nutritional status: height-for-age, weight-for-height, and weight-for-age.

For this report, the summary indicators of the nutritional status of children were calculated using growth standards published by the World Health Organization (WHO) in 2006. These standards were generated using data collected in the WHO Multicentre Growth Reference Study (WHO, 2006). The study, whose sample included 8,440 children in six countries, was designed to provide a description of how children should grow under optimal conditions. The WHO Child Growth Standards can therefore be used to assess children all over the world, regardless of ethnicity, social and economic influences, and feeding practices. Each of the three nutritional status indicators described below is expressed in standard deviation units from the median of the WHO Multicentre Growth Reference Study sample.

The height-for-age index provides an indicator of linear growth retardation and cumulative growth deficits. Children whose height-for-age Z-score is below minus two standard deviations (-2 SD) from the median of the WHO reference population are considered short for their age (stunted) and are chronically malnourished. Children who are below minus three standard deviations (-3 SD) are considered severely stunted. Stunting reflects failure to receive adequate nutrition over a long period of time and is affected by recurrent and chronic illness. Height-for-age, therefore, represents the long-term effects of malnutrition in a population and is not sensitive to recent, short-term changes in dietary intake.

The weight-for-height index measures body mass in relation to body height or length and describes current nutritional status. Children with Z-scores below minus two standard deviations (-2 SD) are considered thin (wasted) and are acutely malnourished. Wasting represents the failure to receive adequate nutrition in the period immediately preceding the survey and may be the result of inadequate food intake or a recent episode of illness causing loss of weight and the onset of malnutrition. Children whose weight-for-height index is below minus three standard deviations (-3 SD) are considered severely wasted. The weight-for-height index also provides data on overweight and obesity. Children more than two standard deviations (+2 SD) above the median weight-for-height are considered overweight or obese.

Weight-for-age is a composite index of height-for-age and weight-for-height. It takes into account both chronic and acute malnutrition. Children whose weight-for-age is below minus two standard deviations (-2 SD) are classified as underweight. Children whose weight-for-age is below minus three standard deviations (-3 SD) are considered severely underweight.

11.1.2 Data Collection

Measurements of height and weight were obtained for all children born since January 2009 and listed in the Household Questionnaire. The survey included children who were not biological offspring of the women interviewed. Each interviewing team carried a scale and a measuring board. The scales were electronic SECA scales with a digital screen. They were designed and manufactured under the authority of the United Nations Children's Fund (UNICEF). The scale allowed weighing of very young children through an automatic mother-child adjustment that eliminated the mother's weight while she was standing on the scale with her baby. Weight was measured to the nearest 100 grams (g). Height measurements were made using height/length (Shorr) boards, manufactured by Shorr Productions for use in survey settings.

Children younger than 24 months and those whose age was unknown and who were less than 87 centimetres were measured lying down on the board (recumbent length). Standing height was measured for older children.

A total of 21,435 children under age 5 were eligible for weight and height measurements. Of these children, 3 percent had missing values for height or weight and 1 percent had height or weight data considered to be out of range for their age and were not included in the final analysis. Thus, this chapter includes data for 96 percent of the 21,435 (unweighted) children under age 5 who were present in sampled households at the time of the survey.

11.1.3 Measures of Child Nutritional Status

Height-for-age

Table 11.1 and Figure 11.1 present the nutritional status of children under age 5 by various background characteristics. Nationally, 26 percent of children are stunted, while 8 percent are severely stunted. Analysis of this indicator by age group shows that stunting is highest in children age 18-23 months (36 percent) and 24-35 months (34 percent). Similar results are observed for children who are severely stunted; children age 18-23 months are the most affected (12 percent). Stunting levels are higher among boys (30 percent) than girls (22 percent) and higher among children whose mothers reported they were very small at birth (43 percent) than among those who were average or larger at birth (24 percent).

Stunting is higher among rural children (29 percent) than urban children (20 percent). At the regional level, Coast (31 percent), Rift Valley and Eastern (each 30 percent) have the highest proportions of stunted children, while Nairobi (17 percent) and Central (18 percent) have the lowest. Stunting in children generally decreases with education of the mother. Children of mothers who did not complete primary school (34 percent) or who have no education (31 percent) are more likely to be stunted than children of mothers with a secondary or higher education (17 percent). Table 11.1 further shows that stunting in children decreases as household wealth increases, from 36 percent to 14 percent.

Weight-for-height

Table 11.1 also shows the nutritional status of children under age 5 as measured by wasting or low weight-for-height. Nationally, 4 percent of children are wasted and 1 percent are severely wasted. Wasting levels are highest among children in the age groups 6-8 months and 9-11 months (each 7 percent). Typically during this period, children are introduced to complementary foods, which may vary in quality and quantity, and are more vulnerable to diseases. Wasting is higher (9 percent) among children whose mothers are thin (BMI <18.5 kg/m^2) than among other children. The North Eastern region (13 percent) has the highest levels of wasting, while the Western, Nyanza, and Central regions have the lowest (each 2 percent). Children whose mothers have no education have a higher chance of wasting (10 percent) than children whose mothers have some education (4 percent or less). Wasting in children generally decreases with increasing household wealth.

Weight-for-age

Table 11.1 also shows that 11 percent of Kenyan children are underweight (low weight-for-age), with 2 percent classified as severely underweight. Peak levels of low weight-for-age are found among children older than age 12 months. The percentage underweight is slightly higher among boys (12 percent) than girls (10 percent); also, it is higher among children whose mother is thin (24 percent) than children of mothers with a higher BMI (11 percent or less) and among rural children (13 percent) than urban children (7 percent). North Eastern has the highest proportion (19 percent) of underweight children, while Nairobi has the lowest (4 percent). The proportion underweight decreases as mother's educational level increases and as household wealth increases.

Table 11.1 Nutritional status of children

Percentage of children under five years classified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, by background characteristics, Kenya 2014

Background characteristic	Height-for-age[1]			Weight-for-height				Weight-for-age				Number of children

Note: Table is based on children who stayed in the household on the night before the interview. Each of the indices is expressed in standard deviation units (SD) from the median of the WHO Child Growth Standards adopted in 2006. The indices in this table are NOT comparable to those based on the previously used NCHS/CDC/WHO reference.

Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight.

[1] Recumbent length is measured for children under age 2, or in the few cases when the age of the child is unknown and the child is less than 87 cm; standing height is measured for all other children.

[2] Includes children who are below -3 standard deviations (SD) from the WHO Child Growth standards population median

[3] Excludes children whose mothers were not interviewed. Data only available from respondents to the full questionnaire.

[4] First-born twins (triplets, etc.) are counted as first births because they do not have a previous birth interval

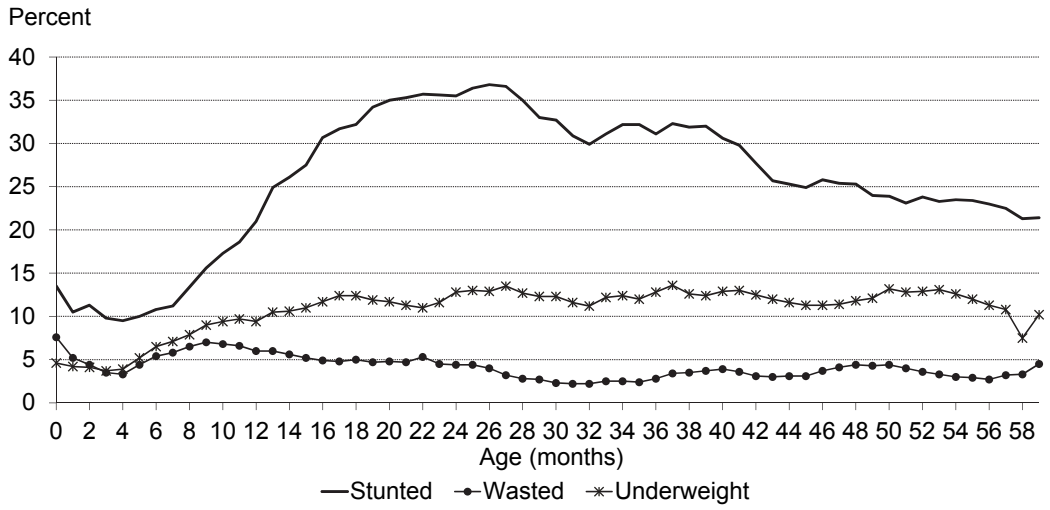
[5] Includes children whose mothers are deceased

[6] Excludes children whose mothers were not weighed and measured, children whose mothers were not interviewed, and children whose mothers are pregnant or gave birth within the preceding 2 months. Mother's nutritional status in terms of BMI (Body Mass Index) is presented in Table 11.10.

[7] For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire

Figure 11.1 shows that Kenyan children are more likely to experience stunting than to be wasted or underweight. Additionally, the risk of stunting peaks at age 18 to 28 months.

Figure 11.1 **Nutritional status of children by age**



Note: *Stunting* reflects chronic malnutrition; *wasting* reflects acute malnutrition; *underweight* reflects chronic or acute malnutrition or a combination of both. Plotted values are smoothed by a five-month moving average.

KDHS 2014

At the county level (Table 11.1C), West Pokot and Kitui have the highest proportions (46 percent each) of stunted children. Other counties reporting high proportions of stunting include Kilifi (39 percent), Mandera (36 percent), and Bomet (36 percent). Nyeri, Garissa, and Kiambu counties have the lowest proportion of stunted children, each 16 percent or less. Wasting is concentrated in the north: more than 11 percent of children in Garissa, Wajir, Mandera, Marsabit, Turkana, West Pokot, and Samburu are wasted, topping out at 23 percent in Turkana. The counties with the lowest proportion of wasted children are Siaya and Kisumu (each 1 percent or less). The table also shows that one-quarter of children or more are underweight in five counties: Mandera, Marsabit, Turkana, West Pokot, and Samburu. Four percent or less of children in Nyeri and Nairobi are underweight.

Table 11.1C Nutritional status of children

Percentage of children under five years classified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, by county, Kenya 2014

Each of the indices is expressed in standard deviation units (SD) from the median of the WHO Child Growth Standards adopted in 2006. The indices in this table are NOT comparable to those based on the previously used NCHS/CDC/WHO reference.

Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight.

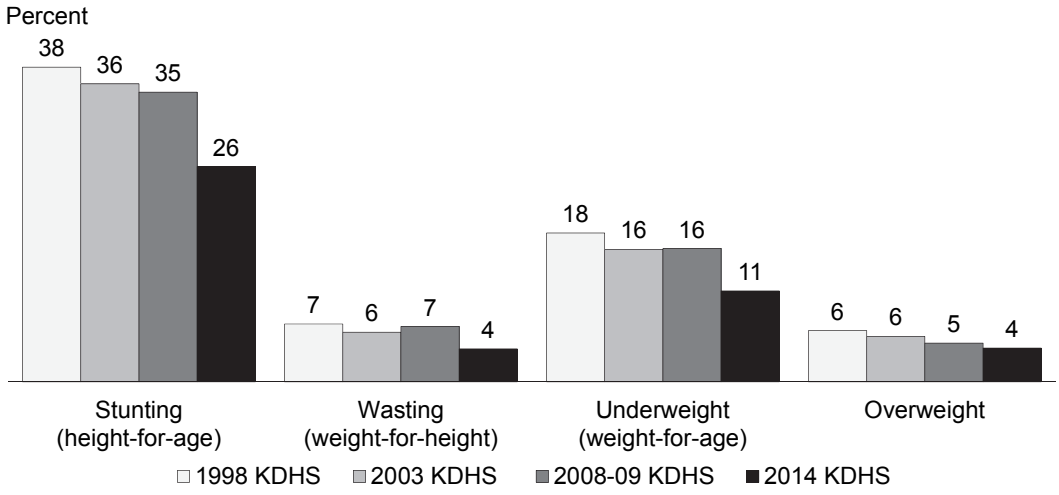
[1] Recumbent length is measured for children under age 2, or in the few cases when the age of the child is unknown and the child is less than 87 cm; standing height is measured for all other children.

[2] Includes children who are below -3 standard deviations (SD) from the WHO Child Growth standards population median

11.1.4 Trends in Children's Nutritional Status

Figure 11.2 shows trends in children's nutritional status since 1998. Comparison of KDHS data over time indicates an overall improvement in children's nutritional status in Kenya. Since 1998, stunting has declined from 38 percent to 26 percent, wasting has declined from 7 percent to 4 percent, and the proportion of underweight children has declined from 18 percent to 11 percent. Kenya has met the 2015 Millennium Development Goal (MDG) target of reducing the prevalence of underweight children under age 5 to 11 percent (Ministry of Devolution and Planning, 2013).

Figure 11.2 **Trends in nutritional status of children under 5 years**



Note: The data are based on the WHO Child Growth Standards adopted in 2006. Data for 1998 were collected only for children whose mothers were interviewed; for other surveys, data were collected for all children listed in the Household Questionnaire. Data from 1998 exclude North Eastern region and some northern districts in the Eastern and Rift Valley regions.

11.2 BREASTFEEDING AND COMPLEMENTARY FEEDING

Feeding practices play a critical role in child development. Poor feeding practices can adversely impact the health and nutritional status of children, in turn resulting in direct consequences for their mental and physical development. The duration and intensity of breastfeeding also affect a mother's period of postpartum infertility and, hence, the length of the birth interval and fertility levels.

11.2.1 Initiation of Breastfeeding

Early initiation of breastfeeding is important for both the mother and the child. Early suckling stimulates the release of prolactin, which helps in the production of milk, and oxytocin, which is responsible for the ejection of milk. It also stimulates contraction of the uterus after childbirth and reduces postpartum blood loss. The first liquid to come from the breast, known as colostrum, is produced in the first few days after delivery. Colostrum is highly nutritious and contains antibodies that provide natural immunity to the infant. It is recommended that children be fed colostrum immediately after birth (within one hour) and that they continue to be exclusively breastfed even if the regular breast milk has not yet started to flow. Prelacteal feeding, giving food to newborns before the initiation of breastfeeding, is not recommended.

Table 11.2 shows the percentage of last-born children born in the two years preceding the survey according to whether they were ever breastfed, when they began breastfeeding, and whether they were fed anything other than breast milk prior to the commencement of breastfeeding. Ninety-nine percent of children have been breastfed for some period of time, with negligible differences by background characteristics. Nearly two-thirds of children (62 percent) were breastfed within one hour of birth. The vast majority (91 percent) of children were breastfed within one day of birth.

Initiation of breastfeeding in the first hour after birth varies somewhat by background characteristics. Eighty-one percent of children in the North Eastern region were breastfed within one hour of birth, as compared with 48 percent of children in the Central region. Mothers with no education (76 percent) were more likely to initiate breastfeeding in the first hour than those with some education (65 percent or less). Mothers in the lowest wealth quintile (67 percent) were more likely to initiate early breastfeeding than those in higher wealth quintiles (64 percent or less).

Table 11.2 Initial breastfeeding

Among last-born children who were born in the two years preceding the survey, the percentage who were ever breastfed and the percentages who started breastfeeding within one hour and within one day of birth; and among last-born children born in the two years preceding the survey who were ever breastfed, the percentage who received a prelacteal feed, by background characteristics, Kenya 2014

	Among last-born children born in the past two years:				Among last-born children born in the past two years who were ever breastfed:	
Background characteristic	Percentage ever breastfed	Percentage who started breastfeeding within 1 hour of birth	Percentage who started breastfeeding within 1 day of birth[1]	Number of last-born children	Percentage who received a prelacteal feed[2]	Number of last-born children ever breastfed

Note: Table is based on last-born children born in the two years preceding the survey regardless of whether the children are living or dead at the time of interview. Total includes two children with missing information on assistance at delivery and six children with missing information on place of delivery. Figures in parentheses are based on 25-49 unweighted cases.
[1] Includes children who started breastfeeding within one hour of birth
[2] Children given something other than breast milk during the first three days of life
[3] Doctor, nurse or midwife

The practice of giving prelacteal feeds is discouraged because it limits the frequency of suckling by the infant and exposes the baby to the risk of infection. Sixteen percent of children born in the last two years were given prelacteal feeds within the first three days of life. Prelacteal feeding varies by assistance at and place of delivery, residence, and region. Children whose birth was assisted by a health professional and children who were delivered at a health facility are less likely to receive prelacteal feeds (each 11 percent) than their counterparts who were delivered without health professional assistance or who were

delivered at home (each 24 percent). Prelacteal feeding is higher among children of mothers in rural areas (17 percent) than among children of mothers in urban areas (12 percent). Among the regions, the highest proportion of children receiving a prelacteal feed is observed in Western (25 percent), while the lowest is seen in Eastern (6 percent).

The 2014 KDHS initiation of breastfeeding results are not fully comparable to those of the 2008-09 KDHS as the sample included for reporting this indicator has changed from children born in the five years to children born in the two years preceding the survey.

11.2.2 Breastfeeding Status by Age

UNICEF and WHO recommend that children be exclusively breastfed during the first six months of life and that children be given solid and semisolid complementary foods in addition to continued breastfeeding from six months until 24 months or more when the child is fully weaned. Exclusive breastfeeding is recommended because breast milk is uncontaminated and contains all of the nutrients necessary for children in the first several months of life. In addition, the mother's antibodies in breast milk provide immunity to disease. Early supplementation is discouraged for several reasons. First, it exposes infants to pathogens and increases their risk of infection, especially disease. Second, it decreases infants' intake of breast milk, and therefore suckling, which reduces breast milk production. Third, in low-resource settings, supplementary food is often nutritionally inferior.

After six months, a child requires adequate complementary foods for normal growth. Lack of appropriate complementary feeding may lead to malnutrition and illness, which in turn may lead to death. However, even with complementary feeding, the child should continue to be breastfed for two years or more.

Interviewers obtained information on complementary feeding by asking mothers about the current breastfeeding status of all children under age 5 and, for the youngest child born in the two-year period before the survey and living with the mother, foods and liquids given to the child the day and night before the survey.

Table 11.3 shows the percent distribution of youngest children under age 2 living with their mother by breastfeeding status and the percentage of children under age 2 using a bottle with a nipple, according to age in months. Exclusive breastfeeding for the first six months in Kenya is 61 percent for children under age 6 months (Table 11.3 and Figure 11.3). Among subgroups, the percentage of children exclusively breastfed decreases sharply from 84 percent of infants age 0-1 month to 63 percent of infants age 2-3 months and, further, to 42 percent of infants age 4-5 months.

In addition to receiving breast milk, 10 percent of children under age 6 months receive plain water, 10 percent receive other milk, and 15 percent are given complementary foods. Contrary to recommendations, 2 percent of children age 0-1 months, 13 percent of children age 2-3 months and 27 percent of children age 4-5 months receive complimentary foods. After age 6 months, a majority of children are receiving complementary foods in addition to breast milk, as recommended; however, 19 percent of children age 6-9 months did not receive complementary foods the day or night preceding the survey.

Eleven percent of children under age 6 months and 30 percent of children age 6-9 months used a bottle with a nipple the day or night preceding the survey. Bottle feeding is a concern because of the possible contamination due to unsafe water and lack of hygiene in its preparation; it also may reduce the child's interest in breastfeeding, with a consequential decline in the mother's milk production.

It is recommended to continue breastfeeding a child until 2 years of age. The duration of breastfeeding in Kenya is long, with at least half of children being breastfed until 2 years. The proportion of children who are currently breastfeeding decreases with increasing child age with 88 percent among children age 12-17 months and to 61 percent among children age 18-23 months.

Table 11.3 Breastfeeding status by age

Percent distribution of youngest children under two years who are living with their mother by breastfeeding status and the percentage currently breastfeeding; and the percentage of all children under two years using a bottle with a nipple, according to age in months, Kenya 2014

		Breastfeeding status

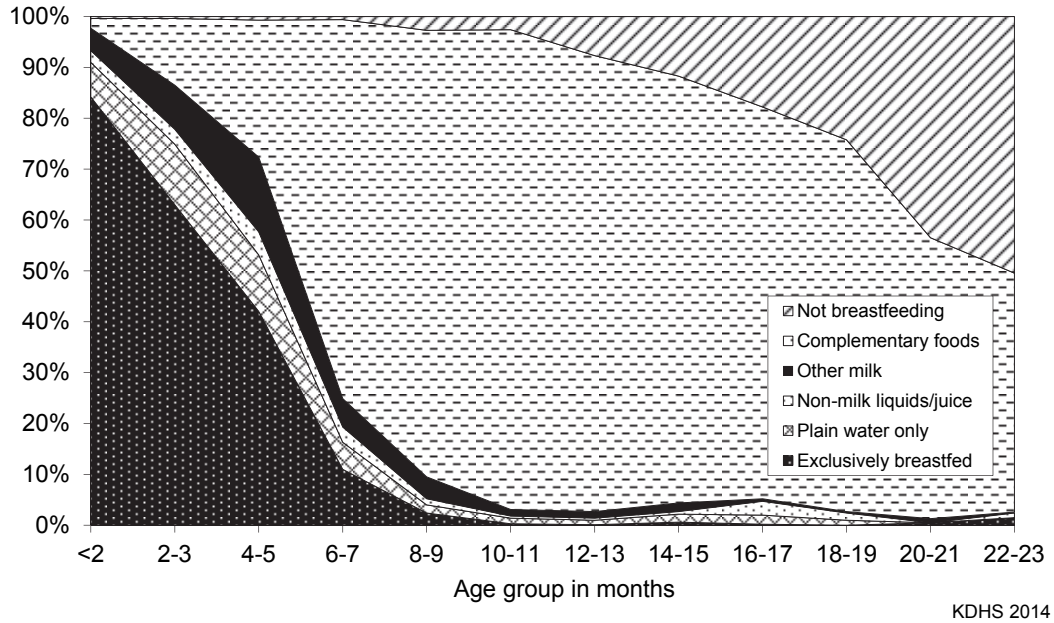
12-23	24.6	0.4	0.9	1.0	0.8	72.2	100.0	75.4	1,700	22.2	1,838
20-23	46.9	1.0	0.1	0.4	0.5	51.2	100.0	53.1	502	16.3	569

Note: Breastfeeding status refers to a "24-hour" period (yesterday and last night). Children who are classified as breastfeeding and consuming plain water only consumed no liquid or solid supplements. The categories of not breastfeeding, exclusively breastfed, breastfeeding and consuming plain water, non-milk liquids, other milk, and complementary foods (solids and semi-solids) are hierarchical and mutually exclusive, and their percentages add to 100 percent. Thus children who receive breast milk and non-milk liquids and who do not receive other milk and who do not receive complementary foods are classified in the non-milk liquid category even though they may also get plain water. Any children who get complementary food are classified in that category as long as they are breastfeeding as well.

[1] Non-milk liquids include juice, juice drinks, clear broth or other liquids

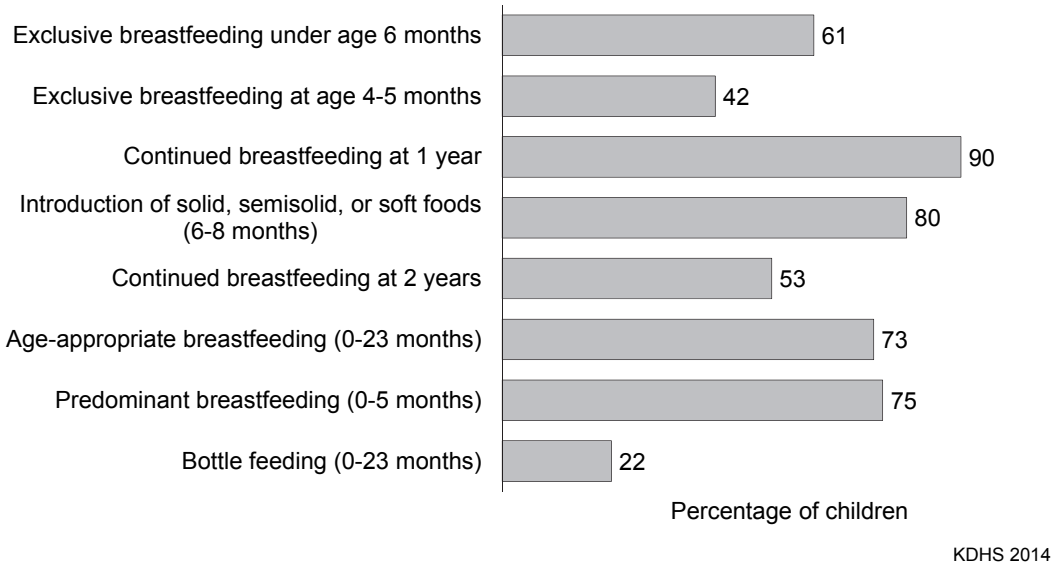
Figure 11.3 Infant feeding practices by age



KDHS 2014

Figure 11.4 shows the infant and young child feeding (IYCF) indicators of breastfeeding status. As mentioned previously, 61 percent of children under age 6 months and 42 percent of children age 4-5 months are exclusively breastfed, and 75 percent of children under age 6 months are predominantly breastfed.[1] Figure 11.4 also shows that 90 percent of children continue breastfeeding at age 1 and that 53 percent continue doing so at age 2. Eighty percent of children age 6-8 months have been introduced to solid, semisolid, or soft foods. Twenty-two percent of children age 0-23 months used a bottle with a nipple the day or night preceding the survey.

Figure 11.4 **IYCF indicators on breastfeeding status**



The proportion of children younger than age 6 months who are exclusively breastfed has markedly increased from 32 percent in the 2008-09 KDHS to the current 61 percent. The proportion of children less than age 6 months using a bottle with a nipple has also noticeably decreased, from 25 percent in 2008-09 to 11 percent in 2014. However, use of a bottle with a nipple remains of concern among children age 6-23 months. Bottle feeding remains unchanged among children age 6-9 months at 30 percent, while the proportion among children age 12-23 months has increased from 12 percent in 2008-09 to 22 percent in 2014.

11.2.3 Duration of Breastfeeding

Table 11.4 provides information on the median duration of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among children born in the three years preceding the survey. The median duration of any breastfeeding in Kenya is 21.0 months. Differences in the median duration of breastfeeding by background characteristics are small except by region. The median duration of any breastfeeding is longest in Eastern (24.5 months) and shortest in North Eastern region (19.4 months).

Table 11.4 also shows the median duration of predominant breastfeeding, which is defined as exclusive breastfeeding or breastfeeding in combination with plain water and/or non-milk liquids only. The median duration of predominant breastfeeding is 4.4 months.

Since the 2008-09 KDHS, the median duration of exclusive breastfeeding has increased from 0.7 to 3.3 months, and the median duration of predominant breastfeeding has increased from 2.2 to 4.4 months.

[1] Children who are exclusively breastfed, children who breastfeed and consume plain water, and children who are breastfed and consume non-milk liquids or juice.

Table 11.4 Median duration of breastfeeding

Median duration of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among children born in the three years preceding the survey, by background characteristics, Kenya 2014

Background characteristic	Median duration (months) of breastfeeding among children born in the past three years[1]

Total	21.0	3.3	4.4
Mean for all children	21.3	4.3	5.5

Note: Median and mean durations are based on the distributions at the time of the survey of the proportion of births by months since birth. Includes children living and deceased at the time of the survey. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] It is assumed that non-last-born children and last-born children not currently living with the mother are not currently breastfeeding.
[2] Either exclusively breastfed or received breast milk and plain water, and/or non-milk liquids only

11.2.4 Types of Complementary Foods

UNICEF and WHO recommend the introduction of solid or semi-solid food to infants around age 6 months because by that age breast milk alone is no longer sufficient to maintain a child's optimal growth. In the transition to eating the family diet, children from age 6 months should be fed small quantities of solid and semisolid foods throughout the day while continuing to breastfeed up to age 2 or beyond. Table 11.5 presents the percentages of youngest children under age 2 who are living with their mother by types of foods consumed in the day or night preceding the interview, according to their breastfeeding status.

Table 11.5 shows that, in Kenya, 80 percent of breastfed children age 6-8 months are fed solid or semisolid foods in addition to being breastfed within the 24 hours before the survey. This is substantially higher than the percentage of breastfeeding children fed complementary foods at age 4-5 months (27 percent) or age 2-3 months (13 percent) when the introduction of complementary foods is not recommended.

Overall, 92 percent of breastfed children age 6-23 months receive solid or semisolid complementary foods. The most common foods given to breastfeeding children age 6-23 months are foods made from grains (80 percent), fruits and vegetables rich in vitamin A (64 percent), food made from roots and tubers (38 percent), and other fruits and vegetables (33 percent). Children are also fed protein-rich

foods such as legumes and nuts (25 percent); meat, fish, and poultry (21 percent); and eggs (17 percent). Thirteen percent are fed cheese, yogurt, and other milk products, and 5 percent are given fortified baby foods. Other than breast milk, liquids fed to children in this age group include other liquids such as juice or clear broth (63 percent) and other milk (49 percent). Five percent of breastfeeding children age 6-23 months are also given infant formula.

Table 11.5 also presents data on the types of complementary foods consumed by nonbreastfeeding children. Ninety-seven percent of nonbreastfeeding children age 6-23 months are fed solid or semisolid foods. The percentage of children consuming each type of complementary food or liquid is higher among nonbreastfeeding children than among breastfeeding children.

Table 11.5 Foods and liquids consumed by children in the day or night preceding the interview

Percentage of youngest children under two years of age who are living with the mother by type of foods consumed in the day or night preceding the interview, according to breastfeeding status and age, Kenya 2014

Note: Breastfeeding status and food consumed refer to a "24-hour" period (yesterday and last night).
[1] Other milk includes fresh, tinned, and powdered animal milk.
[2] Does not include plain water. Includes juice, juice drinks, clear broth, or other non-milk liquids.
[3] Includes fortified baby food
[4] Includes pumpkin, squash, carrots, yellow or orange sweet potatoes, dark green leafy vegetables, mangoes, papayas, and guavas.

11.2.5 Infant and Young Child Feeding (IYCF) Practices

Appropriate IYCF practices include breastfeeding through age 2 years, introduction of solid and semisolid foods at age 6 months, and gradual increases in the amount of food given and frequency of feeding as the child gets older. The minimum frequencies for feeding children in developing countries are based on the energy output of complementary foods. The energy needs of children are based on age-specific total daily energy requirements plus two standard deviations (to cover almost all children), minus the average energy intake from breast milk. Infants with low breast milk intake need to be fed more frequently than those with high breast milk intake. However, care should be taken that feeding frequencies do not exceed the recommended input from complementary foods because excessive feeding can result in displacement of breast milk (PAHO/WHO, 2003).

According to recommendations, breastfed children age 6-23 months should receive animal-source foods and vitamin A-rich fruits and vegetables daily (PAHO/WHO, 2003). Because first foods almost always include a grain- or tuber-based staple, it is unlikely that young children who eat food from less than three groups will receive both an animal-source food and a vitamin A-rich fruit or vegetable. Therefore,

three food groups are considered the minimum number appropriate for breastfed children (Arimond and Ruel, 2004). Breastfed infants age 6-8 months should receive complementary foods two to three times a day with one or two snacks; breastfed children age 9-23 months should receive meals three to four times a day with one or two snacks (PAHO/WHO, 2003; WHO, 2008; WHO, 2010a).

Nonbreastfed children age 6-23 months should receive milk or milk products two or more times a day to ensure that their calcium needs are met. In addition, they need animal-source foods and vitamin A-rich fruits and vegetables. Four food groups are considered the minimum number appropriate for nonbreastfed young children. Nonbreastfed children age 12-23 months should be fed meals four to five times each day, with one or two snacks (WHO, 2005; WHO, 2008; WHO, 2010a).

Table 11.6 presents summary indicators of IYCF practices in the 24 hours preceding the survey for the youngest children age 6-23 months living with their mother. Ninety-one percent of children received breast milk or milk products. Forty-one percent had an adequately diverse diet—that is, they had been given foods from the appropriate number of food groups—and 51 percent had been fed the minimum number of times appropriate for their age. The feeding practices of only 22 percent of children age 6-23 months meet the minimum standards with respect to all three IYCF practices. The IYCF indicators for minimum acceptable diet by breastfeeding status among Kenyan children age 6-23 months are summarised in Figure 11.5.

The likelihood of children being fed according to the recommended IYCF guidelines increases with age. Children in urban areas (31 percent) are more likely to be fed appropriately than their rural counterparts (17 percent). By region, adherence to IYCF feeding practices is highest in Nairobi (39 percent) and lowest in North Eastern (3 percent). Appropriate feeding increases with increasing mother's education and household wealth.

In the period between the 2008-09 KDHS and the 2014 KDHS, the definition of standard IYCF indicators changed to reflect more restrictive requirements. In order to compare the IYCF results presented here with results from the 2008-09 KDHS, the 2014 data were recalculated according to the definitions used in 2008-09. This comparison indicates that the percentage of children age 6-23 months fed in accordance with the three recommended IYCF practices decreased between 2008-09 and 2014, from 39 percent to 31 percent (data not shown).

Table 11.6 Infant and young child feeding (IYCF) practices

Percentage of youngest children age 6-23 months living with their mother who are fed according to three IYCF feeding practices based on breastfeeding status, number of food groups, and times they are fed during the day or night preceding the survey, by background characteristics, Kenya 2014

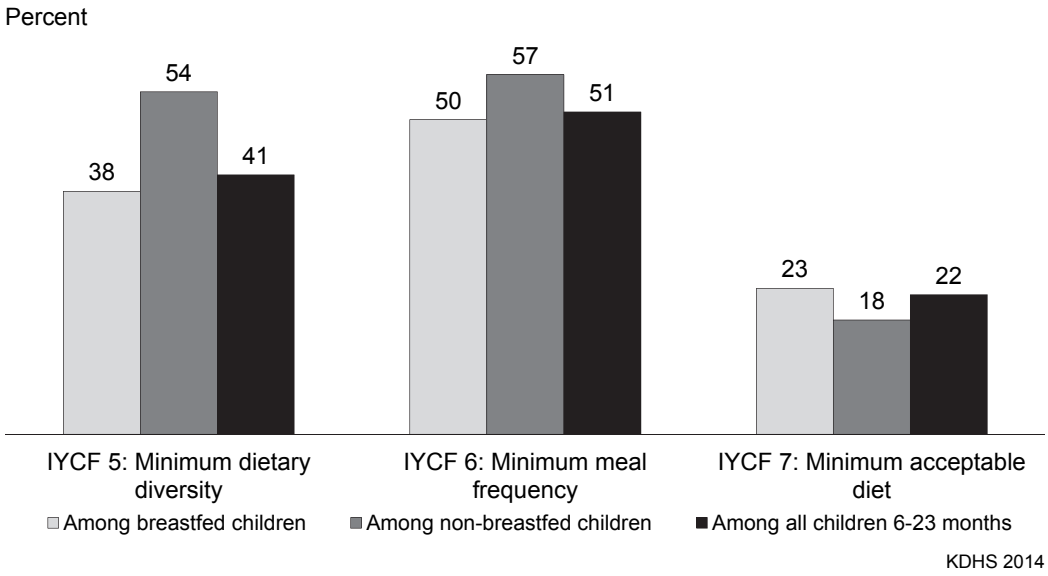
Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] Food groups: a. infant formula, milk other than breast milk, cheese or yogurt or other milk products; b. foods made from grains, roots, and tubers, including porridge and fortified baby food from grains; c. vitamin A-rich fruits and vegetables; d. other fruits and vegetables; e. eggs; f. meat, poultry, fish, and shellfish (and organ meats); g. legumes and nuts.
[2] For breastfed children, minimum meal frequency is receiving solid or semi-solid food at least twice a day for infants 6-8 months and at least three times a day for children 9-23 months
[3] Includes two or more feedings of commercial infant formula, fresh, tinned, and powdered animal milk, and yogurt
[4] For non-breastfed children age 6-23 months, minimum meal frequency is receiving solid or semi-solid food or milk feeds at least four times a day
[5] Non-breastfed children age 6-23 months are considered to be fed with a minimum standard of three Infant and Young Child Feeding Practices if they receive other milk or milk products at least twice a day, receive the minimum meal frequency, and receive solid or semi-solid foods from at least four food groups not including the milk or milk products food group
[6] Breastfeeding, or not breastfeeding and receiving two or more feedings of commercial infant formula, fresh, tinned and powdered animal milk, and yogurt
[7] Children are fed the minimum recommended number of times per day according to their age and breastfeeding status as described in footnotes 2 and 4.

Figure 11.5 **IYCF indicators on minimum acceptable diet**



11.3 MICRONUTRIENT INTAKE AMONG CHILDREN

Micronutrient deficiency is a major contributor to childhood morbidity and mortality. Children can receive micronutrients from foods, food fortification, and direct supplementation. Table 11.7 summarises information collected on children's intake of vitamin A and iron, and their receipt of deworming medications.

Vitamin A is an essential micronutrient for the immune system that plays an important role in maintaining the epithelial tissue in the body. Severe vitamin A deficiency (VAD) can cause eye damage. VAD can also increase the severity of infections, such as measles and diarrhoeal diseases in children, and slow recovery from illness. Vitamin A is found in breast milk, other milk, liver, eggs, fish, butter, mangoes, papayas, carrots, pumpkins, dark green leafy vegetables, and some other fruits and vegetables. The liver can store an adequate amount of the vitamin for four to six months. Periodic dosing (usually every six months) with vitamin A supplements is one method of ensuring that children at risk do not develop VAD.

Overall, 72 percent of children age 6-23 months consumed foods rich in vitamin A the day or night preceding the survey. The percentage of children consuming foods rich in vitamin A increases with age. Nonbreastfeeding children (83 percent) are more likely than breastfeeding children (70 percent) to consume vitamin A-rich foods. Urban children are more likely to consume vitamin A-rich foods (84 percent) than children in rural areas (65 percent). Nairobi has the highest proportion (97 percent) of children who consumed vitamin A-rich foods, while North Eastern has the lowest (25 percent). Consumption of vitamin A-rich foods increases with increasing mother's education and household wealth.

Iron is essential for cognitive development, and low iron intake can contribute to anaemia. Iron requirements are greatest at age 6-11 months, when growth is extremely rapid. Table 11.7 shows that 33 percent of children age 6-23 months consumed foods rich in iron the day or night preceding the survey. Consumption of iron-rich foods increases with age. Nonbreastfeeding children (43 percent) are more likely than breastfeeding children (31 percent) to consume iron-rich foods. Urban children (41 percent) are more likely to consume iron-rich foods than children in rural areas (29 percent). Nyanza (47 percent) and Nairobi (46 percent) have the highest proportions of children consuming iron-rich foods, while North Eastern and Eastern have the lowest (21 percent each). Consumption of iron-rich foods increases with increasing mother's education and household wealth.

Table 11.7 shows that only 6 percent of children age 12-59 months received iron supplements in the seven days preceding the survey. Iron supplementation does not vary much by background characteristics. Infection with helminths or intestinal worms has an adverse impact on the physical development of children and is associated with high levels of iron deficiency anaemia and other nutritional deficiencies. In Kenya, policy requires that children age 12-59 months receive deworming medication once every six months since regular treatment is a simple, cost-effective measure to address these infections. Fifty-one percent of children age 12-59 months received deworming medication in the six months

Table 11.7 Micronutrient intake among children: Vitamin A, iron, and deworming medication

Among youngest children age 6-23 months who are living with their mother, the percentages who consumed vitamin A-rich and iron-rich foods in the day or night preceding the survey, and among all children 12-59 months, percentages who were given iron supplements in the past seven days, and who were given deworming medication in the six months preceding the survey, by background characteristics, Kenya 2014

Note: Information on iron supplements and deworming medication is based on the mother's recall. Total for children age 6-23 months includes four children with missing information on breastfeeding status. Total for children age 12-59 months 53 children with missing information on breastfeeding status.
na = Not applicable
[1] Includes meat (and organ meat), fish, poultry, eggs, pumpkin, squash, carrots, orange or yellow sweet potatoes, dark green leafy vegetables, mango, papaya, guava, and other locally grown fruits and vegetables that are rich in vitamin A
[2] Includes meat (including organ meat), fish, poultry, and eggs
[3] Deworming for intestinal parasites is commonly done for helminths and for schistosomiasis.

before the survey. More children in urban areas (57 percent) received deworming medication than in rural areas (48 percent). Children in Central (71 percent) are more likely to receive deworming medication than those in other regions, and children in North Eastern are least likely to receive deworming medication (20 percent). The likelihood of receiving deworming medication increases with increasing mother's education and household wealth.

For the purpose of comparison with the 2008-09 KDHS, the data on receipt of deworming medication were recalculated for children age 6-59 months. The results indicate that deworming among children age 6-59 months increased from 38 percent in 2008-09 to 46 percent in 2014 (data not shown).

Table 11.8 shows that 72 percent of children age 6-59 months received vitamin A supplements in the past six months. Children who are still breastfeeding (77 percent) are more likely to be given vitamin A supplements than those who are not breastfeeding (71 percent). More children in urban areas received vitamin A supplements than in rural areas (75 percent and 70 percent, respectively). At the regional level, the proportion of children receiving vitamin A supplements is highest in Central (79 percent) and lowest in North Eastern (55 percent). The proportion of children receiving vitamin A supplements increases with increasing mother's education and household wealth.

The percentage of children receiving vitamin A supplements varies across counties (Table 11.8C). In 11 counties, more than 80 percent of children receive vitamin A supplements (Laikipia, Bungoma, Kwale, Kitui, Busia, Makueni, Mombasa, Kiambu, Nyandarua, Elgeyo Marakwet, and Isiolo). Mandera has the lowest proportion (20 percent) of children receiving vitamin A supplements.

Table 11.8 Micronutrient intake among children: Vitamin A and iodised salt

Among all children 6-59 months, the percentage who were given vitamin A supplements in the six months preceding the survey, and among all children age 6-59 months who live in households that were tested for iodised salt, the percentage who live in households with iodised salt, by background characteristics, Kenya 2014

Note: Information on vitamin A is based on both mother's recall and the immunisation card (where available).

[1] Excludes children in households in which salt was not tested.

Iodine deficiency, most frequently caused by inadequate iodine intake, has serious effects on body growth and mental development. Fortification of salt with iodine is the most common method of preventing iodine deficiency. To assess the use of iodised salt, the 2014 KDHS asked households to provide a teaspoon of salt used for cooking. The salt was tested for iodine using a rapid test kit. Virtually all children living in households tested for iodised salt have access to iodised salt (Table 11.8). There is no difference in the availability of iodised salt across the households and children's background characteristics.

11.4 IODISATION OF HOUSEHOLD SALT

Table 11.9 shows the percentage of households with salt tested for iodine content, the percentage of households without salt, and, among households with tested salt, the percentage with iodine present in the salt. Survey teams tested salt in 94 percent of households; the remaining 6 percent had no salt available. Virtually all households with tested salt have iodised salt. In all counties, over 95 percent of the households tested for iodised salt have iodised salt except Lamu, with 89 percent (Table 11.9C).

Table 11.9 Presence of iodised salt in household

11.5 NUTRITIONAL STATUS OF WOMEN

Measurements of height and weight were obtained from women in one-half of households selected in the 2014 KDHS in order to assess women's nutritional status. There are, however, sufficient cases to calculate county-level estimates of women's nutritional status. The nutritional status of women was assessed with two anthropometric indices: height and body mass index (BMI).

Short stature reflects poor socioeconomic conditions and inadequate nutrition during childhood and adolescence. In a woman, short stature is a risk factor for poor birth outcomes and obstetric complications. For example, short stature is associated with small pelvic size, which increases the likelihood of difficulty during delivery and the risk of bearing low birth weight babies. A woman is considered to be at risk if her height is below 145 cm.

BMI is expressed as the ratio of weight in kilograms to the square of height in metres (kg/m^2). BMI is used to measure thinness or obesity. A BMI below 18.5 kg/m^2 indicates thinness or acute undernutrition, and a BMI of 25.0 kg/m^2 or above indicates overweight or obesity. A BMI below 17 kg/m^2 indicates severe undernutrition and is associated with increased mortality. Low pre-pregnancy BMI, as with short stature, is associated with poor birth outcomes and obstetric complications.

To derive these indices, the 2014 KDHS took height and weight measurements among women age 15-49. Weight measurements were made using an electronic scale (SECA scale). Standing height measurements were made using height/length (Shorr) boards. Respondents for whom there was no information on height and/or weight and those who were pregnant or had given birth in the two months preceding the survey were excluded from the analysis.

According to Table 11.10, less than 1 percent of women age 15-49 are shorter than 145 cm. There are no apparent differences in height by background characteristics.

Table 11.10 Nutritional status of women

Among women age 15-49, the percentage with height under 145 cm, mean Body Mass Index (BMI), and the percentage with specific BMI levels, by background characteristics, Kenya 2014

	Height		Body Mass Index[1]								
Background characteristic	Percentage below 145 cm	Number of women	Mean Body Mass Index (BMI)	18.5-24.9 (Total normal)	<18.5 (Total thin)	17.0-18.4 (Mildly thin)	<17 (Moderately and severely thin)	≥25.0 (Total overweight or obese)	25.0-29.9 (Overweight)	≥30.0 (Obese)	Number of women

Nairobi	**0.3**	**1,662**	**25.4**	**49.7**	**2.8**	**2.6**	**0.2**	**47.6**	**31.1**	**16.5**	**1,517**
Total	0.8	14,265	23.7	58.3	8.9	6.4	2.5	32.8	22.7	10.1	13,143

Note: The Body Mass Index (BMI) is expressed as the ratio of weight in kilograms to the square of height in metres (kg/m^2).
[1] Excludes pregnant women and women with a birth in the preceding 2 months

The mean BMI among women age 15-49 is 23.7 kg/m^2. Nine percent of women of reproductive age are thin or undernourished (BMI <18.5 kg/m^2). The proportions of mild thinness (17.0-18.4 kg/m^2) and moderate and severe thinness (<17 kg/m^2) are 6 percent and 3 percent, respectively. Younger and rural women are more likely to be thin. The North Eastern region has the highest proportion (29 percent) of women who are thin, while Nairobi has the lowest (3 percent). Thinness is more common among women

with no education (25 percent) than among women at other educational levels (12 percent or less). Similarly, thinness is more common among women in the lowest wealth quintile (22 percent) and is inversely related to wealth. Women in the lowest wealth quintile (22 percent) are 5 times as likely to be thin as women in the highest wealth quintile (4 percent).

Overall, 33 percent of women are either overweight or obese (BMI ≥25 kg/m^2) with 10 percent of them being obese (BMI 30 kg/m^2 or above). The risk of being overweight or obese increases with age. Urban women are more likely to be overweight/obese (43 percent) than rural women (26 percent). Nairobi has the highest proportion (48 percent) of women who are overweight or obese, followed by Central (47 percent); the lowest proportion is observed in the North Eastern region (19 percent). The proportion of overweight or obese women increases steadily with increasing education and wealth. Women with no education (18 percent) and in the lowest wealth quintile (12 percent) are less likely to be overweight or obese compared to women with a secondary or higher education (38 percent) and women in the highest wealth quintile (50 percent).

A comparison of the 2008-09 KDHS and 2014 KDHS results indicates that the proportion of thin women (BMI <18.5 kg/m^2) has decreased marginally from 12 percent to 9 percent. The proportion of women who are overweight or obese, on the other hand, has increased from 25 percent to 33 percent, and the proportion of obese women has increased from 7 percent to 10 percent.

11.6 MICRONUTRIENT INTAKE AMONG MOTHERS

Adequate micronutrient intake by women has important benefits for both women and their children. Breastfeeding children benefit from micronutrient supplementation that mothers receive, especially vitamin A. Iron supplementation of women during pregnancy protects the mother and foetus against anaemia, which is considered a major cause of perinatal and maternal mortality. Anaemia also results in an increased risk of premature delivery and low birth weight. Finally, iodine deficiency is related to a number of adverse pregnancy outcomes, including foetal brain damage, congenital malformation, stillbirth, and prenatal death. Table 11.11 includes a number of measures that are useful in assessing micronutrient intake by women, especially during pregnancy and the postpartum period in the first two months after birth.

The findings show that 54 percent of women received a vitamin A dose during the postpartum period. The percentage of women receiving postpartum vitamin A is higher in urban areas (58 percent) than in rural areas (51 percent). Women in the Central region are most likely to take vitamin A during the postpartum period (65 percent), while women in the North Eastern region are least likely to do so (27 percent). The prevalence of postpartum vitamin A supplementation increases with increasing education. Women in the lowest wealth quintile are less likely to receive a postpartum vitamin A dose (38 percent) than their more wealthy counterparts (54 percent or higher).

Nutritional deficiencies such as anaemia are often exacerbated during pregnancy because of the additional nutrient demands associated with foetal growth. Iron status can be enhanced through iron supplementation, improving women's diets, and controlling parasites and malaria infection. Iron supplementation is necessary for pregnant women because their needs are usually too high to be met solely through food intake. In Kenya, pregnant women are advised to take combined folic acid and iron tablets daily from conception to delivery. Women may still access noncombined formulations of iron supplements in the market and within the health care system.

Table 11.11 shows that only 8 percent of women took iron tablets for 90 or more days during their last pregnancy. Five percent took iron supplements for 60-89 days, and 53 percent took the supplements for fewer than 60 days. Thirty percent of women did not take iron supplements at all during their last pregnancy. The proportion of women taking iron supplements for 90 or more days is slightly higher in urban areas and among those in the Coast and Nyanza regions.

Helminth infections are one of the factors contributing to anaemia among pregnant women. Deworming during pregnancy is a cost-effective intervention against intestinal worms that allows better absorption of nutrients and iron, thus reducing the prevalence of anaemia. In Kenya, the Ministry of Health has approved and implemented a policy to provide 500 mg of mebendazole once during pregnancy.

Table 11.11 shows that 31 percent of women took deworming medication during their last pregnancy. Women in the Coast region were most likely to take deworming medication (51 percent), while women in North Eastern were least likely to do so (7 percent). Women with no education (22 percent) were less likely than those with some education (30-34 percent) to take deworming medication.

Iodine deficiency has adverse effects on all population groups, but women of reproductive age are often the most affected. As mentioned, iodine deficiency is related to a number of adverse pregnancy outcomes. As a result, use of iodised salt by women of reproductive age is emphasised. Table 11.11 shows that virtually all women with a child born in the five years preceding the survey live in households with iodised salt.

A comparison with the 2008-09 KDHS data shows that the proportion of women who received vitamin A postpartum increased from 46 percent to 54 percent. The proportion of women taking iron supplements for 90 days or more during the pregnancy of their last birth increased marginally from 3 percent to 8 percent, and the proportion of women taking deworming medication increased from 17 percent to 31 percent.

Table 11.11 Micronutrient intake among mothers

Among women age 15-49 with a child born in the past five years, the percentage who received a vitamin A dose in the first two months after the birth of the last child, the percent distribution by number of days they took iron tablets, iron syrup, or iron and folic acid supplements during the pregnancy of the last child, and the percentage who took deworming medication during the pregnancy of the last child; and among women age 15-49 with a child born in the past five years and who live in households that were tested for iodised salt, the percentage who live in households with iodised salt, by background characteristics, Kenya 2014

[2] Excludes women in households where salt was not tested.

MALARIA 12

Rebecca Kiptui, Abdulkadir Amin Awes, James Muttunga

Key Findings

- Six in 10 households (59 percent) own at least one insecticide-treated mosquito net (ITN), while 34 percent of households have at least one net for every two people.
- Forty-eight percent of Kenyans have access to an ITN.
- Two-fifths of the household population (42 percent) slept under an ITN the night prior to the survey, and two-thirds (67 percent) of members of households with at least one ITN slept under an ITN the night prior to the survey.
- Fifty-four percent of children under age 5 slept under an ITN the night before the survey, and, among those living in households with an ITN, 77 percent slept under an ITN the night before the survey.
- Fifty-one percent of pregnant women overall slept under an ITN the night before the survey, and, among those living in households with an ITN, 77 percent slept under an ITN the night before the survey.
- Seventeen percent of women received intermittent preventive treatment (IPTp) for malaria during pregnancy; that is, they received two or more doses of SP/Fansidar, at least one during an antenatal care visit. In malaria endemic areas, 39 percent of women received IPTp.
- Twenty-three percent of children under age 5 who had a fever took ACT, and 13 percent took ACT within 24 hours of fever onset.

12.1 INTRODUCTION

Malaria is a leading cause of morbidity and mortality in Kenya, with more than 70 percent of the population at risk of infection (MOH, 2015a). Malaria transmission varies across Kenya; the four main epidemiological zones are described below.

Endemic areas: These are areas of stable malaria transmission (with altitudes ranging from 0 to 1,300 metres) around Lake Victoria in western Kenya and in the coastal regions. Rainfall, temperature, and humidity are the determinants of perennial transmission of malaria. The vector life cycle is usually short with a high survival rate due to the suitable climatic conditions. Transmission is intense throughout the year, with annual entomological inoculation rates[1] between 30 and 100.

Seasonal malaria transmission areas: This zone, in arid and semi-arid areas of the northern and south-eastern parts of the country, experiences short periods of intense malaria transmission during the rainfall seasons. Temperatures are usually high, and water pools created during the rainy season provide the malaria vectors with breeding sites. Extreme climatic conditions such as the El Niño southern oscillation lead to flooding in these areas, resulting in epidemic outbreaks with high morbidity rates due to the population's low immune status.

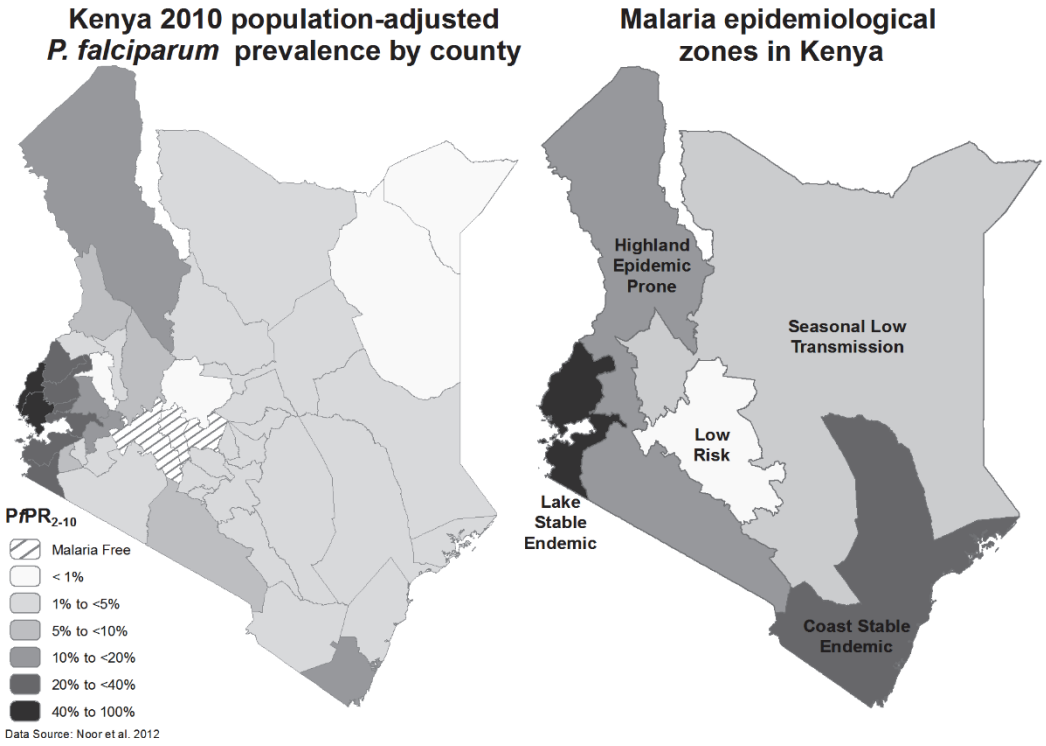
[1] The entomological inoculation rate is the average number of inoculations with malaria parasites received by a person over a period of time (usually annually). It is used to measure malaria transmission intensity and is dependent on the frequency with which people living in an area are bitten by anopheline mosquitoes carrying sporozoites (WHO, 2015a).

Highland epidemic prone areas: Malaria transmission in the western highlands of Kenya is seasonal, with considerable year-to-year variation. The epidemic phenomenon is experienced when climatic conditions favour sustainability of minimum temperatures around 18°C. This increase in minimum temperatures during periods of long rains favours and sustains vector breeding, resulting in increased intensity of malaria transmission. The whole population is vulnerable, and case fatality rates during an epidemic can be up to 10 times greater than what is experienced in regions where malaria occurs regularly.

Low risk malaria areas: This zone covers the central highlands of Kenya, including Nairobi. Temperatures are usually too low to allow completion of the sporogonic cycle of the malaria parasite in the vector. However, increasing temperatures and changes in the hydrological cycle associated with climate change are likely to increase the areas suitable for malaria vector breeding, with the introduction of malaria transmission in areas where it did not previously exist.

The highest malaria burden is in the lake endemic region, while the lowest is in the low risk and seasonal transmission areas. Map 12.1 shows the malaria burden across counties (Noor et al., 2012).

Map 12.1 **Malaria prevalence in Kenya**



The main malaria control interventions in Kenya are the following:

- Vector control via insecticide-treated nets (ITNs), indoor residual spraying (IRS), and larval source management;
- Management of malaria in pregnancy by ensuring that pregnant women receive and use ITNs and undergo intermittent preventive treatment (IPTp);
- Case management using artemisinin-based combination therapy (ACT) and improved diagnosis and treatment;
- Epidemic preparedness and response (EPR);
- Surveillance, monitoring and evaluation, and operations research;
- Advocacy, communication, and social mobilisation; and
- Cross-cutting strategies including programme management, resource mobilisation, and capacity building among counties.

Due to variation in disease patterns, not all interventions are carried out in all areas of the country. The various interventions and in what areas they are implemented should be considered in interpreting results.

Epidemiological zone	ITNs	IPTp	Case Manage-ment	EPR	Surveillance	Health Education
Endemic	•	•	•		•	•
Highland epidemic prone	•		•	•	•	•
Seasonal transmission			•	•	•	•
Low risk			•		•	•

Source: (MOH, 2010)
Note: IRS, a vector control intervention, has not been implemented since 2012 in an effort to practice insecticide resistance management. Accordingly, in this report, results for IRS are not presented.

12.2 OWNERSHIP OF MOSQUITO NETS

Nets and window screening have long been considered useful protection methods against mosquitoes and other insects (Lindsay and Gibson, 1988). Nets reduce human-vector contact by acting as a physical barrier and thus reducing the number of bites from infective vectors (Bradley et al., 1986). However, nets and screens are often not well fitted or are torn, thus allowing mosquitoes to enter or feed on the part of the body adjacent to the netting fabric during the night (Lines et al., 1987). The problem of ill-used nets and screens provides one of the motives for impregnating them with a fast-acting insecticide that will repel or kill mosquitoes (Lines et al., 1987; Hossain and Curtis, 1989).

Treatment of nets has been made possible by the availability of synthetic pyrethroids that mimic the insecticidal compounds of natural pyrethrum. Treated nets have low mammalian toxicity; are repellent, highly toxic to mosquitoes, and odourless; and have low volatility with consequent long persistence. ITNs are regarded as a promising malaria control tool that, when used by all or most members of the community, can reduce malaria transmission, morbidity, and mortality. Long-lasting insecticidal nets (LLINs) are a subset of ITNs. An LLIN is a factory-treated mosquito net made with netting material that has insecticide incorporated within or bound around the fibres. The net must retain its effective biological activity, without re-treatment for repeated washes, for three years of use under field conditions (WHO/Global Malaria Program, 2007). The current generation of LLINs last three to five years, after which the nets should be replaced.

The National Malaria Control Programme (NMCP) in Kenya distributes only LLINs; however, other varieties of treated and untreated nets may be found in markets or from other sources. In Kenya, an ITN is a net that is either an LLIN or a net treated with insecticide in the past six months.[2] The aim of the National Malaria Strategy 2009-2017 is for 80 percent of people living in endemic and epidemic prone areas to use a form of malaria prevention (MOH, 2015). Accordingly, the NMCP has undertaken efforts towards universal coverage (one net for every two people). Delivery mechanisms include mass and routine distribution of nets, social marketing, the commercial sector, and campaigns specifically targeting vulnerable groups such as young children and pregnant women.

All households interviewed in the 2014 KDHS were asked whether they owned a mosquito net and, if so, how many. Respondents were also asked to show the mosquito nets they owned to the interviewer so that the interviewer could identify the brand and type. Table 12.1 shows the percentage of households with at least one mosquito net (any net, an ITN, or an LLIN), the average number of nets per household, and the percentage of households with at least one net for every two people who slept in the household the previous night.

Sixty-five percent of households in Kenya own at least one mosquito net of any type, 59 percent own at least one ITN, and 57 percent own at least one LLIN. Thirty-four percent of households have reached universal coverage; that is, these households have at least one ITN for every two persons who

[2] This differs slightly from the international definition, which includes nets that have been soaked with insecticide within the past 12 months.

stayed in the household the night before the survey. Household ownership of at least one ITN has improved slightly since the 2008-09 KDHS (56 percent) and the 2010 Kenya Malaria Indicator Survey (KMIS) (48 percent) to the current level of 59 percent.

Slightly more urban households (67 percent) than rural households (64 percent) own at least one mosquito net of any type. However, more rural households (61 percent) than urban households (56 percent) own an ITN. There is marked regional variation in ownership of mosquito nets. The percentage of households that own an ITN is higher in the malaria prone Western (82 percent), Nyanza (81 percent), and Coast (69 percent) regions than in other regions (56 percent or less). As in the 2008-09 KDHS, the 2014 KDHS shows that ownership of at least one ITN is not directly related to household wealth. However, households in the lowest wealth quintile are less likely to own at least one ITN (51 percent) than households in the other wealth quintiles.

Table 12.1 Household possession of mosquito nets

Percentage of households with at least one mosquito net (treated or untreated), insecticide-treated net (ITN), and long-lasting insecticidal net (LLIN); average number of nets, ITNs, and LLINs per household; and percentage of households with at least one net, ITN, and LLIN per two persons[1] who stayed in the household last night, by background characteristics, Kenya 2014

[1] De facto household members
[2] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN) or (2) a net that has been soaked with insecticide within the past six months.

Overall, the average number of ITNs per household is 1.1. The average number of ITNs per household is highest in the Western (1.8) and Nyanza (1.6) regions.

Table 12.1C shows that households in counties in the lakeside endemic zones (Nyanza and Western) are more likely to own at least one ITN than households in counties in other malaria zones. Ownership of an ITN is highest in the counties of Kisumu (88 percent), Kisii (86 percent), and Nyamira (85 percent) in the Nyanza region, followed by Busia (84 percent), Bungoma (83 percent), and Vihiga (83 percent) in the Western region. ITN ownership is lowest in counties in the low risk or seasonal transmission zone: Nyandarua, Laikipia, Samburu, Nyeri, and Elgeyo Marakwet (each less than 25 percent).

Table 12.1C Household possession of mosquito nets

Percentage of households with at least one mosquito net (treated or untreated), insecticide-treated net (ITN), and long-lasting insecticidal net (LLIN); average number of nets, ITNs, and LLINs per household; and percentage of households with at least one net, ITN, and LLIN per two persons who stayed in the household last night, by county, Kenya 2014

[1] De facto household members
[2] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN) or (2) a net that has been soaked with insecticide within the past six months.
† Counties in which ITNs are distributed in some or all of the sub-counties routinely by the government of Kenya.
‡ Counties in which ITNs are distributed in some or all of the sub-counties by mass net campaigns by the government of Kenya.

12.3 ACCESS TO INSECTICIDE-TREATED NETS

Use of ITNs is one of the most effective measures for preventing malaria. The government of Kenya, with support from several partners, has distributed millions of mosquito nets across the country. In addition, increasing knowledge among the populace of the importance of using mosquito nets has led to increased demand. The 2014 KDHS data can be used to show the proportion of the population that could sleep under an ITN if each ITN in the household were used by up to two people. This population is referred to as having access to an ITN. Coupled with data on actual mosquito net usage, ITN access data provide useful information on the magnitude of the behavioural gap in ITN ownership and use or, in other words, the population with access to an ITN but not using it. If the difference between these indicators is substantial, the malaria programme may need to focus on behaviour change and identify the main drivers of or barriers to ITN use to design an appropriate intervention. This analysis helps ITN programmes determine whether they need to achieve higher ITN coverage, promote ITN use, or both.

Table 12.2 presents the percent distribution of the de facto household population by the number of ITNs the household owns, according to the number of persons who stayed in the household the night before the survey. Slightly more than one-third (37 percent) of the population slept in homes without any ITNs the night before the survey and, therefore, were not able to use an ITN. About 2 in 10 individuals stayed in households that own one ITN (20 percent) or two ITNs (23 percent), and 15 percent of the population slept in homes with three ITNs. Few individuals slept in homes with more than four ITNs (4 percent or less). Overall, 48 percent of the population has access to an ITN. ITN access gradually decreases as household size increases in households with four or more persons. For example, 51 percent of households where two persons slept the night before the survey had access to an ITN, whereas 41 percent of households where more than eight people slept had access to an ITN.

Table 12.2 Access to an insecticide-treated net (ITN)

Percent distribution of the de facto household population by number of ITNs the household owns, according to number of persons who stayed in the household the night before the survey, Kenya 2014

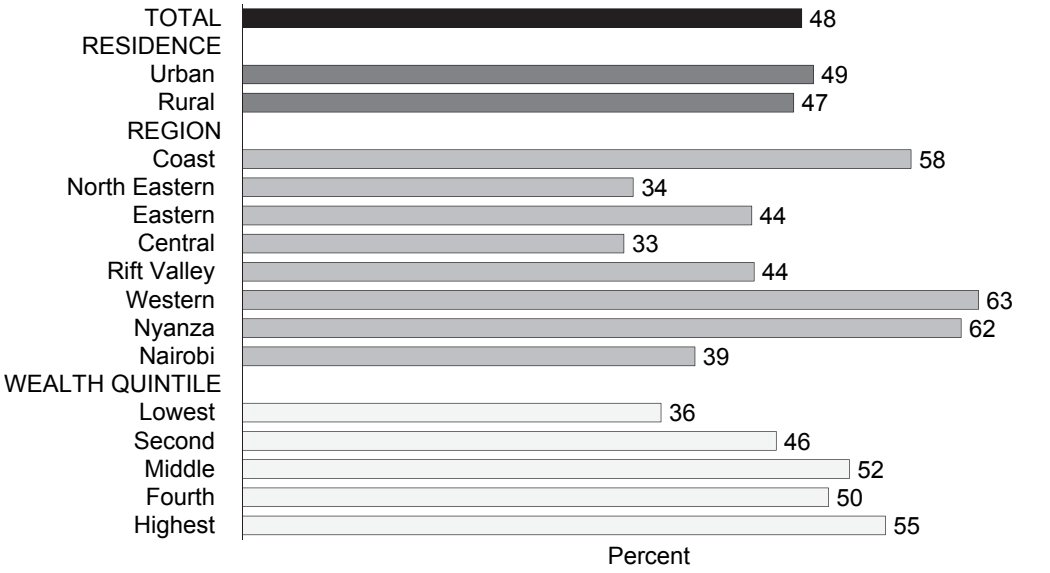
[1] Percentage of the de facto household population who could sleep under an ITN if each ITN in the household were used by up to two people

Figure 12.1 shows the percentage of the de facto population with access to an ITN in the household by residence, region, and wealth quintile. Forty-eight percent of household members in Kenya have access to an ITN. While there is little difference in ITN access between urban and rural areas (49 percent and 47 percent, respectively), there are wide regional variations in ITN access. The majority of household members in Western and Nyanza, within the endemic zones, had access to an ITN (63 percent and 62 percent, respectively). Access to ITNs is lower in Nairobi (39 percent), North Eastern (34 percent), and Central (33 percent). Access to ITNs among household members increases with increasing household wealth, from 36 percent in the lowest wealth quintile to 55 percent in the highest quintile.

Figure 12.1 **Percentage of the de facto population with access to an ITN[1] in the household**



[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a net that has been soaked with insecticide within the past 6 months.

KDHS 2014

12.4 USE OF MOSQUITO NETS

12.4.1 Overall Use of Mosquito Nets

Mosquito net coverage of the entire population is necessary to achieve a large reduction in the malaria burden. Although vulnerable groups, such as children under age 5 and pregnant women, should still be prioritised, the equitable and communal benefits of wide-scale ITN use by older children and adults should be promoted and evaluated by national malaria control programmes (Killeen et al., 2007). The 2014 KDHS asked about use of mosquito nets by household members during the night before the survey.

Table 12.3 presents the percentage of the de facto household population that slept under a mosquito net of any type, under an ITN, or under an LLIN the night before the survey. Two-fifths of the household population (42 percent) slept under an ITN the night prior to the survey. Two-thirds (67 percent) of members of households with at least one ITN slept under an ITN the night prior to the survey.

A higher percentage of women (45 percent) than men (40 percent) slept under an ITN the night prior to the survey. Urban residents (46 percent) are more likely to sleep under an ITN than those in rural areas (41 percent). The Nyanza region (61 percent) has the highest percentage of the household population that slept under an ITN the night prior to the survey, and the Central region (27 percent) has the lowest percentage. The percentage of the household population that slept under an ITN on the night before the survey generally increases with increasing wealth.

Net usage among the population that owns at least one ITN (the final two columns of Table 12.3) is greater than that of the general population, indicating that ITN ownership increases the likelihood of net usage. Variations in ITN use among households that own at least one ITN are similar to those within the general population, with the exception that Nairobi had the highest prevalence of ITN use (78 percent).

Table 12.3 Use of mosquito nets by persons in the household

Percentage of the de facto household population who slept the night before the survey under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), and under a long-lasting insecticidal net (LLIN); and among the de facto household population in households with at least one ITN, the percentage who slept under an ITN the night before the survey, by background characteristics, Kenya 2014

[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a net that has been soaked with insecticide within the past six months.

Table 12.3C presents use of mosquito nets by the household population across counties. The percentage of people who slept under an ITN the night prior to the survey ranges from 5 percent in Nyandarua to 71 percent in Kisii. Generally, individuals in the at-risk counties in Western, Nyanza, and Coast are more likely to have slept under an ITN the night before the survey than those in other counties or regions.

Table 12.3C Use of mosquito nets by persons in the household

Percentage of the de facto household population who slept the night before the survey under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), and under a long-lasting insecticidal net (LLIN); and among the de facto household population in households with at least one ITN, the percentage who slept under an ITN the night before the survey, by county, Kenya 2014

[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a net that has been soaked with insecticide within the past six months.

Table 12.4 presents the percentage of ITNs used in the household by anyone the night before the survey, by background characteristics. Overall, 77 percent of ITNs were used by anyone in the household the night before the survey. Net use was higher in urban areas (80 percent) than in rural areas (76 percent). Net use is lowest in Rift Valley (69 percent) and highest in Nairobi (86 percent), Nyanza (85 percent), and North Eastern (85 percent). This finding is interesting given that Nairobi and North Eastern are in areas of decreased risk. Households in the lowest wealth quintile are least likely to use existing ITNs (71 percent).

Table 12.4C shows that use of existing ITNs by county ranges from 44 percent in Turkana to 92 percent in Mandera. The counties in the coastal and lakeside endemic zones report higher use of existing ITNs; coastal county rates range from 73 percent in Tana River to 86 percent in Kilifi, and lakeside county rates range from 72 percent in Kakamega to 88 percent in Nyamira.

[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a net that has been soaked with insecticide within the past six months.

Figure 12.2 presents data on ownership of, access to, and use of ITNs. Although more than half of households own at least one ITN (59 percent), only one-third (34 percent) own at least one ITN for every two persons. Forty-eight percent of the household population has access to an ITN, and 42 percent slept under an ITN.

KDHS 2014

12.4.2 Use of Mosquito Nets by Children Under Age 5

Use of mosquito nets by vulnerable groups in highly endemic communities is one of the major malaria control and prevention strategies adopted under the National Malaria Strategy (MOH, 2015). Young children are especially vulnerable to malaria. For about six months following birth, antibodies acquired from the mother during pregnancy protect children born in areas of endemic malaria. This immunity is gradually lost, and children start to develop their own immunity to malaria. The pace at which immunity is developed depends on their exposure to malaria infection, and, in highly malaria endemic areas, children are thought to have attained a high level of immunity by their fifth birthday. Such children may experience episodes of malaria illness but usually do not suffer from severe, life-threatening malaria. Immunity in areas of low malaria transmission is acquired more slowly, and malaria illness affects all age groups of the population.

Table 12.5 shows that 54 percent of children under age 5 slept under an ITN the night before the survey. Children in urban areas are more likely to sleep under an ITN (59 percent) than those in rural areas (52 percent). In households overall, children in Nyanza and Western (69 percent) are more likely to sleep under an ITN than children in other regions; however, in households that own at least one ITN, the percentage of children in Nairobi, Coast, and Central (81-86 percent) who slept under an ITN the night before the survey is equivalent to or higher than the percentage of children in the at-risk areas of Western and Nyanza (79 percent and 81 percent, respectively). The percentage of children who slept under an ITN the night before the survey increases with increasing wealth.

Use of mosquito nets among children under age 5 by county is presented in Table 12.5C. The percentage of children under age 5 who slept under an ITN the night before the survey ranges from 12 percent in Marsabit and Nyandarau to 82 percent in Taita Taveta and Kisumu. As expected, more children sleep under an ITN in the counties in the lakeside and coastal endemic zones.

Table 12.5 Use of mosquito nets by children

Percentage of children under five years of age who, the night before the survey, slept under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), and under a long-lasting insecticidal net (LLIN); and among children under five years of age in households with at least one ITN, the percentage who slept under an ITN the night before the survey, by background characteristics, Kenya 2014

[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a net that has been soaked with insecticide within the past six months.

12.4.3 Use of Mosquito Nets by Pregnant Women

In malaria endemic areas, adults usually have acquired some degree of immunity to severe, life-threatening malaria. However, pregnancy leads to depression of the immune system, and thus pregnant women, especially those in their first pregnancy, have a higher risk of malaria. Moreover, these infections may be asymptomatic, may lead to malaria-induced anaemia, and may interfere with the mother-foetus exchange, resulting in low birth weight births. During pregnancy, women can reduce their risk of adverse malaria effects by sleeping under ITNs. Accordingly, the goal of the National Malaria Strategy is for 80 percent of pregnant women to sleep under an ITN (MOH, 2015).

Table 12.6 shows that 51 percent of pregnant women age 15-49 slept under an ITN the night before the survey. Although there is almost no urban-rural difference, there are variations by region; pregnant women in the malaria prone Nyanza (71 percent), Western (67 percent), and Coast (63 percent) regions are more likely to have slept under an ITN than pregnant women in other regions (50 percent or less). Pregnant women with no education and those in the lowest wealth quintile were substantially less likely to have slept under an ITN than their more educated or wealthier counterparts. Not surprisingly, pregnant women in households that own at least one ITN are 1.5 times more likely than pregnant women in the general population to have used an ITN (77 percent compared with 51 percent). There are insufficient cases to evaluate these indicators at the county level, so data at this level are not presented.

Table 12.6 Use of mosquito nets by pregnant women

Percentages of pregnant women age 15-49 who, the night before the survey, slept under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), and under a long-lasting insecticidal net (LLIN); and among pregnant women age 15-49 in households with at least one ITN, the percentage who slept under an ITN the night before the survey, by background characteristics, Kenya 2014

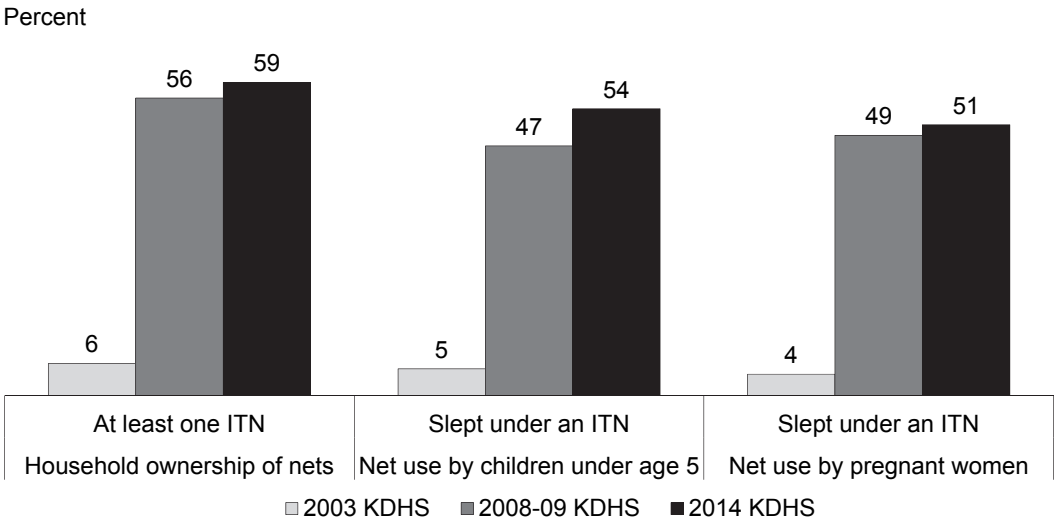
Notes: Table is based on women who stayed in the household the night before the interview. Figures in parentheses are based on 25-49 unweighted cases.
[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a net that has been soaked with insecticide within the past six months.

Figure 12.3 shows that ownership and use of mosquito nets have increased in the last decade, with the largest changes from 2003 to 2008-09. The percentage of households that own at least one ITN increased from 6 percent in 2003 to 59 percent in 2014. The proportion of children under age 5 who slept under an ITN increased from 5 percent to 54 percent, and the percentage of pregnant women age 15-49 who slept under an ITN increased from 4 percent to 51 percent. It is important to note that the timing of data collection can affect net use indicators, since fieldwork for the three surveys may or may not have included the full malaria season.

Figure 12.3 **Trends in ITN[1] ownership and use**



[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a net that has been soaked with insecticide within the past six months.

12.5 PREVENTIVE MALARIA TREATMENT DURING PREGNANCY

Intermittent preventive treatment during pregnancy (IPTp), an important component of malaria control, is intended to reduce malaria during pregnancy. The government of Kenya's IPTp policy states that all pregnant women living in malaria endemic areas should receive at least two doses of sulfadoxine-pyrimethamine (SP), an effective antimalarial drug, during routine antenatal care (ANC) visits. Areas outside of endemic zones do not implement IPTp (MOH, 2010). The first dose of SP should be given at 16 weeks of gestation, and subsequent doses should be administered at each ANC visit, a minimum of one month later (MOH, 2014).

In the 2014 KDHS, women who had a live birth in the two years preceding the survey were asked if they had taken any drugs to prevent them from getting malaria during the pregnancy for their most recent birth and, if so, which drugs. If the respondent did not know the name of the drug she took, interviewers were instructed to show her some examples of common antimalarials. If respondents had taken SP or Fansidar, they were further asked how many times they had taken it and whether they had received it during an antenatal care visit.

Table 12.7 shows the percentage of women who took various doses of SP/Fansidar, at least one during an ANC visit, by background characteristics. Nationally, 17 percent of women took the recommended two or more doses of SP/Fansidar, with at least one dose being administered during an ANC visit. This is a slight increase from 15 percent in the 2008-09 KDHS. Only 10 percent received three or more doses, with at least one dose being administered during an ANC visit. Table 12.7C presents these data by county, with attention given to areas where the government of Kenya implements IPTp. Specifically within these endemic focus areas, 39 percent of women received the recommended two or more doses.

Table 12.7 indicates that rural women are slightly more likely to receive SP/Fansidar during ANC than their urban counterparts. Eighteen percent of rural women received the recommended two or more doses, as compared with 14 percent of urban women. Receipt of two or more doses is not clearly associated with education or wealth at the national level.

Table 12.7 Use of Intermittent Preventive Treatment (IPTp) by women during pregnancy

Percentage of women age 15-49 with a live birth in the two years preceding the survey who, during the pregnancy preceding the last birth, received one or more doses of SP/Fansidar at least one of which was received during an ANC visit, received two or more doses of SP/Fansidar at least one of which was received during an ANC visit, and received three or more doses of SP/Fansidar at least one of which was received during an ANC visit, by background characteristics, Kenya 2014

[1] Received the specified number of doses of SP/Fansidar, at least one of which was received during an ANC visit

Table 12.7C shows that the areas in which the government of Kenya implements IPTp, in fact, report higher rates of IPTp than other areas. More than half of women with a live birth in the preceding two years received the recommended IPTp dosage in the Coast region (53 percent). Thirty-eight percent received two or more doses in Western, and 25 percent received two or more doses in Nyanza's focus counties. In the areas of IPTp implementation, more than half of women in Kwale (79 percent), Lamu (60 percent), and Taita Taveta (55 percent) received two or more doses. Less than one-quarter of women are receiving the recommended doses in Siaya and Homa Bay (both 23 percent).

12.6 FEVER AMONG CHILDREN UNDER AGE 5

The Kenya Malaria Strategy stipulates that, by 2018, 100 percent of all suspected malaria cases presented to a health care provider will be managed according to the National Malaria Treatment Guidelines (MOH, 2015a). According to these guidelines, the first line of treatment is artemisinin combination therapy (ACT) with artemether-lumefantrine (AL).[3] Following reported drug resistance to sulfadoxine-pyrimethamine (SP), the government of Kenya in 2006 rolled out the use of ACT/AL. The treatment guidelines further state that, before treatment is given, the patient should undergo testing either by a rapid diagnostic test or microscopy, so that only patients who have a positive malaria test receive malaria medication (MOH, 2014).

12.6.1 Prevalence and Treatment of Fever among Children

The 2014 KDHS asked mothers whether their children under age 5 had a fever in the two weeks preceding the survey and, if so, whether any treatment was sought. Questions were also asked about blood testing, the types of drugs given to the child, and how soon drugs were taken after onset of fever. Table 12.8 shows the percentage of children under age 5 who had a fever in the two weeks preceding the survey and, among these children, the percentage for whom advice or treatment was sought from a health facility, provider, or pharmacy; the percentage who had a drop of blood taken from a finger or heel prick (considered a proxy for malaria testing); the percentage who received antimalarial treatment; and the percentage receiving treatment the same or the next day.

Twenty-four percent of children under age 5 had a fever in the two weeks preceding the survey. Children age 12-23 months (30 percent), children in rural areas (26 percent), and children in Nyanza (37 percent) and Western (36 percent) were more likely to have suffered fever.

Among children with a fever, 72 percent were taken for advice or treatment, and 35 percent had blood taken from a finger or heel for testing. There do not appear to be differences in blood testing by age, sex, or rural-urban residency. By region, the proportion of children who had blood tested ranged from a high of 47 percent in Nyanza, a region with some malaria endemicity, to a low of 25 percent in Central. In Western and Coast, also malaria prone regions, 38 percent and 35 percent of children with a fever, respectively, had blood drawn for testing. Children whose mothers have a secondary or higher education (38 percent) and those in the highest wealth quintile (44 percent) were most likely to have blood drawn.

Twenty-seven percent of children under age 5 who had a fever took antimalarial drugs, and only 16 percent took antimalarials the same or next day. This is a slight increase from the 2008-09 KDHS, when 23 percent of children with a fever took antimalarials and 12 percent took them within the recommended time frame. Twenty-three percent of children took ACT, and 13 percent took ACT the same or the next day, an increase from 2008-09 (8 percent and 4 percent, respectively). Children in the malaria prone Western and Nyanza regions (28 percent and 25 percent, respectively) were substantially more likely to take ACT the same or the next day than those in other regions (6 percent or less). Children whose mothers have no education were less likely to take antimalarials or ACT and to take them promptly than were children whose mothers have some education. Children in the highest wealth quintile were least likely to take antimalarials or ACT and to take them promptly.

[3] ACT/AL is considered the first line of treatment for uncomplicated malaria. At the time of the 2014 KDHS, a policy change occurred for treatment of severe cases of malaria from quinine to parenteral artesunate, data for which were not collected in the survey.

Table 12.8 Prevalence, diagnosis, and prompt treatment of children with fever

Percentage of children under age five with fever in the two weeks preceding the survey; and among children under age five with fever, the percentage for whom advice or treatment was sought, the percentage who had blood taken from a finger or heel, the percentage who took any artemisinin-based combination therapy (ACT), the percentage who took ACT the same or next day following the onset of fever, the percentage who took antimalarial drugs, and the percentage who took the drugs the same or next day following the onset of fever, by background characteristics, Kenya 2014

Table 12.8C shows the prevalence, diagnosis, and prompt treatment of children with a fever by county. The percentage of children with a fever ranged from 5 percent in Mandera to 49 percent in Vihiga. Among counties with sufficient cases of fever for evaluation, children with a fever in Mombasa (91 percent) were most likely to be taken for treatment, children in Siaya and Isiolo (both 61 percent) were most likely to have blood taken, and children in Siaya and Busia (59 percent and 60 percent, respectively) were most likely to have taken ACT.

Table 12.8C Prevalence, diagnosis, and prompt treatment of children with fever

[1] Excludes relative/friend and traditional practitioner

Table 12.9 presents information on the source of advice or treatment for children under age 5 with a fever. The first column refers to children with a fever in general and can give a sense of the overall coverage of various sources of advice and treatment. The second column refers to children with a fever for whom advice or treatment was sought; from this column, the relative strength of each of the treatment options can be seen. Treatment was sought from a public sector source for 50 percent of children with a fever, mostly from dispensaries (24 percent), government health centres (15 percent), and government hospitals (12 percent). Twenty-one percent went to a private sector source, mostly private hospitals or clinics (12 percent) and pharmacies (8 percent). The second column, focusing on children with a fever for whom advice or treatment was sought, shows that 69 percent of children went to a public sector source, with most visiting a dispensary (33 percent). Twenty-nine percent went to a private sector source for treatment and advice.

Table 12.9 Source of advice or treatment for children with fever

Percentage of children for whom advice or treatment was sought from specific sources among children under age five with fever in the two weeks preceding the survey and among children under age five with fever in the two weeks preceding the survey for whom advice or treatment was sought, by source, Kenya 2014

Source	Percentage for whom advice or treatment was sought from each source: Among children with fever	Among children with fever for whom advice or treatment was sought
Any public sector source	**50.1**	**69.1**
Government hospital	11.9	16.4
Government health centre	15.2	20.9
Government dispensary	23.7	32.6
Other	0.0	0.0
Any private sector source	**21.2**	**29.2**

Friend/relative	0.2	0.3
Number of children	4,562	3,310

12.6.2 Type and Timing of Antimalarial drugs

Among children under age 5 with a fever in the two weeks prior to the survey who also took antimalarial drugs, information was collected on the type of drugs taken and the timing (same or next day). Table 12.10 shows the type and timing of antimalarial drugs used and the percentage of children who took specific antimalarial drugs the same or next day after developing a fever, by background characteristics.

Among children with a fever who took antimalarial drugs, the majority took ACT (86 percent), the recommended first line of treatment for uncomplicated malaria. This is a substantial increase from 34 percent in 2008-09. Two percent to 4 percent took other antimalarial drugs, which are no longer recommended. There are marginal differences in the percentage of children taking ACT by age, sex, rural-urban residence, and mother's education. Children in the highest wealth quintile were less likely (72 percent) to take ACT than those in the lower wealth quintiles (84 percent or higher). There are insufficient cases of children with a fever in the last two weeks to allow an analysis at the county level.

Table 12.10 Type of antimalarial drugs used

Among children under age five with fever in the two weeks preceding the survey who took any antimalarial medication, the percentage who took specific antimalarial drugs, by background characteristics, Kenya 2014

HIV/AIDS-RELATED KNOWLEDGE, ATTITUDES, AND BEHAVIOUR

13

Lawrence Ikamari, John Wanyungu, James Muttunga, Mercy Khasiani, Abdulkadir Amin Awes

Key Findings

- Awareness of AIDS is universal in Kenya. However, only 56 percent of women and 66 percent of men have comprehensive knowledge about HIV and AIDS prevention and transmission; that is, they know that both condom use and limiting sexual intercourse to one uninfected partner can prevent HIV, they are aware that a healthy-looking person can have HIV, and they reject the two most common local misconceptions about HIV: that HIV can be transmitted by mosquitoes and by sharing food.
- Seventy-two percent of women and 62 percent of men know both that HIV can be transmitted through breastfeeding and that the risk of mother-to-child transmission can be reduced by taking special drugs during pregnancy.
- Among those who had more than one sexual partner in the past 12 months, 40 percent of women and 44 percent of men reported using a condom during their last sexual intercourse.
- Since the 2008-09 KDHS, there has been an increase in the percentage of both women (from 29 percent to 53 percent) and men (from 23 percent to 46 percent) who were tested for HIV in the past 12 months and received their results.
- Sixty-eight percent of women who gave birth in the two years before the survey received HIV counselling during antenatal care. Almost 7 in 10 women (69 percent) were tested for HIV during antenatal care and received the test results and post-test counselling, while 23 percent received results but did not receive post-test counselling.

13.1 INTRODUCTION

Acquired immune deficiency syndrome (AIDS) is caused by the human immunodeficiency virus (HIV), which weakens the immune system and makes the body susceptible to and unable to recover from other opportunistic diseases that can lead to death. The predominant modes of HIV transmission are through sexual contact; mother-to-child transmission, in which the mother passes the virus to her child during pregnancy, delivery, or breastfeeding; use of contaminated blood supplies for transfusions; and injections using contaminated needles or syringes.

The AIDS epidemic in Kenya has been severe and generalised since the mid-1980s. HIV prevalence seems to have stabilised in Kenya at 6 percent, but new HIV infections have been estimated at 88,620 annually (National AIDS Control Council [NACC] and National AIDS and STI Control Programme [NASCOP], 2014). The future course of Kenya's AIDS epidemic depends on a number of factors including levels of HIV- and AIDS-related knowledge among the general population, stigma associated with being HIV positive, risk-behaviour modification, access to quality health care services for sexually transmitted infections (STIs), and provision and uptake of HIV counselling and testing.

The principal objective of this chapter is to establish the extent of relevant knowledge, perceptions, and behaviour at the national level as well as within geographic and socioeconomic subpopulations. Prevention programmes can use these data to target groups most in need of information

and most at risk of HIV infection. In this chapter, information on indicators related to HIV and AIDS knowledge, attitudes, and behaviour is presented for the general adult population age 15-49. The chapter also focuses on HIV and AIDS knowledge and patterns of sexual activity among young people age 15-24, as young adults are the main target of many HIV prevention efforts.

13.2 HIV AND AIDS KNOWLEDGE, TRANSMISSION AND PREVENTION METHODS

13.2.1 Awareness of HIV and AIDS

The 2014 KDHS asked respondents whether they have heard of an illness called AIDS. Those who reported having heard of AIDS were asked other questions about whether and how AIDS can be avoided. Table 13.1 shows the percentage of women and men age 15-49 who have heard of AIDS, by background characteristics. In Kenya, knowledge of AIDS is virtually universal (above 99 percent among both women and men). There is no noticeable variation in awareness by respondents' background characteristics. This is consistent with the 2008-09 KDHS.

Table 13.1 Knowledge of AIDS

Percentage of women and men age 15-49 who have heard of AIDS, by background characteristics, Kenya 2014

Table 13.1C shows county-level data on the percentage of women and men age 15-49 who have heard of AIDS. Awareness of AIDS is very high in all counties. However, awareness among women is slightly lower in Wajir (92 percent), Mandera, and West Pokot (both 95 percent); among men, there are no apparent county-level differences.

13.2.2 Knowledge of HIV Prevention Methods

Among adults, HIV is mainly transmitted through sexual contact between an infected partner and an uninfected partner. Accordingly, Kenya's HIV prevention programmes focus on three aspects of behaviour: consistent condom use during sexual intercourse, limiting the number of sexual partners or staying faithful to one partner, and sexual abstinence. In the 2014 KDHS, men and women age 15-49 were asked if it is possible to reduce the risk of acquiring HIV through these three prevention methods. Knowledge of each of the methods is presented in Tables 13.2, 13.2C, and 13.3.

Table 13.2 Knowledge of HIV prevention methods: condom use and limiting sexual partners

Percentage of women and men age 15-49 who, in response to prompted questions, say that people can reduce the risk of getting the AIDS virus by using condoms every time they have sexual intercourse, and by having one sex partner who is not infected and has no other partners, by background characteristics, Kenya 2014

	Women				Men

[1] Using condoms every time they have sexual intercourse
[2] Partner who has no other partners

Table 13.2 shows that knowledge about condom use and limiting sexual partners as methods of avoiding HIV transmission is generally high and widespread. Eighty percent of women and 88 percent of men know that the risk of getting HIV can be reduced by using condoms. Ninety-two percent of women and 94 percent of men know that limiting sexual intercourse to one uninfected partner can reduce the chances of contracting HIV. Seventy-seven percent of women and 85 percent of men are aware of both of these prevention methods. Young women and men age 15-19 (67 percent and 77 percent, respectively) are least likely among all age groups to be aware of both prevention methods.

As in the 2008-09 KDHS, women and men who have never had sex (64 percent and 73 percent, respectively) and those in rural areas (74 percent and 82 percent, respectively) have less knowledge of HIV prevention methods than their counterparts. Knowledge of HIV prevention methods varies by region and is lowest in North Eastern (women, 21 percent; men, 48 percent) and highest in Nyanza (women, 85 percent; men, 93 percent). Knowledge of condom use and limiting sexual partners as methods of HIV prevention increases with increasing education and wealth among both women and men.

Table 13.2C Knowledge of HIV prevention methods by county: condom use and limiting sexual partners

Percentage of women and men age 15-49 who, in response to prompted questions, say that people can reduce the risk of getting the AIDS virus by using condoms every time they have sexual intercourse, and by having one sex partner who is not infected and has no other partners, by county, Kenya 2014

[1] Using condoms every time they have sexual intercourse
[2] Partner who has no other partners

Table 13.2C presents information by county about knowledge of condom use and limiting sexual partners as methods of HIV prevention. The results show that there is variation across counties in women's and men's knowledge. Women in Garissa, Wajir, and Mandera (below 60 percent) and men in Turkana and Wajir (below 40 percent) have the least knowledge of these two HIV prevention methods.

Table 13.3 presents the percentage of women and men age 15-49 who say that abstinence can reduce the risk of HIV, by background characteristics. Eighty-four percent of women and 88 percent of men know that abstaining from sex can reduce the risk of getting HIV. Women and men who have never had sex are less likely to know that abstinence is an effective way to reduce the risk of contracting HIV (78 percent and 84 percent, respectively), as are women and men in the North Eastern region (43 percent and 64 percent, respectively). In general, knowledge of this HIV prevention method increases with increasing education and wealth.

Table 13.3 Knowledge of HIV prevention methods: abstinence

Percentage of women and men age 15-49 who, in response to prompted questions, say that people can reduce the risk of getting the AIDS virus by abstaining from sexual intercourse, by background characteristics, Kenya 2014

	Women		Men

Figures 13.1 and 13.2 show that both women's and men's knowledge of using condoms and limiting sex as methods of HIV prevention increased from 2003 to 2014. Across time, men have consistently reported higher levels of knowledge of HIV prevention methods than women.

Figure 13.1 **Trends in knowledge of HIV prevention methods: Women**

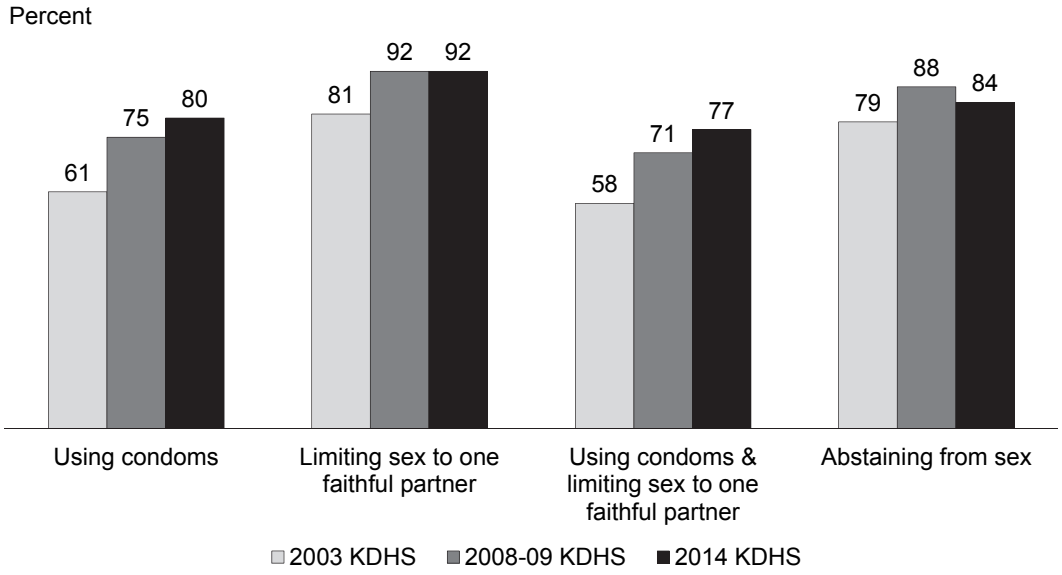

Figure 13.2 **Trends in knowledge of HIV prevention methods: Men**

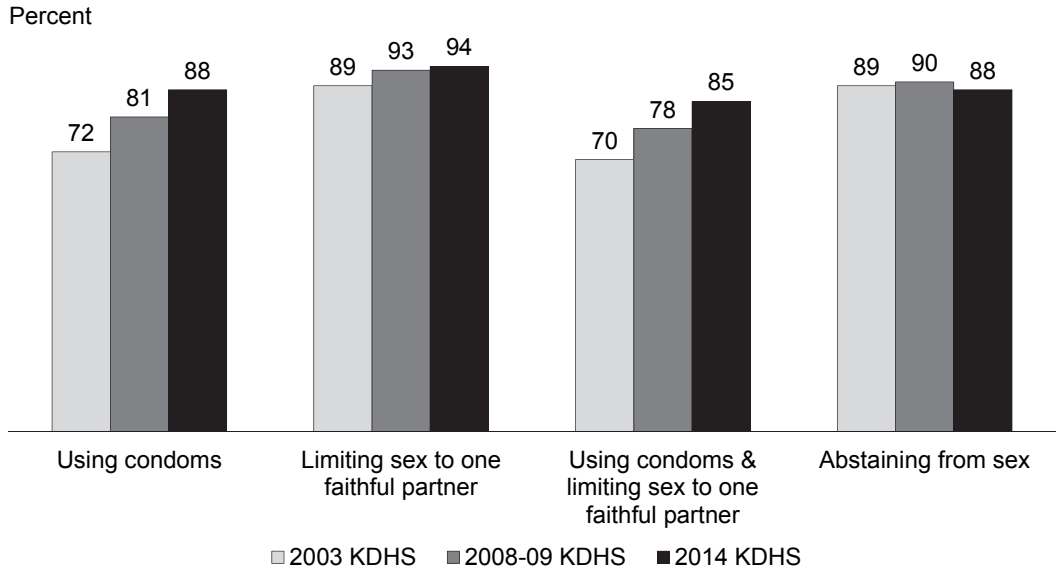

13.2.3 Rejection of Misconceptions about HIV/AIDS

As part of the effort to assess HIV and AIDS knowledge, the 2014 KDHS investigated the prevalence of common misconceptions about HIV transmission. Respondents were asked whether it is possible for a healthy-looking person to have HIV and whether HIV is transmitted through mosquito bites, supernatural means, or sharing food with a person who has HIV or AIDS. Results are presented in Tables 13.4.1 and 13.4.2 by background characteristics.

Table 13.4.1 Comprehensive knowledge about AIDS: Women

Percentage of women age 15-49 who say that a healthy-looking person can have the AIDS virus and who, in response to prompted questions, correctly reject local misconceptions about transmission or prevention of the AIDS virus, and the percentage with a comprehensive knowledge about AIDS by background characteristics, Kenya 2014

Background characteristic	Percentage of respondents who say that:				Percentage who say that a healthy looking person can have the AIDS virus and who reject the two most common local misconceptions[1]	Percentage with a comprehensive knowledge about AIDS[2]	Number of women
	A healthy-looking person can have the AIDS virus	The AIDS virus cannot be transmitted by mosquito bites	The AIDS virus cannot be transmitted by supernatural means	A person cannot become infected by sharing food with a person who has the AIDS

[1] Two most common local misconceptions of source of disease: mosquito bites and sharing food with a person who has AIDS.
[2] Comprehensive knowledge means knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting the AIDS virus, knowing that a healthy-looking person can have the AIDS virus, and rejecting the two most common local misconceptions about AIDS transmission or prevention.

The data indicate that some misconceptions regarding how AIDS is transmitted still exist in Kenya. It is encouraging that about 9 in 10 women and men know that a healthy-looking person can have the AIDS virus and know that AIDS cannot be transmitted by supernatural means or by sharing food with a person who has AIDS. However, misunderstandings about transmission through insects are slightly more widespread; about 8 in 10 respondents know that AIDS cannot be transmitted by mosquito bites.

Comprehensive knowledge about HIV is a composite measure defined as knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chance of contracting HIV, knowing that a healthy-looking person can have HIV, knowing that HIV cannot be transmitted by mosquito bites, and knowing that HIV cannot be contracted by sharing food with a person who has AIDS. Fifty-six percent of women and 66 percent of men have comprehensive knowledge about HIV and AIDS. This is a slight increase since the 2008-09 KDHS, where comprehensive knowledge was 48 percent among women and 55 percent among men.

Table 13.4.2 Comprehensive knowledge about AIDS: Men

Percentage of men age 15-49 who say that a healthy-looking person can have the AIDS virus and who, in response to prompted questions, correctly reject local misconceptions about transmission or prevention of the AIDS virus, and the percentage with a comprehensive knowledge about AIDS by background characteristics, Kenya 2014

Background characteristic	Percentage of respondents who say that:				Percentage who say that a healthy looking person can have the AIDS virus and who reject the two most common local misconceptions[1]	Percentage with a comprehensive knowledge about AIDS[2]	Number of men
	A healthy-looking person can have the AIDS virus	The AIDS virus cannot be transmitted by mosquito bites	The AIDS virus cannot be transmitted by supernatural means	A person cannot become infected by sharing food with a person who has the AIDS

[1] Two most common local misconceptions of source of disease: mosquito bites and sharing food with a person who has AIDS.
[2] Comprehensive knowledge means knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting the AIDS virus, knowing that a healthy-looking person can have the AIDS virus, and rejecting the two most common local misconceptions about AIDS transmission or prevention.

Women with the highest comprehensive knowledge of AIDS are found in Nyamira (89 percent), Nandi (78 percent), and Kisii (71 percent) counties (Table 13.4.1C). Women in Mandera (4 percent), Wajir (8 percent), and Garissa (19 percent) are least likely to have comprehensive knowledge. Comprehensive knowledge among men is highest in Nandi (93 percent), Nyamira (91 percent), and Kiambu (85 percent) and lowest in Turkana (2 percent), Mandera (4 percent), and Wajir (9 percent) (Table 13.4.2C).

Table 13.4.1C Comprehensive knowledge about AIDS: Women

[1] Two most common local misconceptions of source of disease: mosquito bites and sharing food with a person who has AIDS.
[2] Comprehensive knowledge means knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting the AIDS virus, knowing that a healthy-looking person can have the AIDS virus, and rejecting the two most common local misconceptions about AIDS transmission or prevention.

13.2.4 Knowledge of Mother-to-Child Transmission of HIV

Increasing the level of general knowledge of how HIV is transmitted from mother to child and reducing the risk of transmission by using antiretroviral drugs is critical to reducing mother-to-child transmission of HIV (MTCT). To assess MTCT knowledge, respondents were asked whether HIV can be transmitted from a mother to a child through breastfeeding and whether a mother with HIV can reduce the risk of transmission to her baby by taking special drugs during pregnancy.

Table 13.5 shows MTCT knowledge among women and men age 15-49 by background characteristics. Eighty-nine percent of women and 87 percent of men know that HIV can be transmitted through breastfeeding, and 76 percent of women and 68 percent of men know that the risk of MTCT

Table 13.5 Knowledge of prevention of mother to child transmission of HIV

Percentage of women and men age 15-49 who know that HIV can be transmitted from mother to child by breastfeeding and that the risk of mother to child transmission (MTCT) of HIV can be reduced by mother taking special drugs during pregnancy, by background characteristics, Kenya 2014

	Percentage of women who know that:				Percentage of men who know that:			
Background characteristic	HIV can be transmitted by breastfeeding	Risk of MTCT can be reduced by mother taking special drugs during pregnancy	HIV can be transmitted by breastfeeding and risk of MTCT can be reduced by mother taking special drugs during pregnancy	Number of women	HIV can be transmitted by breastfeeding	Risk of MTCT can be reduced by mother taking special drugs during pregnancy	HIV can be transmitted by breastfeeding and risk of MTCT can be reduced by mother taking special drugs during pregnancy	Number of men

can be reduced by the mother taking special drugs during pregnancy. Seventy-two percent of women and 62 percent of men know both that HIV can be transmitted through breastfeeding and that the risk of MTCT can be reduced by taking special drugs during pregnancy. There has been a slight increase in knowledge about HIV transmission through breastfeeding and MTCT-reducing drugs since 2008-09.

Knowledge of HIV transmission through breastfeeding and of MTCT-reducing drugs is lowest among women and men who are age 15-19 (59 percent and 50 percent, respectively), who have never had sex (57 percent and 49 percent, respectively), and who live in North Eastern region (31 percent and 50 percent, respectively). Among both women and men, knowledge of transmission through breastfeeding and MTCT-reducing drugs increases with increasing education and wealth.

Table 13.5C shows that there is some variation in MTCT knowledge across counties. Among women, the level of knowledge is highest in Bungoma (87 percent) and in Kilifi, Kitui, and Nandi counties (86 percent each) and lowest in Wajir and Marsabit (29 percent each). Among men, the highest level of knowledge is found in Mombasa (85 percent) and Machakos (84 percent) and the lowest in Wajir and West Pokot (18 percent each).

Table 13.5C Knowledge of prevention of mother to child transmission of HIV

Percentage of women and men age 15-49 who know that HIV can be transmitted from mother to child by breastfeeding and that the risk of mother to child transmission (MTCT) of HIV can be reduced by mother taking special drugs during pregnancy, by county, Kenya 2014

13.3 ATTITUDES TOWARDS PEOPLE LIVING WITH HIV AND AIDS

Widespread stigma and discrimination against those living with HIV and AIDS can adversely affect people's willingness to be tested and their adherence to antiretroviral therapy. Survey respondents who had heard of AIDS were asked if they would be willing to care for a family member with AIDS in their own household, if they would buy fresh vegetables from a shopkeeper who has the AIDS virus, if they thought a female teacher who has the AIDS virus but is not sick should be allowed to continue teaching, and if they would like to keep a family member's positive HIV status secret. Table 13.6.1 and Figure 13.3 show the results for women age 15-49 by background characteristics, and Table 13.6.2 and Figure 13.4 show the results for men.

Table 13.6.1 Accepting attitudes towards those living with HIV/AIDS: Women

Among women age 15-49 who have heard of AIDS, percentage expressing specific accepting attitudes towards people with HIV/AIDS, by background characteristics, Kenya 2014

	Percentage of women who:					
Background characteristic	Are willing to care for a family member with AIDS in the respondent's home	Would buy fresh vegetables from shopkeeper who has the AIDS virus	Say that a female teacher who has the AIDS virus but is not sick should be allowed to continue teaching	Would not want to keep secret that a family member got infected with the AIDS virus	Percentage expressing accepting attitudes on all four indicators	Number of women who have heard of AIDS
Age						
15-24	91.6	75.7	88.1	33.3	23.0	5,385

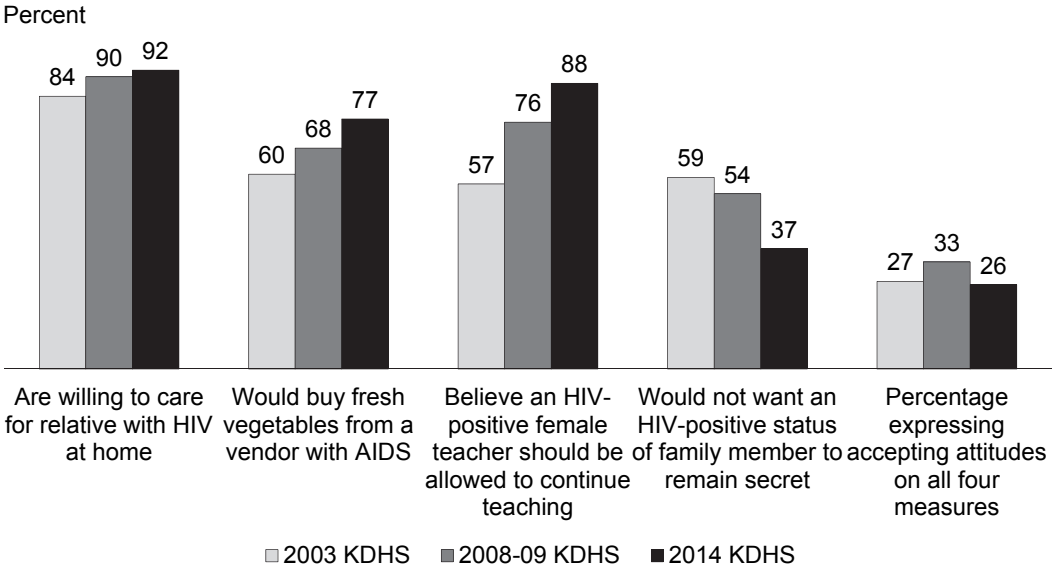
Ninety-two percent of women and 95 percent of men reported that they would be willing to care for a relative sick with HIV, 77 percent of women and 84 percent of men said that they would be willing to buy fresh vegetables from a vendor who has AIDS, and 88 percent of both women and men agreed that a female teacher who has the AIDS virus but is not sick should be allowed to continue teaching. Since 2003, there has been continuous improvement in these three measures of accepting attitudes.

Figure 13.3 **Accepting attitudes towards those with HIV: Women**



The proportion of respondents with accepting attitudes related to disclosure of a family member's HIV-positive status continues to decline, however. In 2014, 37 percent of women and 55 percent of men reported that if a family member became infected with the HIV virus, they would not want it to remain secret, a decrease from 54 percent of women and 69 percent of men in 2008-09 and 59 percent of women and 72 percent of men in 2003.

The percentage of women and men expressing accepting attitudes on all four measures remains low. Only one in four women (26 percent) and two in five men (44 percent) show acceptance on all four measures, a decrease from the figures reported in 2008-09 (33 percent among women and 48 percent among men).

Urban women (30 percent) are more likely than rural women (23 percent) to have accepting attitudes on all four measures; the difference between urban and rural men is minimal. Accepting attitudes remain lowest in the North Eastern region; only 3 percent of women and 31 percent of men currently express accepting attitudes on all four measures. In 2008-09, a similarly low 11 percent of women and 14 percent of men in that region expressed acceptance.

Table 13.6.2 Accepting attitudes towards those living with HIV/AIDS: Men

Among men age 15-49 who have heard of HIV/AIDS, percentage expressing specific accepting attitudes towards people with HIV/AIDS, by background characteristics, Kenya 2014

Background characteristic	Percentage of men who: Are willing to care for a family member with AIDS in the respondent's home	Would buy fresh vegetables from shopkeeper who has the AIDS virus	Say that a female teacher who has the AIDS virus but is not sick should be allowed to continue teaching	Would not want to keep secret that a family member got infected with the AIDS virus	Percentage expressing accepting attitudes on all four indicators	Number of men who have heard of AIDS

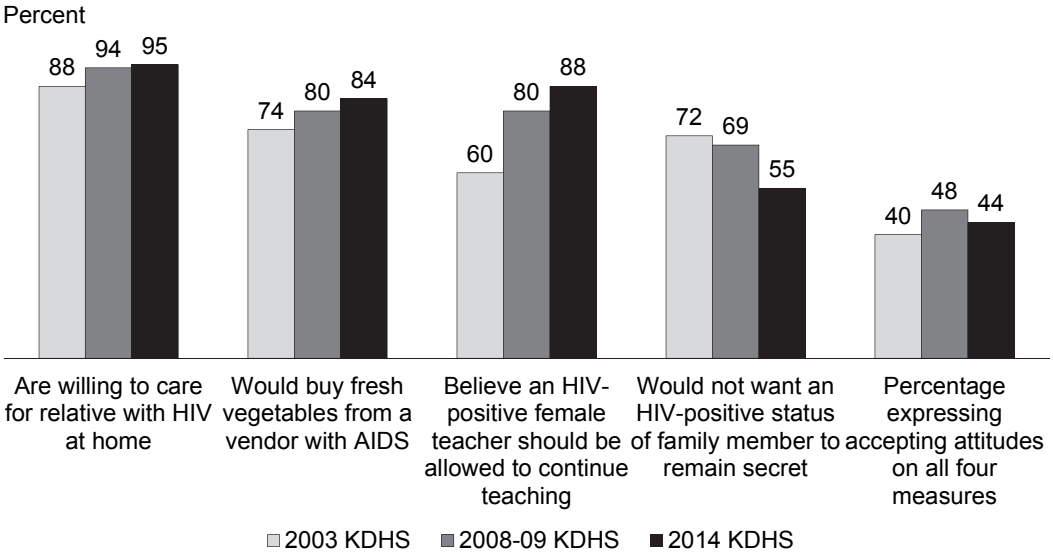
Education and socioeconomic status remain strongly related to positive attitudes towards those who are HIV positive. The proportion of women and men who express accepting attitudes on all four measures increases with increasing education as well as wealth. Only 7 percent of women and 18 percent of men with no education express acceptance on all four measures, as compared with 33 percent of women and 50 percent of men with a secondary or higher education. Similarly, women in the highest wealth quintile are more than twice as likely to express accepting attitudes on all four measures as those in the lowest quintile (33 percent versus 13 percent). Forty-seven percent of men in the highest wealth quintile express accepting attitudes on all four measures, compared to 31 percent of those in the lowest quintile.

Figure 13.4 **Accepting attitudes towards those with HIV: Men**



13.4 ATTITUDES TOWARDS NEGOTIATING SAFER SEXUAL RELATIONSHIPS

HIV transmission in Kenya mainly occurs through sexual intercourse. Safer sex is an important prevention strategy and can reduce individuals' risk of contracting HIV. Negotiating safer sex can be difficult, especially for married women. Table 13.7 shows the percentage of women and men age 15-49 who believe that a woman is justified in refusing to have sex with her husband if he has sex with other women or in asking that her husband use a condom if she knows he has an STI.

Seventy-nine percent of both women and men believe that a wife is justified in refusing to have sexual intercourse with her husband if he has sex with other women. Higher proportions of women (89 percent) and men (92 percent) believe that a wife is justified in asking her husband/partner to use a condom if she knows he has an STI.

Positive attitudes towards sexual negotiation follow similar patterns to other HIV-related attitudes. They are lowest among women and men age 15-19, women and men who have never had sex, and rural women and men. Women in North Eastern are much less likely than women in other regions to support either refusing sex (32 percent) or asking for condom use (19 percent). Interestingly, men in North Eastern are much more supportive than women in that region (76 percent support refusing sex and 72 percent support asking for condom use). Support for women's right to negotiate safer sex increases with increasing education and wealth among both men and women.

Table 13.7 Attitudes towards negotiating safer sexual relations with husband

Percentage of women and men age 15-49 who believe that a woman is justified in refusing to have sexual intercourse with her husband if she knows that he has sexual intercourse with other women, and percentage who believe that a woman is justified in asking that they use a condom if she knows that her husband has a sexually transmitted infection (STI), by background characteristics, Kenya 2014

	Percentage of women who believe that a woman is justified in:			Percentage of men who believe that a woman is justified in:		
Background characteristic	Refusing to have sexual intercourse with her husband if she knows he has sex with other women	Asking that they use a condom if she knows that her husband has an STI	Number of women	Refusing to have sexual intercourse with her husband if she knows he has sex with other women	Asking that they use a condom if she knows that her husband has an STI	Number of men

13.5 ATTITUDE TOWARDS CONDOM EDUCATION FOR YOUTH

Condom use is one of the most effective strategies for combating the spread of HIV. However, educating youth about condoms is sometimes controversial, with some people believing that it promotes early sexual initiation (MOH, 2015b). To gauge attitudes towards condom education for youth, respondents were asked if they thought that young people age 12-14 should be taught about using condoms to avoid HIV infection. Results are tabulated for adult respondents (those age 18 and above). Table 13.8 shows the percentage of women and men age 18-49 who agree that children age 12-14 should be taught about using a condom to avoid AIDS, by background characteristics.

Table 13.8 Adult support of education about condom use to prevent AIDS

Six in 10 women (58 percent) and men (62 percent) support teaching young people about condoms for HIV prevention. Among men, this is a decline from the 2008-09 KDHS, when 72 percent supported teaching young people about condoms. There is no clear trend in opinions across age or rural-urban residence. More than 70 percent of women and men from the Nyanza and Western regions support youth condom education. Residents of North Eastern are least likely to agree that young people should be taught about condoms (9 percent of women and 14 percent of men).

Women and men with no education are less likely than their more educated counterparts to agree that youth age 12-14 should be taught about condoms. Thirty-nine percent of women with no education support condom education, as compared with 58 percent or more among those at higher educational levels. Similarly, 30 percent of men with no education support condom education, compared with 63 percent or more among those at higher levels of education. Women (51 percent) and men (53 percent) in the lowest wealth quintile are least likely to support condom education.

13.6 HIGH-RISK SEX

Information on sexual behaviour is important in designing and monitoring programmes to control the spread of HIV. The 2014 KDHS included questions on respondents' sexual partners both during their lifetime and over the 12 months preceding the survey. Men were also asked whether they paid for sex during the 12 months preceding the interview. In addition, information was collected on women's and men's use of condoms during their last sexual encounter with each type of partner. These questions are sensitive, and some respondents may have been reluctant to provide information on recent sexual behaviour.

13.6.1 Multiple Partners and Condom Use

Tables 13.9.1 and 13.9.2 show the percentage of women and men age 15-49 who had sexual intercourse with more than one partner in the past 12 months and, among those with more than one partner in the past 12 months, the percentage reporting that a condom was used during their most recent intercourse. Also shown is the mean number of lifetime sexual partners among respondents who had ever had sex. Men are much more likely than women to report having two or more sexual partners in the 12 months before the survey (13 percent and 1 percent, respectively). Among men, those in their 20s (17 percent); those who are divorced, separated, or widowed (19 percent); and those residing in Nairobi (19 percent) and Nyanza (18 percent) are most likely to have had multiple partners in the 12 months preceding the survey. Men in the Central and North Eastern regions are least likely to report multiple partners (both 6 percent). There are no clear patterns by education or wealth.

Forty percent of women and 44 percent of men who had two or more partners in the 12 months preceding the survey reported using a condom during their last sexual intercourse. Among men, this is a decrease from the 62 percent reported in the 2008-09 KDHS. Condom use decreases with age among men and is lowest among those who are married or living together with a partner (20 percent), those in the Western (27 percent) and Coast (32 percent) regions, those with no education (18 percent), and those in the lowest wealth quintile (31 percent).

Among respondents who have ever had sexual intercourse, the mean number of lifetime sexual partners is considerably higher among men (6.8) than among women (2.1). Mean number of partners increases with age among both men and women. For men, the mean number is higher among those who are divorced, separated, or widowed; those in polygynous marriages; and those living in Nairobi.

Table 13.9.1 Multiple sexual partners: Women

Among all women age 15-49, the percentage who had sexual intercourse with more than one sexual partner in the past 12 months; among those having more than one partner in the past 12 months, the percentage reporting that a condom was used at last intercourse; and the mean number of sexual partners during their lifetime for women who ever had sexual intercourse, by background characteristics, Kenya 2014

[1] Means are calculated excluding respondents who gave non-numeric responses.

13.6.2 Point Prevalence and Cumulative Prevalence of Concurrent Sexual Partners

The 2014 KDHS provides information on concurrent relationships by presenting the point prevalence and the cumulative prevalence of concurrent sexual partners. The point prevalence of concurrent sexual partners is defined as the percentage of respondents who had two or more sexual partners concurrently at the point in time six months before the survey. The cumulative prevalence of concurrent sexual partners is defined as the percentage of respondents who had two or more partners concurrently at any time during the 12 months preceding the survey. Table 13.10 shows the point prevalence and cumulative prevalence of concurrent sexual partners among women and men age 15-49 during the 12 months before the survey. It also shows, among women and men who had multiple sexual partners in the 12 months before the survey, the percentage who had concurrent sexual partners.

Table 13.10 Point prevalence and cumulative prevalence of concurrent sexual partners

Percentage of all women and men age 15-49 who had concurrent sexual partners six months before the survey (point prevalence[1]), and percentage of all women and all men age 15-49 who had any concurrent sexual partners during the 12 months before the survey (cumulative prevalence[2]), and among women and men age 15-49 who had multiple sexual partners during the 12 months before the survey, percentage who had concurrent sexual partners, by background characteristics, Kenya 2014

Background characteristic	Among all respondents:			Among all respondents who had multiple partners during the 12 months before the survey:	
	Point prevalence of concurrent sexual partners[1]	Cumulative prevalence of concurrent sexual partners[2]	Number of respondents	Percentage who had concurrent sexual partners[2]	Number of respondents

50-54	8.2	10.7	756	93.6	86
Total 15-54	5.0	9.5	12,819	75.1	1,618

Note: Two sexual partners are considered to be concurrent if the date of the most recent sexual intercourse with the earlier partner is after the date of the first sexual intercourse with the later partner. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed..

[1] The percentage of respondents who had two (or more) sexual partners that were concurrent at the point in time six months before the survey

[2] The percentage of respondents who had two (or more) sexual partners that were concurrent anytime during the 12 months preceding the survey

Among women, both the point prevalence and the cumulative prevalence are less than 1 percent. Among men, the point prevalence is 5 percent and the cumulative prevalence is 9 percent. The point prevalence for men increases with age. The cumulative prevalence is slightly higher among men age 25 to 39 and among men in urban areas. Both the point prevalence and the cumulative prevalence among married men are equal to or higher than those of their non-married counterparts; to some extent, this is attributable to polygamy among married men.

Women with multiple sexual partners in the last 12 months are less likely than men to have concurrent partners (52 percent versus 74 percent). Women who are married (53 percent) and urban women (44 percent) are less likely to have concurrent partners than women who have never been married (63 percent) and those who reside in rural areas (64 percent). The percentage of men with recent concurrent sexual partners increases with age; the percentage is highest among married men (92 percent) and men in polygynous unions (97 percent).

13.6.3 Transactional Sex

Payment for sexual intercourse is associated with risk of contracting HIV and other sexually transmitted infections due to compromised power relations that result in inconsistent condom use. In the 2014 KDHS, men age 15-49 were asked if they had ever paid for sexual intercourse, if they had paid for sexual intercourse in the 12 months preceding the survey, and, among those who had paid for sexual intercourse in the 12 months preceding the survey, whether they used condoms the last time they paid for sexual intercourse.

Table 13.11 shows that 9 percent of men had ever paid for sex and that 3 percent had paid for sex in the 12 months before the survey. Seventy-four percent of men who reported having paid for sex in the 12 months before the survey said that they used a condom the last time they paid for sex.

Men age 30-39 are more likely than their counterparts to have ever paid for sex (13 percent), to have paid for sex in the 12 months before the survey (3 percent), and to have used a condom during their last paid sex (83 percent). A similar pattern prevails among men who are divorced, separated, or widowed (21 percent had ever paid for sex, 8 percent paid in the previous 12 months, and 83 percent used a condom during their last paid sex). Urban men are more likely than rural men to have ever paid for sex (11 percent compared with 7 percent) and to have used a condom during their last paid sex (80 percent compared with 70 percent). Men in the Coast region are most likely to have ever paid for sex (14 percent), and men in the Western and Nyanza regions are most likely to have paid for sex in the previous 12 months (both 4 percent). Men in North Eastern are least likely to report ever having paid for sex (1 percent) or having paid for sex in the previous 12 months (1 percent). There are no apparent trends by education or wealth.

By county, men in Migori (11 percent), Kakamega (6 percent), Vihiga (6 percent), and Elgeyo Marakwet (6 percent) are somewhat more likely to have paid for sex in the previous 12 months than men in other counties (Table 13.11C).

Table 13.11 Payment for sexual intercourse and condom use at last paid sexual intercourse

13.7 COVERAGE OF HIV COUNSELLING AND TESTING

13.7.1 General HIV Testing

HIV counselling and testing is the entry point to HIV prevention, care, and support and treatment services. Knowledge of HIV status helps HIV-negative individuals make decisions that can reduce their risk. For those who are HIV positive, knowledge of their status allows them to take action to protect their sexual partners, to access treatment, and to plan for the future. To assess awareness and coverage of HIV testing services, respondents in the 2014 KDHS were asked if they knew a place where they could go to be tested and further if they have ever undergone an HIV test and received the results of the test.

Tables 13.12.1 and 13.12.2 show, among women and men age 15-49, the percentage who know where to get an HIV test, the percent distribution by testing status and by whether they received their results, the percentage ever tested, and the percentage tested in the 12 months preceding the survey who received the results of their last test, by background characteristics.

Knowledge of a place to get tested for HIV is widespread in Kenya; 91 percent of women and 97 percent of men know a place where people get tested for HIV. Knowledge generally increases with age among both women and men. Relative to their respective counterparts, knowledge is lower among women and men who have never been married and never had sex, women and men in rural areas, and women and men in North Eastern. Among both women and men, knowledge of a place to get tested for HIV generally increases with increasing education and wealth.

There has been a noticeable increase since 2008-09 in the percentage of women and men age 15-49 who have ever been tested: from 58 percent and 42 percent, respectively, to 85 percent and 72 percent. There has also been an increase, albeit less dramatic, in the percentage of women and men who were tested in the past 12 months and received their results: from 29 percent and 23 percent, respectively, to 53 percent and 46 percent. The proportion of women and men who were recently tested and received their results is higher among those who are married or have been married, urban residents, those at higher educational levels, and those who are wealthier.

By county, women in Wajir and Mandera and men in West Pokot and Mandera are least likely to have ever been tested or to have been tested in the past 12 months. The counties with the highest levels of lifetime and recent testing among women include Homa Bay, Uasin Gishu, Migori, and Kisumu, and the counties with the highest levels among men include Migori, Kisumu, and Siaya (Tables 13.12.1C and 13.12.2C).

Table 13.12.1 Coverage of prior HIV testing: Women

Percentage of women age 15-49 who know where to get an HIV test, percent distribution of women age 15-49 by testing status and by whether they received the results of the last test, the percentage of women ever tested, and the percentage of women age 15-49 who were tested in the past 12 months and received the results of the last test, according to background characteristics, Kenya 2014

Background characteristic	Percentage who know where to get an HIV test	Percent distribution of women by testing status and by whether they received the results of the last test			Total	Percentage ever tested	Percentage who have been tested for HIV in the past 12 months and received the results of the last test	Number of women

Table 13.12.2 Coverage of prior HIV testing: Men

Percentage of men age 15-49 who know where to get an HIV test, percent distribution of men age 15-49 by testing status and by whether they received the results of the last test, the percentage of men ever tested, and the percentage of men age 15-49 who were tested in the past 12 months and received the results of the last test, according to background characteristics, Kenya 2014

Background characteristic	Percentage who know where to get an HIV test	Percent distribution of men by testing status and by whether they received the results of the last test			Total	Percentage ever tested	Percentage who have been tested for HIV in the past 12 months and received the results of the last test	Number of men
		Ever tested and received results	Ever tested, did not receive results	Never tested[1]				
Age								
15-24	94.2	56.6	0.9	42.5	100.0	57.5	38.9	4,666

13.7.2 HIV Counselling and Testing During Pregnancy

Table 13.13 presents information on HIV screening of women age 15-49 who gave birth in the two years preceding the survey. The HIV screening process is a key tool in reducing mother-to-child transmission of HIV. Sixty-eight percent of women who gave birth in the two years before the survey received HIV counselling during antenatal care (ANC). Almost 7 in 10 women (69 percent) were tested for HIV during antenatal care and received the test results and post-test counselling, while 23 percent received results but did not receive post-test counselling. Less than 1 percent of women were tested for HIV during an ANC visit but did not receive the test results.

Table 13.13 Pregnant women counselled and tested for HIV

Among all women age 15-49 who gave birth in the two years preceding the survey, the percentage who received HIV pretest counselling, the percentage who received an HIV test during antenatal care for their most recent birth by whether they received their results and post-test counselling, and percentage who received an HIV test at the time during ANC or labour for their most recent birth by whether they received their test results, according to background characteristics, Kenya 2014

Background characteristic	Percentage who received counselling on HIV during antenatal care[1]	Percentage who were tested for HIV during antenatal care and who:			Percentage who received counselling on HIV and an HIV test during ANC, and the results	Percentage who had an HIV test during ANC or labour and who:[2]		Number of women who gave birth in the past two years[3]
		Received results and received post-test counselling	Received results and did not receive post-test counselling	Did not receive results		Received results	Did not receive results

[1] In this context, "pretest counselling" means that someone talked with the respondent about all three of the following topics: 1) babies getting the AIDS virus from their mother, 2) preventing the virus, and 3) getting tested for the virus.
[2] Women are asked whether they received an HIV test during labour only if they were not tested for HIV during ANC.
[3] Denominator for percentages includes women who did not receive antenatal care for their last birth in the past two years.

Table 13.13C Pregnant women counselled and tested for HIV

Among all women age 15-49 who gave birth in the two years preceding the survey, the percentage who received HIV pretest counselling, the percentage who received an HIV test during antenatal care for their most recent birth by whether they received their results and post-test counselling, and percentage who received an HIV test at the time during ANC or labour for their most recent birth by whether they received their test results, according to county, Kenya 2014

County	Percentage who received counselling on HIV during antenatal care[1]	Percentage who were tested for HIV during antenatal care and who:			Percentage who received counselling on HIV and an HIV test during ANC, and the results	Percentage who had an HIV test during ANC or labour and who:[2]		Number of women who gave birth in the past two years[3]
		Received results and received post-test counselling	Received results and did not receive post-test counselling	Did not receive results		Received results	Did not receive results

[1] In this context, "pretest counselling" means that someone talked with the respondent about all three of the following topics: 1) babies getting the AIDS virus from their mother, 2) preventing the virus, and 3) getting tested for the virus
[2] Women are asked whether they received an HIV test during labour only if they were not tested for HIV during ANC
[3] Denominator for percentages includes women who did not receive antenatal care for their last birth in the past two years

Overall, 67 percent of women received HIV counselling, an HIV test, and the results during ANC for their most recent birth in the two years preceding the survey. By age, differences are marginal except for women age 40-49, who were less likely to be counselled, tested, and given their HIV result during ANC than were younger women. Women were more likely to have been counselled and tested and to have received test results if they lived in urban areas (75 percent) or in Nairobi (85 percent). The likelihood of HIV counselling and testing during ANC increases with increasing education and wealth. For example, the proportion of women who were counselled about HIV during ANC, were tested, and received their test results ranges from 38 percent among those with no education to 75 percent among those with at least some secondary education. Likewise, women in the lowest wealth quintile (52 percent) were less likely than women in the highest quintile (79 percent) to have been counselled and tested and to have received their results. By county, 85 percent or more of women in Nairobi, Mombasa, Kisii, and Homa Bay were counselled about HIV during ANC, were tested, and received their test results, as compared with less than 20 percent of women in Mandera, Wajir, and Marsabit (Table 13.13C).

13.8 MALE CIRCUMCISION

The risk of acquisition of HIV by the circumcised male is reduced by 60 percent (Bailey, 2007). Circumcision is widely practiced in Kenya, mostly as a rite of passage to adulthood. Table 13.14 shows the percentage of men age 15-49 who report having been circumcised, by background characteristics. Ninety-three percent of Kenyan men are circumcised, an increase from both 2003 (84 percent) and 2008-09 (86 percent). Young men age 15-19 are least likely to be circumcised (87 percent), although this is still an increase from 76 percent in 2008-09.

Men from Nyanza are less likely to be circumcised (72 percent) than their counterparts in other regions. However, this is a noteworthy increase from the 45 percent of men in Nyanza who were circumcised according to the 2008-09 KDHS. Muslim men are most likely to be circumcised (99 percent). Circumcision is widespread among most ethnic groups except the Luo (59 percent) and Turkana (42 percent), although circumcision among Luo men has substantially risen (from 17 percent in 2003 and 22 percent in 2008-09). The counties with the lowest percentage of circumcised men include Turkana (26 percent), Siaya (56 percent), Homa Bay (56 percent), and Kisumu (59 percent) (Table 13.14C). Circumcision is virtually universal among men in Garissa, Wajir, Mandera, Kitui, Makueni, and Nyamira.

13.9 SELF-REPORTING OF SEXUALLY TRANSMITTED INFECTIONS

Information about the prevalence of sexually transmitted infections (STIs) is useful not only as a marker of unprotected sexual intercourse, but also because STI infection is a co-factor in HIV transmission. The 2014 KDHS asked respondents who had ever had sex whether they had suffered from a disease that they acquired through sexual contact in the past 12 months. They were also asked whether, in the past 12 months, they had any genital discharge and whether they had a genital sore or ulcer. These symptoms have been shown to be useful in identifying STIs in men. For women, however, discharge is

less easily interpreted as a symptom because women experience non-STI conditions of the reproductive tract that also produce discharge. Table 13.15 shows the self-reported prevalence of STIs and STI symptoms among women and men age 15-49, by background characteristics.

Two percent of both women and men reported having had an STI in the 12 months preceding the survey. Six percent of women and 2 percent of men reported recently experiencing an STI or STI symptoms. Women who are currently married or living together with a partner (6 percent) and those who are divorced, separated, or widowed (7 percent) have a higher prevalence of STIs and STI symptoms than women who have never been married (4 percent). Women in Coast (10 percent) and Western (11 percent) are more likely to have an STI or STI symptoms than women in other regions.

The prevalence of STIs or STI symptoms is higher among divorced, separated, or widowed men (6 percent) and uncircumcised men (6 percent) than among their counterparts. The highest prevalence of STIs and STI symptoms occurs in Nyanza (6 percent).

Table 13.15 Self-reported prevalence of sexually-transmitted infections (STIs) and STIs symptoms

Among women and men age 15-49 who ever had sexual intercourse, the percentage reporting having an STI and/or symptoms of an STI in the past 12 months, by background characteristics, Kenya 2014

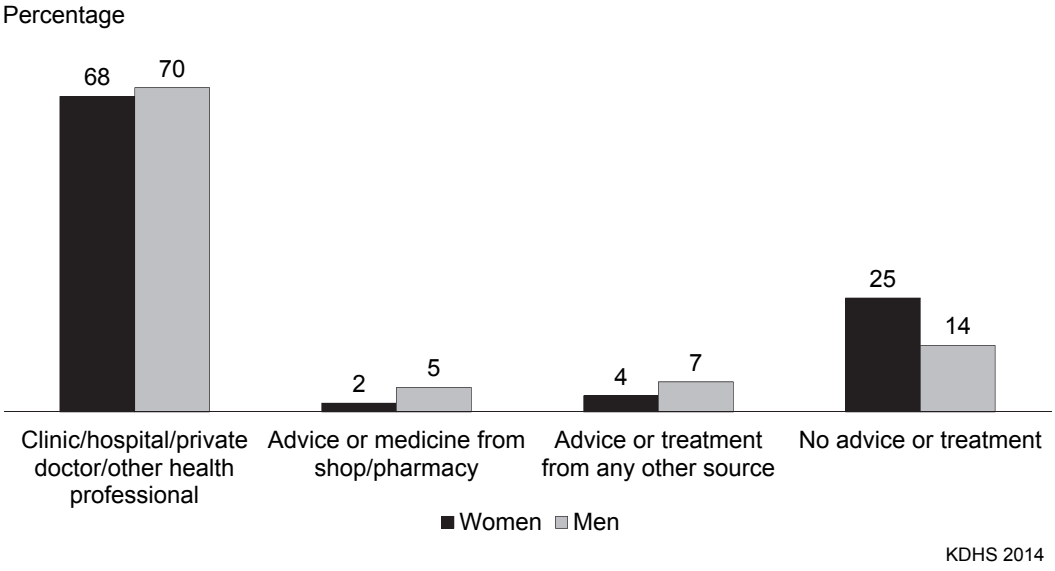
Figure 13.5 shows that most women and men who reported having an STI or STI symptoms sought advice or treatment from a clinic, hospital, private doctor, or other health facility (68 percent and 70 percent, respectively). Twenty-five percent of women and 14 percent of men did not seek any treatment.

Figure 13.5 **Women and men seeking treatment for STIs**



13.10 PREVALENCE OF MEDICAL INJECTIONS

Table 13.16 shows the percentage of women and men age 15-49 who received at least one medical injection in the 12 months that preceded the survey, the average number of medical injections in the last 12 months, and, among those who received a medical injection, the percentage whose last injection was administered with a syringe and needle taken from a new, unopened package.

Forty-seven percent of women and 32 percent of men reported having received a medical injection in the last 12 months. Ninety-nine percent of women and 98 percent of men reported that the syringe and needle used to administer their last injection were taken from a new, unopened package. Women in North Eastern (83 percent) and women with no education (94 percent) were less likely than their counterparts to report that their most recent injection was administered with a syringe from a new, unopened package; similar results are seen for men with no education (94 percent).

Table 13.16 Prevalence of medical injections

Percentage of women and men age 15-49 who received at least one medical injection in the last 12 months, the average number of medical injections per person in the last 12 months, and among those who received a medical injection, the percentage of last medical injections for which the syringe and needle were taken from a new, unopened package, by background characteristics, Kenya 2014

13.11 HIV/AIDS KNOWLEDGE AND SEXUAL BEHAVIOUR AMONG YOUTH

This section addresses HIV- and AIDS-related knowledge and sexual behaviour among youth age 15-24. In addition to knowledge of HIV transmission, data are presented on age at first sex, condom use, age differences between sexual partners, sex related to alcohol use, and voluntary counselling and testing for HIV.

Younger people are often at a higher risk of contracting STIs, as they are more likely to experiment with sex before marriage. Therefore, condom use among young adults plays an important role in the prevention of transmission of HIV and other sexually transmitted infections, as well as unwanted pregnancies. Likewise, knowledge of where to get condoms is an important prerequisite to their use.

13.11.1 HIV/AIDS-Related Knowledge among Youth

Table 13.17 shows comprehensive knowledge about AIDS and knowledge of a source of condoms among women and men age 15-24 by background characteristics. Fifty-seven percent of young women and 64 percent of young men have comprehensive knowledge about AIDS. Knowledge increases with age among both women and men and is lowest among women (50 percent) and men (55 percent) who have never had sex, women (15 percent) and men (25 percent) in North Eastern, rural women (52 percent) and men (61 percent), and women (14 percent) and men (23 percent) with no education. Seventy-one percent of young women and 88 percent of young men know a place where they can get condoms; trends by background characteristics are similar to those observed for comprehensive knowledge among young people.

Table 13.17 Comprehensive knowledge about AIDS and of a source of condoms among youth

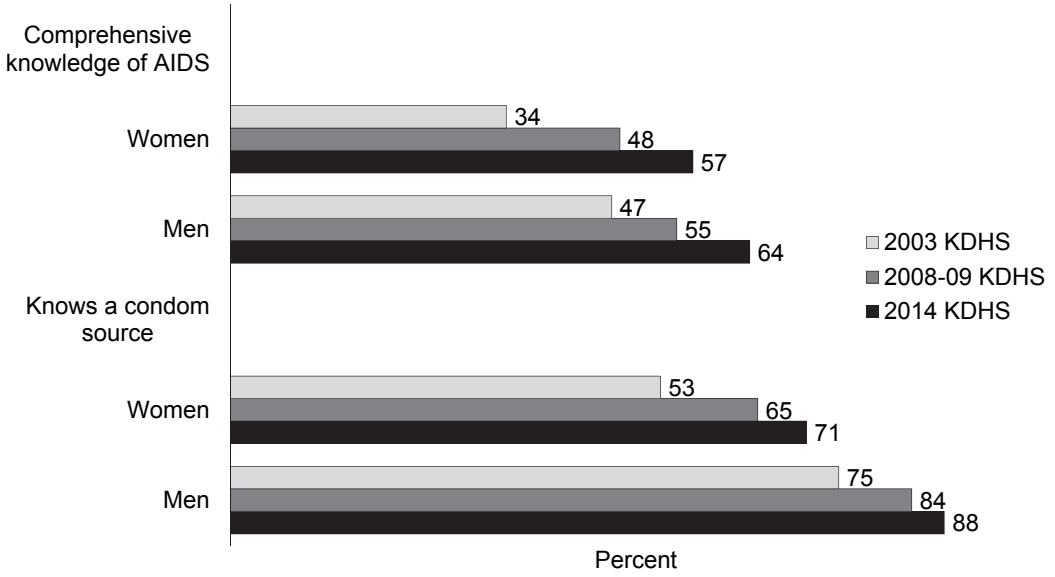
[1] Comprehensive knowledge means knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting the AIDS virus, knowing that a healthy-looking person can have the AIDS virus, and rejecting the two most common local misconceptions about AIDS transmission or prevention of the AIDS virus. The components of comprehensive knowledge are presented in Tables 13.2, 13.4.1 and 13.4.2.
[2] For this table, the following responses are not considered a source for condoms: friends, family members, and home.

Figure 13.6 shows trends in comprehensive knowledge about AIDS and knowledge of a source for condoms among women and men age 15-24. Comprehensive knowledge and knowledge of a condom source have steadily increased among young people since 2003.

Figure 13.6 **Comprehensive knowledge about AIDS and source of condoms among youth**



13.11.2 Trends in Age at First Sex

Because HIV transmission in Kenya occurs predominantly through heterosexual intercourse, age at first sexual intercourse marks the time at which individuals first risk exposure to the virus. Table 13.18 shows the percentage of women and men age 15-24 who had their sexual debut before age 15 and before age 18. Young men (21 percent) are almost twice as likely to engage in sexual intercourse before age 15 as young women (12 percent). By age 18, nearly half (47 percent) of women and more than half (55 percent) of men have had sexual intercourse.

Urban young women are less likely to initiate sexual activity before age 18 (39 percent) than rural young women (53 percent); there are no apparent rural-urban differences among young men. Among young women, the percentage who have had sexual intercourse before age 15 or before age 18 declines with increasing education. Young men who know a source of condoms are much more likely to have had sex by age 15 (23 percent) or age 18 (57 percent), although this pattern does not exist for young women. Women in Nyanza (21 percent) and men in Nyanza and Eastern (27 percent each) are more likely than their counterparts to have had sex before age 15.

Table 13.18 Age at first sexual intercourse among young people

Percentage of young women and young men age 15-24 who had sexual intercourse before age 15 and percentage of young women and young men age 18-24 who had sexual intercourse before age 18, by background characteristics, Kenya 2014

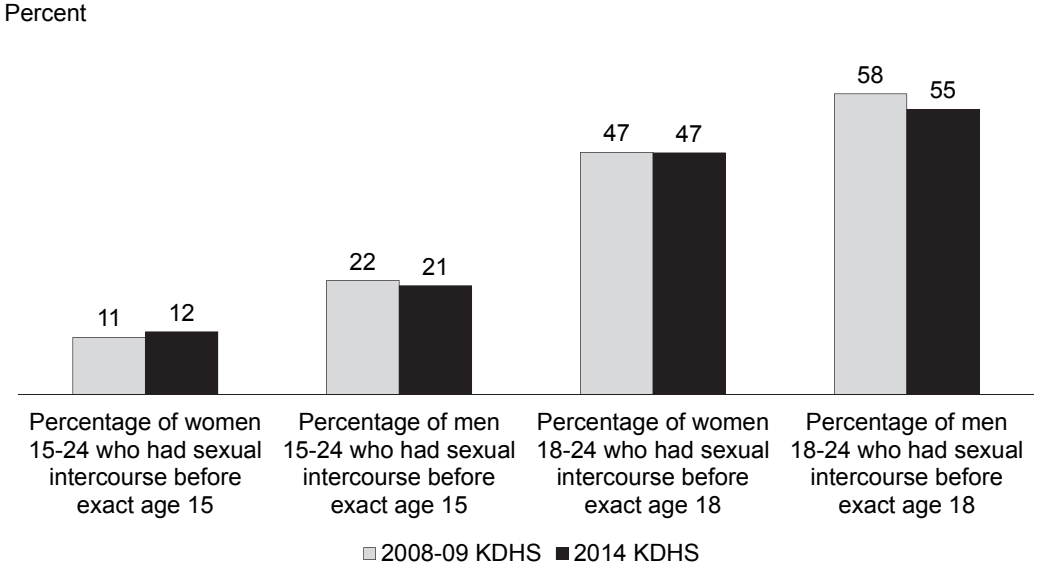
[1] For this table, the following responses are not considered a source for condoms: friends, family members and home.

Figure 13.7 compares trends in age at first sex between the 2008-09 KDHS and 2014 KDHS surveys; there have been no substantial changes over time.

Figure 13.7 **Trends in age of first sexual intercourse**



13.11.3 Abstinence and Premarital Sex

Premarital sex and the interval between sexual initiation and marriage are among the factors that may increase exposure to HIV infection. Table 13.19 shows the percentage of never-married young women and men age 15-24 who have never had sex, the percentage who had sex in the 12 months preceding the survey, and, among those who had sex in the 12 months preceding the survey, the percentage who used a condom during their most recent sexual encounter.

Table 13.19 Premarital sexual intercourse and condom use during premarital sexual intercourse among youth

Among never-married women and men age 15-24, the percentage who have never had sexual intercourse, the percentage who had sexual intercourse in the past 12 months, and, among those who had premarital sexual intercourse in the past 12 months, the percentage who used a condom at the last sexual intercourse, by background characteristics, Kenya 2014

	Women					Men

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] For this table, the following responses are not considered a source for condoms: friends, family members and home.

Twenty-six percent of young women and 42 percent of young men had sex in the 12 months before the survey. Sixty-one percent of women and 75 percent of men used a condom during their last sexual encounter. Among both women and men, the proportion who had sex in the past 12 months and used a condom during their most recent sexual encounter increases with age and knowledge of a condom source. Young women (1 percent) and men (3 percent) from North Eastern are least likely to report having had sex in the 12 months before the survey. Women and men in urban areas and those at higher educational levels are more likely than their counterparts to have had sex in the past 12 months and to have used a condom during their most recent sexual encounter.

In the last decade, the percentage of women and men age 15-24 who used a condom during their last premarital sexual intercourse has steadily increased. Among women, condom use increased from 27 percent in 2003 and 40 percent in 2008-09 to 61 percent in 2014. Similarly, condom use among men increased from 48 percent in 2003 and 64 percent in 2008-09 to 75 percent in 2014.

13.11.4 Multiple Sexual Partners among Youth

Having multiple sexual partners and having unprotected sex increase one's chances of both contracting and transmitting HIV. The percentage of women and men age 15-24 who had more than one sexual partner in the past 12 months and the percentage who reported using a condom during their last intercourse are presented in Table 13.20.1 and Table 13.20.2.

More men than women reported having two or more sexual partners (10 percent and 2 percent, respectively). Ever-married young women and men (3 percent and 15 percent, respectively) were more likely than their never-married counterparts (1 percent and 9 percent, respectively) to have had two or more partners in the past 12 months. The proportion of women (2 percent) and men (13 percent) with multiple partners is higher in urban areas.

Among respondents reporting two or more sexual partners in the past 12 months, 38 percent of women and 69 percent of men used a condom during their most recent sexual encounter. The proportion of men who used a condom during their last sexual encounter was lowest among those who had ever been married (37 percent) and highest among those residing in urban areas (71 percent).

Table 13.20.1 Multiple sexual partners in the past 12 months among young people: Women

Among all young women age 15-24, the percentage who had sexual intercourse with more than one sexual partner in the past 12 months, and among those having more than one partner in the past 12 months, the percentage reporting that a condom was used at last intercourse, by background characteristics, Kenya 2014

[1] For this table, the following responses are not considered a source for condoms: friends, family members and home.

13.11.5 Cross-generational Sexual Partners

To examine age differences between sexual partners, women and men age 15-19 who had sex in the 12 months preceding the survey were asked the age of their partners. If they did not know a partner's age, they were asked whether the partner was older or younger than they were and, if older, whether the partner was 10 or more years older.

As shown in Table 13.21, women are more likely (14 percent) than men (1 percent) to have had sex with a partner 10 or more years older. Among women, this is an increase from 2008-09 (4 percent). Urban women (18 percent) and women with no education (42 percent) are most likely to have had sex with a partner 10 or more years their senior.

Table 13.21 Age-mixing in sexual relationships among women and men age 15-19

Among women and men age 15-19 who had sexual intercourse in the past 12 months, percentage who had sexual intercourse with a partner who was 10 or more years older than themselves, by background characteristics, Kenya 2014

[1] For this table, the following responses are not considered a source for condoms: friends, family members and home.

13.11.6 Voluntary HIV Counselling and Testing among Youth

People's knowledge of their HIV status can motivate them to practice safer sexual behaviour to avoid transmitting the virus to others. Table 13.22 shows, among women and men age 15-24 who reported having sexual intercourse in the past 12 months, the percentage who were tested for HIV and received their results in the past 12 months.

Young women are more likely (69 percent) than young men (54 percent) to have been tested for HIV and to have received the results in the 12 months preceding the survey. These figures represent a substantial increase from the 2008-09 KDHS, when 41 percent of women and 26 percent of men age 15-24 had been tested for HIV and received the results in the 12 months preceding the survey.

The likelihood of having been tested increases with age among both women and men. Ever-married men (61 percent) are more likely than never-married men to have been tested. Both women (71 percent) and men (56 percent) who know a condom source are more likely to have been tested. The prevalence of testing is highest among women and men in Nairobi (75 percent and 67 percent, respectively) and Nyanza (75 percent and 70 percent, respectively). Urban women (75 percent) and men (59 percent) are more likely to have been tested. Among both women and men, the likelihood of having been tested increases with increasing education.

Table 13.22 Recent HIV tests among youth

Among young women and young men age 15-24 who have had sexual intercourse in the past 12 months, the percentage who were tested for HIV in the past 12 months and received the results of the last test, by background characteristics, Kenya 2014

NONCOMMUNICABLE DISEASES AND OTHER HEALTH ISSUES

14

James Muttunga, John Anampiu, Abdulkadir Amin Awes

Key Findings

- Overall, 10 percent of women have had both a breast exam from a health provider and a breast self-exam.
- Three-quarters (76 percent) of women have heard of cervical cancer, and 14 percent have had a cervical cancer screening exam.
- Approximately two-thirds (65 percent) of men have heard of prostate cancer, and 3 percent have been examined by a doctor or health care provider for prostate cancer.
- Tobacco use is more common among Kenyan men than women (83 percent of men don't use tobacco compared with 99 percent of women). Sixteen percent of men smoke cigarettes. Among men who smoke cigarettes, 28 percent smoked more than 10 cigarettes in the past 24 hours.
- Most Kenyans do not have health insurance; 82 percent of women and 79 percent of men are not covered by any health insurance.

14.1 INTRODUCTION

A healthy population is an end in itself, along with being one of the most basic requirements for quality of life and a basic foundation for a country's economic growth and development. It is important for the population to live a healthy lifestyle, free from communicable and noncommunicable diseases and free from use of destructive substances. Around the world, the rapid increases in noncommunicable diseases such as cardiovascular diseases, diabetes, and cancer are becoming a challenge in achieving global progress. Kenya, similar to other countries that are in an epidemiological transition, is experiencing an increase in noncommunicable diseases, obesity, and other conditions associated with urbanisation and modern, less active lifestyles, combined with new and re-emerging infectious diseases such as HIV and AIDS and tuberculosis. This chapter presents information on health issues in Kenya, including screening for noncommunicable diseases (NCDs), knowledge of tuberculosis, use of tobacco and alcohol, physical activity, accidental injury, and health insurance coverage.

14.2 KNOWLEDGE OF AND SCREENING FOR CANCER

In Kenya, cancer is estimated to be the second leading cause of NCD-related deaths after cardiovascular diseases, and it accounts for 7 percent of overall national mortality (WHO, 2014a). Cancer mortality can be reduced if cases are detected and treated early. Individuals and their physicians can participate in regular screening to identify abnormalities suggestive of cancer so that prompt diagnosis, treatment, and care can be sought. In the absence of early detection or screening, patients may be diagnosed at late stages when curative treatment is no longer an option (WHO, 2015b). The 2014 KDHS asked respondents if they had heard of specific types of cancers and if they had been screened for them. Women were asked about breast and cervical cancer, while men were asked about prostate cancer.

14.2.1 Breast Cancer

Breast cancer is one of the most common forms of cancer among women and is a leading cause of death worldwide. Breast self-examinations—physical examinations of the breasts performed by women

themselves—as well as examinations by medical professionals and mammography are methods for the early detection of breast cancer. Table 14.1 presents the percentage of women age 15-49 who have completed a breast self-exam for possible cancer and the percentage who have had a doctor or health care provider examine their breasts for cancer, by background characteristics.

Table 14.1 Breast cancer screening

Highest	41.2	22.7	18.3	3,827
Total	25.4	13.5	10.1	14,625

One-quarter (25 percent) of women have performed a breast self-examination, and 14 percent have had a doctor or health provider perform a breast exam. Overall, 10 percent of women have had both a self-exam and a breast exam from a health provider. The percentage of women who have had both exams increases with age and is most common among women age 25 and above. Urban women (15 percent) are more likely to have had both exams than rural women (7 percent). By region, the proportion of women who have had both exams ranges from 1 percent in North Eastern to 17 percent in Nairobi and Central. The likelihood of having both exams increases with increasing education and wealth. Fourteen percent of women with a secondary education have had both kinds of breast exam, as compared with 2 percent of women with no education. Similarly, 18 percent of women in the highest wealth quintile have had both kinds of breast exam, compared with 3 percent of women in the lowest wealth quintile.

14.2.2 Cervical Cancer

Worldwide, cervical cancer is the fourth most frequent cancer in women. When women are regularly screened for cervical cancer, pre-cancerous lesions and cancer are often identified at stages when they can easily be treated. Early treatment prevents up to 80 percent of cervical cancers. Because pre-cancerous lesions and cancer may take many years to develop, screening is recommended for every woman

age 30 to 49 at least once in her lifetime and ideally more frequently (WHO, 2015c). Two common types of screening examinations are the pap smear test and visual inspection with acetic acid (VIA) or with Lugol's iodine (VILI).

Table 14.2 presents the percentage of women age 15-49 who have heard of cervical cancer and the percentage who have had a cervical cancer screening exam. Among women who have had an exam, Table 14.2 presents the percent distribution by examination type.

About three-quarters (76 percent) of women have heard of cervical cancer and 14 percent have had a cervical cancer screening exam. Among women who have had an exam, 62 percent have had a pap smear, 32 percent have had visual inspection, and 1 percent have had both screening tests. Knowledge of cervical cancer and likelihood of having a screening exam are lowest among young women age 15-19 (59 percent and 2 percent, respectively), rural women (71 percent and 11 percent), women in North Eastern (5 percent and less than 1 percent), women with no education (33 percent and 3 percent), and women in the lowest wealth quintile (49 percent and 4 percent).

Table 14.2 Cervical cancer knowledge and screening

Percentage of women age 15-49 who have heard of cervical cancer and the percentage who have had a cervical cancer screening exam; and among women who have had a cervical cancer screening exam, the percent distribution by examination type, according to background characteristics, Kenya 2014

14.2.3 Prostate Cancer

Prostate cancer starts in the prostate gland, which is a small, walnut-sized structure that makes up part of a man's reproductive system. Prostate cancer can be detected through a digital rectal exam. Also, the blood level of prostate-specific antigen, a protein that is produced by the prostate, can be tested. Table

14.3 presents the percentage of men age 15-49 who have heard of prostate cancer and the percentage who have been examined for prostate cancer by a doctor or health care provider. Among men who have had an exam, Table 14.3 presents the timing of the exam and the exam results.

About two-thirds (65 percent) of men have heard of prostate cancer and 3 percent have been examined by a doctor or health care provider for prostate cancer. Among men who have had an exam, 82 percent have had the exam in the last five years, and 2 percent were told they had a problem with their prostate. Men age 15-19 (41 percent), men in rural areas (62 percent), and men in North Eastern (23 percent) were least likely to have heard of prostate cancer. Men with these characteristics were also less likely to have had a prostate exam. Knowledge of prostate cancer and the likelihood of having had a prostate exam generally increase with increasing education and wealth.

Table 14.3 Prostate cancer knowledge and screening

Percentage of men age 15-49 who have heard of prostate cancer, the percentage who have had a doctor or health care provider examine them for prostate cancer; and among men who have had a prostate cancer exam, the timing of the exam and the results, by background characteristics, Kenya 2014

14.3 SCREENING FOR HYPERTENSION AND DIABETES

Elevated blood pressure, commonly referred to as hypertension, is among the major risk factors for cardiovascular disease and stroke. Diabetes is characterised by chronic hyperglycaemia or raised blood sugar. It requires lifelong treatment and can damage the heart, blood vessels, eyes, kidneys, and nerves. The KDHS asked respondents if they had ever been told by a doctor or health worker that they had high

blood pressure or hypertension or that they had raised blood sugar or diabetes. Table 14.4 presents the percentage of women and men age 15-49 who were told they had either of these health concerns, according to background characteristics. It is important to note that these data do not represent the prevalence of hypertension or diabetes in Kenya; rather, they reflect only the proportion of people who have visited a health care provider, undergone an examination, and been informed that they have these health concerns.

Nine percent of women and 3 percent of men have been told by a health care provider that they have hypertension. The percentage of women and men who have been told they have hypertension generally increases with age, education, and wealth. Women and men in urban areas, women in Nairobi and Central regions, and men in Nairobi and Nyanza regions are more likely to have been told they have hypertension, although this pattern may reflect increased access to health care in these areas. One percent of both women and men have been told by a health care provider that they have diabetes.

Table 14.4 Hypertension and diabetes screening

Percentage of women and men age 15-49 who were told by a doctor or health worker that they have raised blood pressure or hypertension and the percentage who were told by a doctor or health worker that they have raised blood sugar or diabetes, according to background characteristics, Kenya 2014

14.4 KNOWLEDGE AND ATTITUDES CONCERNING TUBERCULOSIS

The 2014 KDHS collected data on women's and men's knowledge and attitudes concerning tuberculosis (TB). Tables 14.5.1 and 14.5.2 show the percentage of women and men who have heard of TB and, among those who have heard of TB, the percentage who know that TB is spread through the air by coughing.

As in the 2008-09 KDHS, awareness of TB is almost universal in Kenya (97 percent among women and 99 percent among men). Eighty-four percent of women and 87 percent of men age 15-49 who have heard of TB know that it is spread through the air by coughing. Women and men in rural areas and those in Western region are less likely than their counterparts to know that TB is spread through the air by coughing. Correct knowledge of TB transmission increases with increasing education and wealth.

Table 14.5.1 Knowledge and attitudes concerning tuberculosis: Women

Percentage of women age 15-49 who have heard of tuberculosis (TB), and among women who have heard of TB, the percentages who know that TB is spread through the air by coughing, by background characteristics, Kenya 2014

14.5 USE OF TOBACCO

Smoking and using other forms of tobacco can cause a wide variety of diseases and lead to death. Smoking is a risk factor for NCDs, including cardiovascular disease, lung cancer, and other forms of cancer, and it contributes to the severity of pneumonia, emphysema, and chronic bronchitis. Further, secondhand smoke may adversely affect health and aggravate illnesses. In the 2014 KDHS, women and men age 15-49 were asked whether they currently smoke cigarettes and, if so, how many cigarettes they had smoked in the past 24 hours. Those who were not currently smoking cigarettes were asked whether they used any other forms of tobacco, such as a pipe, chewing tobacco, or snuff.

Tables 14.6.1 and 14.6.2 show that tobacco use is more common among Kenyan men than women (99 percent of women do not use tobacco compared with 83 percent of men). Sixteen percent of men age 15-49 smoke cigarettes, while a very small proportion of men chew tobacco, use snuff, or use other tobacco products (each 1 percent). Use of tobacco increases with age and is more common among men with no education and those in the lower wealth quintiles. In particular, cigarette smoking is most common among men in Eastern and Central regions (30 percent and 25 percent, respectively), men with less than a secondary education (20-21 percent), and men in the second wealth quintile (20 percent). Among men who smoke cigarettes, 18 percent smoked 1-2 cigarettes, 36 percent smoked 3-5 cigarettes, and 14 percent smoked 6-9 cigarettes in the past 24 hours. Twenty-eight percent of men who smoke cigarettes smoked more than 10 cigarettes in the past 24 hours.

Table 14.6.1 Use of tobacco: Women

Percentage of women age 15-49 who smoke cigarettes or a pipe or use other tobacco products, according to background characteristics and maternity status, Kenya 2014

14.6 ALCOHOL CONSUMPTION

Tables 14.7.1 and 14.7.2 show the percentage of women and men age 15-49 who drink alcohol and, among those who drink alcohol, the number of days at least one alcoholic drink was consumed in the past two weeks and the mean number of days on which alcohol was consumed in the past two weeks, by background characteristics. Men are more likely to consume alcohol than women (29 percent and 5 percent, respectively). Women over age 20 (5-7 percent) and men over age 25 (36-45 percent) are more likely than younger women and men to consume alcohol. Women and men in urban areas and in Nairobi are more likely to consume alcohol than their counterparts living elsewhere. Alcohol consumption among women is not clearly associated with education or wealth; among men, however, the proportion who drink alcohol generally increases with increasing education and wealth.

Among respondents who drink alcohol, 48 percent of women and 19 percent of men reported that they had not consumed alcohol in the past two weeks. Twenty-nine percent of women and 39 percent of men reported that they had consumed alcohol on 1-2 days during the last two weeks; 10 percent and 17 percent, respectively, had consumed alcohol on 3-4 days during the last two weeks, and 13 percent and 26 percent, respectively, had consumed alcohol on 5 or more days. Among women who drink alcohol, daily alcohol consumption in the past two weeks was higher among those age 45-49, those in rural areas, those in Coast and Eastern regions, those at lower educational levels, and those in lower wealth quintiles. Among men, daily alcohol consumption in the past two weeks was higher among those above age 30, those in Nyanza and Coast regions, and those with no education. Men in the highest wealth quintile were least likely to report daily consumption.

Table 14.7.1 Alcohol consumption: Women

Percentage of women age 15-49 who drink alcohol, and among those who drink alcohol, the number of days at least one alcoholic drink was consumed in the past two weeks, and the mean number of days alcohol was consumed in the past two weeks, by background characteristics, Kenya 2014

Background characteristic	Percentage who drink alcohol	Number of women	Among women who drink alcohol, the number of days at least one drink was consumed in the last two weeks								Number of women	Mean number of days

14.7 PHYSICAL ACTIVITY

The World Health Organization (WHO) defines physical activity as any bodily movement produced by skeletal muscles that requires energy expenditure, including activities undertaken while working, playing, carrying out household chores, travelling, and engaging in recreational pursuits. In order to be beneficial for cardiorespiratory health, physical activity should be performed in bouts of at least 10 minutes in duration. WHO recommends regular and adequate levels of physical activity to reduce the risk of NCDs, including hypertension, coronary heart disease, stroke, diabetes, and breast and colon cancer (WHO, 2010b).

In the 2014 KDHS, women and men age 15-49 were asked if they engaged in exercise that causes an increase in their heart rate for at least 10 minutes continuously at work or during other activities. Results are shown in Tables 14.8.1 and 14.8.2 for women and men, respectively. Sixty-two percent of women and 59 percent of men are not involved in exercise that causes an increase in their heart rate for at least 10 minutes continuously. Among women, 15 percent are involved in exercise at work, 12 percent are involved in exercise outside of work, and 12 percent are involved in exercise both at work and elsewhere. Among men, 18 percent are involved in exercise at work, 24 percent in exercise outside of work, and 17 percent in exercise both at work and elsewhere.

Overall, women above age 35, women in rural areas, and women in Western region were more likely to engage in 10 minutes of continuous physical activity than their counterparts. Women with no education and women in the highest wealth quintile were less likely to be physically active for 10 minutes continuously. In contrast, men age 29 and younger and those in Coast and North Eastern regions were more likely to engage in 10 minutes of continuous physical activity than their counterparts. Men with a secondary or higher education were more likely to be physically active, as were men in the highest wealth quintile.

Table 14.8.1 Physical activity: Women

Percent distribution of women age 15-49 who are involved in exercise that causes an increase in their heart rate for at least 10 minutes continuously, by background characteristics, Kenya 2014

14.8 UNINTENTIONAL INJURY

Tables 14.9.1 and 14.9.2 present the percentage of women and men age 15-49 unintentionally injured in the past 12 months and the percentage involved in a road traffic accident in the past 12 months. Among those injured unintentionally (excluding involvement in traffic accidents), the cause of injury is presented, according to background characteristics. One in five women (20 percent) and one in three men (33 percent) experienced an unintentional injury in the past 12 months. Three percent of women and 9 percent of men were involved in a road traffic accident in the last 12 months. Excluding road traffic accidents, the most common causes of injury among women were cuts (60 percent), falls (40 percent), and burns (20 percent). Among men, the most common causes were cuts (66 percent) and falls (33 percent).

Although there are no apparent rural-urban differences, there are differences by region; overall, women in Nyanza (29 percent) were more likely to have been injured in the past 12 months than women in other regions. Also, women in Nyanza were more likely than those in other regions to have been involved in a road traffic accident (5 percent) and to report having been cut (70 percent).

Younger men age 15-19 and 20-24 (both 35 percent) were slightly more likely to have experienced an unintentional injury in the past 12 months than older men (31-34 percent). Also, men in rural areas (37 percent) were more likely to have experienced an injury than urban men. A higher proportion of men in Nyanza (46 percent) and Central regions (43 percent) reported having been injured. Men in Nyanza were more likely to report involvement in a road traffic accident (18 percent). Unintentional injury does not appear to be related to education or wealth among either women or men.

Table 14.9.1 Unintentional injury: Women

Percentage of women age 15-49 unintentionally injured in the past 12 months and percentage involved in a road traffic accident in the past 12 months; and among women injured unintentionally, the percentage by cause of injury, according to background characteristics, Kenya 2014

Background characteristic	Percentage unintentionally injured in the past 12 months	Percentage involved in a road traffic accident in the past 12 months[1]	Number of women	Cause of injury:								Number of women injured unintentionally[2]

14.9 HEALTH INSURANCE COVERAGE

Health insurance can be crucial in disease management and access to quality health care since insurance can reduce the costs associated with illness, treatment, and care substantially. The 2014 KDHS asked respondents if they were covered by any health insurance and, if so, what type. Table 14.10.1 and Table 14.10.2 show the percentage of women and men age 15-49 with specific types of health insurance. Most Kenyans age 15-49 do not have health insurance (82 percent of women and 79 percent of men).

Among those who do have coverage, the national insurance scheme is the most common type for both women (14 percent) and men (18 percent). Employer-based insurance is the next most common, accounting for 2 percent of insured women and 3 percent of insured men. One percent or less of women and men have some other type of insurance. Health insurance coverage is more common among women and men age 25 or above, those living in urban areas, and those residing in Nairobi and Central regions. Insurance coverage increases with increasing education and wealth.

WOMEN'S EMPOWERMENT AND DEMOGRAPHIC AND HEALTH OUTCOMES 15

Robert C.B. Buluma, Rosemary Uside Kongani, Godfrey Odhiambo Otieno

Key Findings

- Nearly half (49 percent) of currently married employed women who earn cash make independent decisions about how to spend their earnings, an increase from the figure of 42 percent reported in the 2008-09 KDHS.
- Fifty-four percent of currently married women participate in four common household decisions, including decisions pertaining to their own health care, major household purchases, visits to their family or relatives, and major household purchases. Thirty-nine percent of women have the main say in their own health care.
- Contraceptive use increases with women's empowerment.
- In general, unmet need for family planning decreases with improvements in women's empowerment.
- Access to antenatal care, delivery assistance from a skilled provider, and postnatal care within the first two days of delivery increases with increasing women's empowerment.

Women's empowerment encompasses women's sense of self-worth, access to opportunities, access to and control of resources, choices and the ability to exercise them, control over their own lives, and influence over the direction of social change (United Nations Population Information Network, 1995).

Women's empowerment is supported internationally and in Kenya. The 1994 International Conference on Population and Development declared that "advancing gender equality and equity and the empowerment of women and the elimination of all kinds of violence against women, and ensuring women's ability to control their own fertility are cornerstones of population and development-related programs" (United Nations, 1994). Furthermore, Kenya is a signatory to many international conventions on human rights, women's rights, reproductive health rights, and children's rights, as well as to agreements on international goals regarding education, health, and poverty eradication. As a signatory to the United Nations Convention on the Elimination of All Forms of Discrimination Against Women (CEDAW) and as mandated by the Constitution of Kenya promulgated in 2010, the government of Kenya is committed to ensuring nondiscrimination, gender equity, and social justice.

This chapter presents data on the status of women in Kenya, including information on employment, access to and control over cash earnings, asset ownership, participation in household decision making, relative earnings of husbands and wives, and attitudes towards wife beating. The chapter also explores how demographic and health indicators are affected by women's empowerment, as measured by the number of decisions in which women participate and the number of situations in which they believe wife beating is justified. The ranking of women on these indices has been found to be associated with demographic and health outcomes, including contraceptive use, unmet need for family planning, access to reproductive health care, and child survival.

15.1 EMPLOYMENT AND FORM OF EARNINGS

Employment, especially for cash, and control over how earnings are used are important indicators of empowerment for both women and men. Table 15.1 shows the percentage of currently married women and men age 15-49 who were employed at any time in the 12 months before the survey and the percent distribution of employed women and men by the type of earnings they received (cash only, cash and in-kind, in-kind only). Only 75 percent of currently married women age 15-49 were employed in the past 12 months, as compared with virtually all currently married men. The results show an improvement over time in the proportion of employed women, from 67 percent in the 2008-09 KDHS to 75 percent in 2014. There is no difference from 2008-09 to 2014 in the proportion of men who were employed. The majority of those employed were earning cash only (women, 61 percent; men, 82 percent); 15 percent of women and 10 percent of men had cash and in-kind earnings, and 4 percent of women and 1 percent of men had in-kind earnings only. A higher proportion of women (20 percent) than men (7 percent) were not paid for their work.

Table 15.1 Employment and cash earnings of currently married women and men

Percentage of currently married women and men age 15-49 who were employed at any time in the past 12 months and the percent distribution of currently married women and men employed in the past 12 months by type of earnings, according to age, Kenya 2014

Note: An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.

Employment increases with age. Younger women age 15-19 are less likely to be employed (48 percent) than older women age 45-49 (86 percent). The proportion who earn cash only is higher among women age 25-29 (65 percent) and among men age 20-24 (85 percent), while women and men age 45-49 are least likely to earn cash only (51 percent and 76 percent of men).

15.2 CONTROL OVER AND RELATIVE MAGNITUDE OF WOMEN'S AND HUSBANDS' EARNINGS

Access to and control of resources, including women's control over their earnings, is one dimension of women's empowerment. Currently married women who earn cash for their work were asked who mainly decides how the cash is used and the relative magnitude of their earnings compared with their husband's earnings. This information may provide some insight into women's empowerment within the family and the extent of their control over decision making in the household. It is expected that employment and earnings are more likely to empower women if women themselves control their own earnings and perceive their earnings as significant relative to those of their husbands or partners.

15.2.1 Control over Wife's Earnings

Table 15.2.1 shows the percent distribution of currently married women age 15-49 who received cash earnings in the 12 months preceding the survey according to the person who decides how their earnings are used and according to whether they earn more or less than their husband, by background characteristics. One-half (49 percent) of currently married women decide how their cash earnings are used, while 41 percent of women report that decisions about their earnings are made jointly with their husbands. Only a small proportion of women (9 percent) report that decisions about their earnings are made exclusively by their husbands. Seventy-two percent of currently married women age 15-49 earn less than their husbands, while 11 percent earn more and 13 percent earn about the same.

Table 15.2.1 Control over women's cash earnings and relative magnitude of women's cash earnings

Percent distribution of currently married women age 15-49 who received cash earnings for employment in the 12 months preceding the survey by person who decides how wife's cash earnings are used and by whether she earned more or less than her husband, according to background characteristics, Kenya 2014

	Person who decides how the wife's cash earnings are used:						Wife's cash earnings compared with husband's cash earnings:

The proportion of currently married women who make independent decisions on how their cash earnings are used increased from 42 percent in 2008-09 to 49 percent in 2014. The data further show that the proportion of wives who make decisions about their earnings jointly with their husbands declined from 49 percent to 41 percent over the same period.

There is no clear pattern in decision making on use of cash earnings according to the woman's age. Women age 15-19, women with more living children, urban women, and women in the lowest wealth quintile are more likely than other women to act as the main decision makers in the use of their earnings. Women in the Nairobi (59 percent) and Western (58 percent) regions are more likely to make decisions alone about their earnings than those in other regions. Women in Eastern are least likely to be the main

decision makers regarding the use of their income; however, that region reported the highest proportion of women who jointly make decisions with their husbands on the use of their earnings.

Regarding the relative magnitude of women's earnings with those of their husbands, older women, women with five or more children, and women who live in North Eastern region are more likely to earn more than their husband. The likelihood a woman earns more than her husband decreases with education and wealth.

15.2.2 Control over Husbands' Earnings

Table 15.2.2 shows the percent distributions of currently married men age 15-49 who receive cash earnings and currently married women age 15-49 whose husbands receive cash earnings, according to the person who decides how the husband's cash earnings are used. Fifty-five percent of currently married men age 15-49 who earn cash decide jointly with their wives how their earnings are used, as compared with 49 percent of women who indicated that joint decisions are made. About 4 in 10 men and women (41 percent and 42 percent, respectively) reported that the husband mainly decides how his cash earnings are used. A small proportion (4 percent of currently married men and 9 percent of currently married women) reported that the wife acts as the main decision maker in the use of the husband's earnings.

Table 15.2.2 Control over men's cash earnings

na = Not applicable

There are few distinct patterns in how decisions about the use of a husband's earnings are made. However, younger men age 20-24, men with no education, and men in the lowest wealth quintile are more likely than other men to have the main say in the use of their earnings. It follows that men with these characteristics are less likely to engage in joint decision making in use of their earnings. Among women, few patterns are discernible. The proportion of women who report that their husband mainly decides how his earnings are used increases with increasing number of living children and, in general, decreases with increasing education and with increasing wealth.

Regional variations are evident, with a much higher proportion of men in Eastern (69 percent) and Central (67 percent) than in North Eastern (4 percent) indicating that the husband and wife jointly decide how the husband's cash earnings are used. In addition, women in Eastern (63 percent) are much more likely than women in Nyanza (37 percent) and Western (36 percent) to report that they and their husbands jointly decide how the husband's cash earnings are used.

15.3 CONTROL OVER WOMEN'S EARNINGS AND RELATIVE SIZE OF HUSBAND'S AND WIFE'S EARNINGS

Table 15.3 shows who decides how the woman's cash earnings are used, according to the relative magnitude of the woman's and the husband's cash earnings. Women whose cash earnings are less than their husbands' and women whose husbands do not have cash earnings are more likely to decide for themselves how their earnings are used (53 percent and 60 percent, respectively). In contrast, women are more likely to report joint decision making on the use of their earnings when they earn the same as their husband (65 percent) or more than their husband (47 percent).

Table 15.3 Women's control over their own earnings and over those of their husbands

Percent distribution of currently married women age 15-49 with cash earnings in the last 12 months by person who decides how the wife's cash earnings are used and percent distribution of currently married women age 15-49 whose husbands have cash earnings by person who decides how the husband's cash earnings are used, according to the relation between wife's and husband's cash earnings, Kenya 2014

na = Not applicable
[1] Includes 122 cases where a woman does not know whether she earned more or less than her husband

Table 15.3 also shows who decides how the husband's cash earnings are used, according to the relative magnitude of the woman's and the husband's cash earnings. Women who earn less than their husband are more likely to report that their husband has the main say in deciding use of his earnings. Women who earn the same as their husband and women who earn more than their husband are more likely to report joint decision making in the use of their husband's earnings (67 percent and 50 percent, respectively). Since the 2008-09 KDHS, these indicators show marginal improvements or have remained stable.

15.4 OWNERSHIP OF ASSETS

Ownership and control of assets by women and men gives an enhanced picture of their access to economic resources. Ownership of assets confers additional economic value, status, and bargaining power.

For women in particular, ownership of assets may provide protection in case of marital dissolution or abandonment, positively influence their position in the home, and decrease their vulnerability to various forms of violence or discrimination. Respondents were asked if they own a house or land alone, jointly with someone else, or both alone and jointly. Table 15.4.1 shows the percent distribution of women age 15-49 by ownership of housing and land, according to background characteristics.

Table 15.4.1 Ownership of assets: Women

Note: Totals may not add up to 100 percent because women with missing information are not shown separately.

Forty-two percent of women own a house and 39 percent of women own land (alone, jointly, or both). Among women, joint ownership is the most common type of home or land ownership; 31 percent own a house jointly, and 28 percent own land jointly. Eight percent of women own a house alone, and 7 percent own land alone. The percentage of women who own a house or land increases with age. Ownership of either is also more likely among women in rural areas than among their counterparts in urban areas. Likelihood of ownership decreases with increasing education and with increasing wealth.

Table 15.4.2 provides details of asset ownership among men age 15-49. Forty-nine percent of men own a house and 44 percent own land (alone, jointly, or both). In contrast to women, sole ownership is more common for men; 36 percent own a house alone, and 28 percent own land alone. Eleven percent own a house jointly, and 12 percent own land jointly. Similar to women, ownership of a house or land increases with age, and men in rural areas are more likely than those in urban areas to own a house; however, the rural-urban relationship is not evident for land ownership.

Table 15.4.2 Ownership of assets: Men

Percent distribution of men age 15-49 by ownership of housing and land, according to background characteristics, Kenya 2014

15.5 WOMEN'S PARTICIPATION IN DECISION MAKING

Decision making can be a complex process, and the ability of women to make decisions that affect their personal circumstances is an essential aspect of their environment and an indicator of their autonomy and control in their daily life. The 2014 KDHS collected information on women's participation in household decision making. Currently married women were asked who usually makes decisions about four specific issues: their own health care, major household purchases, visits to their family or relatives, and what food to cook each day. Currently married men were also asked who makes decisions about two specific issues: their own health care and major household purchases.

Table 15.5 shows the percent distribution of currently married women and men age 15-49 according to the person who usually makes decisions concerning these matters. Women are considered to participate in decision making if they usually make decisions alone or jointly with their husbands. Women's involvement in decision making varies according to the type of decision. Eighty-three percent of women decide solely what food should be cooked each day, a domain commonly relegated to women. A much smaller percentage have the main say in other household decisions. Thirty-nine percent of women act as the main decision maker in their own health care, while 40 percent say this decision is made jointly with their husband and 21 percent say their husband mainly decides. Less than one-quarter of women are the main decision makers about visits to their family or relatives (23 percent) and major household purchases (20 percent). These decisions are mostly made jointly with the husband (50 percent and 53 percent, respectively) or mainly by the husband (26 percent and 27 percent, respectively).

Table 15.5 Participation in decision making

Percent distribution of currently married women and currently married men age 15-49 by person who usually makes decisions about various issues, Kenya 2014

Decision	Mainly wife	Wife and husband jointly	Mainly husband	Someone else	Other	Missing	Total	Number
			WOMEN					
Own health care	38.6	40.1	20.9	0.2	0.1	0.2	100.0	8,710
Major household purchases	19.6	52.9	27.0	0.2	0.1	0.2	100.0	8,710
Visits to her family or relatives	23.2	50.2	26.1	0.2	0.1	0.2	100.0	8,710
What food should be cooked each day	82.9	10.7	5.0	1.0	0.2	0.2	100.0	8,710
			MEN					
Own health care	5.9	42.2	51.3	0.2	0.2	0.3	100.0	6,095
Major household purchases	9.7	56.1	33.8	0.1	0.1	0.3	100.0	6,095

Men are more likely to be the main decision makers regarding their own health care (51 percent), while decisions about major household purchases are more likely to be made jointly (56 percent). Less than 10 percent of men reported that their wife was the main decision maker regarding either of these specific issues.

Table 15.6.1 shows the percentage of currently married women age 15-49 who usually make specific decisions either by themselves or jointly with their husbands, by background characteristics. In general, women's participation in decision making increases with age, education, and wealth quintile. Women who reside in urban areas and women who are employed and earning cash appear slightly more likely to be involved in decision making than their counterparts. Women in the Central and Eastern regions are generally more involved in decision making than women in other regions, while women in the Western region are least likely to have a say in household decisions.

Table 15.6.1 Women's participation in decision making by background characteristics

Percentage of currently married women age 15-49 who usually make specific decisions either by themselves or jointly with their husband, by background characteristics, Kenya 2014

[1] Total includes six women for whom information on employment in the past 12 months is missing.

Figure 15.1 shows the number of decisions in which currently married women participate. More than one-half of currently married women (54 percent) participate in all four decisions, about one-fourth (23 percent) participate in three decisions, more than 1 in 10 (12 percent) participate in two decisions, and less than 1 in 10 participate in one (9 percent) or no decisions (2 percent).

Figure 15.1 **Number of decisions in which currently married women participate**

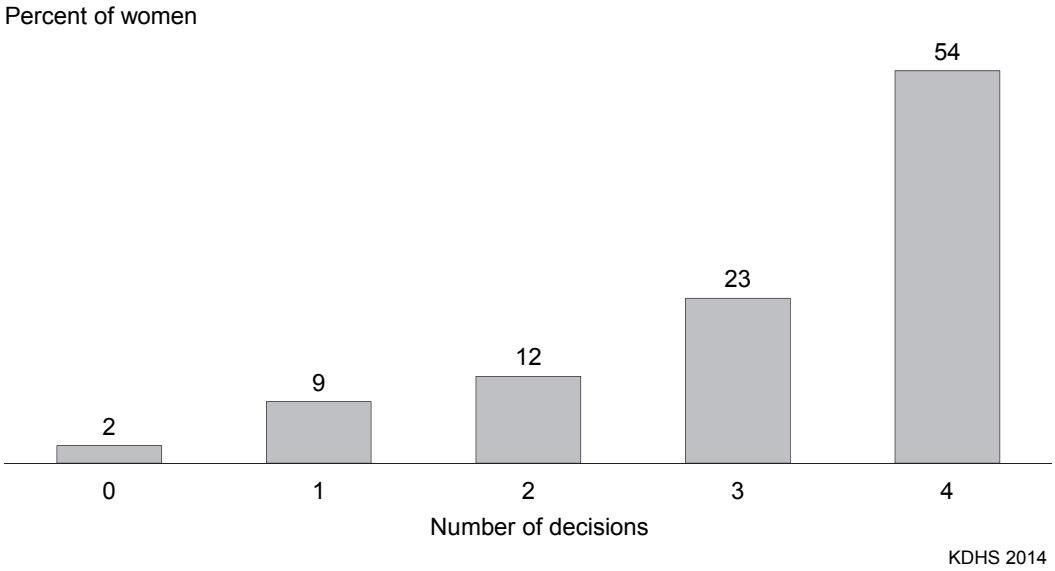

Table 15.6.2 presents the percentage of currently married men age 15-49 who usually make specific decisions either alone or jointly with their wife, by background characteristics. There are no obvious patterns evident in decision making for men by age, education, or wealth. However, unemployed men are less likely to be involved in decision making than those who are employed, and men in the Central and Eastern regions are generally more involved in decision making than men in other regions.

Table 15.6.2 Men's participation in decision making by background characteristics

[1] Total includes four men for whom information on employment in the past 12 months is missing.

15.6 ATTITUDES TOWARDS WIFE BEATING

One of the most common forms of violence against women worldwide is abuse by a husband or partner (Heise et al., 1999). The 2014 KDHS collected information on women's and men's attitudes towards wife beating. Respondents were asked whether a husband is justified in beating his wife under a series of circumstances: if the wife burns the food, argues with him, goes out without telling him, neglects the children, or refuses sexual relations. Women and men who believe that a husband is justified in hitting or beating his wife for any reason may believe women to be low in status, both absolutely and relative to men. Such a perception could act as a barrier to accessing health care for women, affect attitudes towards women's rights to contraception, and influence women's general well-being. Table 15.7.1 presents women's attitudes towards wife beating in regard to the five specific circumstances. The table also shows the percentage of women who agree that wife beating is justified for at least one of the specified reasons.

Table 15.7.1 Attitude towards wife beating: Women

Percentage of all women age 15-49 who agree that a husband is justified in hitting or beating his wife for specific reasons, by background characteristics, Kenya 2014

Background characteristic	Husband is justified in hitting or beating his wife if she:					Percentage who agree with at least one specified reason	Number of women
	Burns the food	Argues with him	Goes out without telling him	Neglects the children	Refuses to have sexual intercourse with him

Middle	8.0	25.1	24.7	39.0	18.3	49.4	2,859
Fourth	5.3	17.1	17.5	29.9	10.7	37.0	3,113
Highest	2.1	8.5	9.4	18.2	4.7	23.4	3,827
Total	7.0	21.0	21.8	33.3	15.1	41.8	14,625

Note: Total includes 13 women for whom information on employment in the past 12 months is missing.

Forty-two percent of women believe wife beating is justified for at least one of the specified reasons. Overall, acceptance of wife beating ranges from a high of 33 percent for neglecting the children to a low of 7 percent for burning the food. Women who are employed but not paid in cash and rural women are more likely to justify wife beating than their counterparts. The proportion of women who justify wife beating increases with increasing number of living children and decreases with increasing education and wealth. Acceptance of wife beating varies by region, from 19 percent of women in Nairobi to slightly more than one-half in North Eastern, Rift Valley, and Western (52-54 percent).

Table 15.7.2 presents the percentage of men age 15-49 who agree that a husband is justified in hitting or beating his wife for specific reasons, by background characteristics. Compared with women, men are less likely to agree that wife beating is justified. Thirty-six percent of men believe wife beating is

justified for at least one of the specified reasons. Overall, men's acceptance of wife beating ranges from a high of 27 percent for neglecting the children to a low of 5 percent for burning the food. Similar to women, men who are employed but not paid in cash are more likely to say wife beating is justified. Acceptance of wife beating decreases with increases in education and wealth. By region, the proportion of men who justify wife beating ranges from 25 percent in Western to 52 percent in North Eastern.

Table 15.7.2 Attitude towards wife beating: Men

Percentage of all men age 15-49 who agree that a husband is justified in hitting or beating his wife for specific reasons, by background characteristics, Kenya 2014

Background characteristic	Husband is justified in hitting or beating his wife if she:					Percentage who agree with at least one specified reason	Number of men
	Burns the food	Argues with him	Goes out without telling him	Neglects the children	Refuses to have sexual intercourse with him

Note: Total includes 18 men for whom information on employment in the past 12 months is missing.

Women's and men's attitudes towards wife beating have improved somewhat since the 2008-09 KDHS. In 2008-09, 53 percent of women and 44 percent of men agreed with wife beating for at least one of the specified reasons, compared with 42 percent of women and 36 percent of men in 2014.

15.7 WOMEN'S EMPOWERMENT INDICES

Women's empowerment has important implications for demographic and health outcomes, including women's use of family planning, maternal health care services, and child health. Two summary indices of women's empowerment were used to assess the relationship of selected demographic and health outcomes with women's empowerment.

The first index is the number of decisions that currently married women participate in alone or jointly with their husband/partner (see Table 15.6.1 for the list of decisions). The index ranges in value from 0 (participates in none of the four specified decisions) to 4 (participates in all four decisions). It reflects the degree of decision-making control that women are able to exercise in areas that affect their own lives and environments. A high score on this index suggests that women are more empowered in this domain. The second index ranges from 0 to 5 and corresponds with the total number of reasons for which women feel that a husband is justified in beating his wife (see Table 15.7.1 for the list of reasons). A low score on this index suggests that women have a greater sense of self-worth and higher status.

The relationship between the two indices is presented in Table 15.8. It is expected that women who participate more in making decisions at the household level will be less likely to endorse wife beating. The percentage of women who disagree with wife beating under any circumstance is highest among those who participate in 3-4 household decisions (60 percent). On the other hand, women who do not participate in any decisions and those who participate in one or two decisions have similar levels of support for wife beating (43 percent and 44 percent, respectively). It is also expected that women who more strongly endorse wife beating will be less likely to be involved in household decision making; however, there is no clear pattern between the number of reasons for which women justify wife beating and their participation in all four household decisions.

Table 15.8 Indicators of women's empowerment

Percentage of currently married women age 15-49 who participate in all decision making and the percentage who disagree with all of the reasons justifying wife beating, by value on each of the indicators of women's empowerment, Kenya 2014

Empowerment indicator	Percentage who participate in all decision making	Percentage who disagree with all the reasons justifying wife beating	Number of women
Number of decisions in which women participate[1]			
0	na	42.7	206
1-2	na	43.9	1,785
3-4	na	60.1	6,719
Number of reasons for which wife beating is justified[2]			
0	21.0	na	4,911
1-2	25.3	na	2,194
3-4	26.1	na	1,280
5	21.7	na	325

na = Not applicable
[1] See Table 15.6.1 for the list of decisions
[2] See Table 15.7.1 for the list of reasons

15.8 CURRENT USE OF CONTRACEPTION BY WOMEN'S STATUS

A woman's ability to have the number of children she wants and her use and choice of contraceptive methods are likely to be affected by self-image and sense of empowerment. A woman who feels that she is unable to control other aspects of her life may be less likely to feel she can make decisions regarding her fertility. She may also feel the need to choose contraceptive methods that are less obvious or do not need the approval or knowledge of her husband. Table 15.9 shows the relationship of each of the empowerment indices with current use of contraception among currently married women age 15-49, according to selected indicators of women's status.

Table 15.9 Current use of contraception by women's empowerment

Percent distribution of currently married women age 15-49 by current contraceptive method, according to selected indicators of women's status, Kenya 2014

Empowerment indicator	Any method	Modern methods				Any traditional method	Not currently using	Total	Number of women
		Any modern method	Female sterilisation	Temporary modern female methods[1]	Male condom				
Number of decisions in which women participate[2]									
0	37.8	35.5	1.3	32.8	1.5	2.2	62.2	100.0	206
1-2	54.9	51.4	2.6	47.2	1.6	3.5	45.1	100.0	1,785
3-4	59.5	54.4	3.5	48.4	2.5	5.1	40.5	100.0	6,719
Number of reasons for which wife beating is justified[3]									
0	60.2	55.9	3.3	49.8	2.9	4.3	39.8	100.0	4,911
1-2	57.7	52.3	3.4	47.5	1.4	5.4	42.3	100.0	2,194
3-4	52.3	47.5	3.3	42.3	1.9	4.8	47.7	100.0	1,280
5	49.5	44.8	1.8	42.3	0.6	4.7	50.5	100.0	325
Total	58.0	53.4	3.3	47.8	2.3	4.7	42.0	100.0	8,710

Note: If more than one method is used, only the most effective method is considered in this tabulation.
[1] Pill, IUD, injectables, implants, female condom and lactational amenorrhoea method
[2] See Table 15.6.1 for the list of decisions
[3] See Table 15.7.1 for the list of reasons

As may be expected, contraceptive use is positively associated with participation in household decision making and negatively associated with endorsement of wife beating. For example, the proportion of currently married women using a modern method of contraception increases from 36 percent among those not involved in any decision making to 54 percent among those involved in 3-4 decisions. Similarly, the proportion of currently married women using a modern method decreases from 56 percent among those who do not endorse wife beating to 45 percent among those who justify wife beating for all five specific reasons. These same patterns are generally observed for each of the individual contraceptive methods presented in Table 15.9.

15.9 IDEAL FAMILY SIZE AND UNMET NEED BY WOMEN'S STATUS

As a woman becomes more empowered, she is more likely to have a say in the number of children (ideal family size) she desires and the time at which she has them. She has more control over her ability to access and use contraceptives and to space and limit her family size. Women who have a desire to limit or delay their births, but who are not using family planning, are considered to have an unmet need for family planning. Table 15.10 shows how a woman's ideal family size and her unmet need for family planning vary by the two women's empowerment indices.

Table 15.10 Ideal number of children and unmet need for family planning by women's empowerment

Mean ideal number of children for women 15-49 and the percentage of currently married women age 15-49 with an unmet need for family planning, by indicators of women's empowerment, Kenya 2014

Empowerment indicator	Mean ideal number of children[1]	Number of women	Percentage of currently married women with an unmet need for family planning[2]			Number of women
			For spacing	For limiting	Total	
Number of decisions in which women participate[3]						
0	4.8	199	15.9	8.8	24.8	206
1-2	4.2	1,731	12.8	7.7	20.5	1,785
3-4	3.8	6,573	8.0	8.4	16.4	6,719
Number of reasons for which wife beating is justified[4]						
0	3.4	8,348	7.9	7.5	15.4	4,911
1-2	3.6	3,627	9.9	9.3	19.2	2,194
3-4	4.1	1,873	12.3	9.5	21.8	1,280
5	4.6	463	11.3	9.3	20.6	325
Total	3.6	14,311	9.2	8.3	17.5	8,710

[1] Mean excludes respondents who gave non-numeric responses.
[2] See Table 7.12 for the definition of unmet need for family planning
[3] Restricted to currently married women. See Table 15.6.1 for the list of decisions.
[4] See Table 15.7.1 for the list of reasons

As indicated in Table 15.10, mean ideal number of children varies with both indices of women's empowerment. The ideal number of children decreases as the number of decisions in which a woman participates increases, from 4.8 children among women who do not participate in any household decision making to 3.8 among women who participate in 3-4 household decisions. Ideal number of children increases with women's justification of wife beating.

With respect to need for family planning, women who score well on the first index, household decision making, are less likely to have an unmet need for spacing. Similarly, women who do not endorse wife beating are also less likely to have an unmet need for spacing. The relationship between the empowerment indicators and unmet need for limiting is mixed.

15.10 REPRODUCTIVE HEALTH CARE AND WOMEN'S EMPOWERMENT

Women's status is less likely to affect their access to health care services in places where such services are available. In other areas, increased empowerment of women is likely to enhance their ability to seek and use health care services that better meet their own reproductive health needs. Table 15.11 shows use of antenatal, delivery, and postnatal care services according to women's scores on the two empowerment indices. It is expected that empowered women will be more likely to seek out health care services that better meet their reproductive health goals, including safe motherhood.

Table 15.11 Reproductive health care by women's empowerment

Percentage of women age 15-49 with a live birth in the five years preceding the survey who received antenatal care, delivery assistance and postnatal care from health personnel for the most recent birth, by indicators of women's empowerment, Kenya 2014

Empowerment indicator	Percentage receiving antenatal care from a skilled provider[1]	Percentage receiving delivery care from a skilled provider[1]	Percentage of women with a postnatal checkup in the first two days after birth[2]	Number of women with a child born in the last five years
Number of decisions in which women participate[3]				
0	94.4	51.4	38.1	155
1-2	95.7	59.2	47.5	1,294
3-4	97.3	68.8	55.6	4,135
Number of reasons for which wife beating is justified[4]				
0	97.3	73.5	60.2	3,823
1-2	96.0	64.2	50.4	1,741
3-4	94.2	51.2	43.2	1,027
5	92.2	46.7	36.2	285
Total	96.3	66.7	54.2	6,876

[1] 'Skilled provider' includes doctor, nurse, or midwife.
[2] Includes women who received a postnatal checkup from a doctor, nurse, midwife, community health worker or traditional birth attendant (TBA) in the first two days after the birth. Includes women who gave birth in a health facility and those who did not give birth in a health facility.
[3] Restricted to currently married women. See Table 15.6.1 for the list of decisions.
[4] See Table 15.7.1 for the list of reasons

As expected, women's empowerment is positively associated with their access to and use of maternal health services. For example, the proportion of women who received delivery care from health personnel for a live birth in the five years before the survey increases with the number of decisions in which they participate, from 51 percent among those who do not participate in any decisions to 69 percent among those who participate in 3-4 decisions. Similar trends are seen between decision making and women's receipt of antenatal and postnatal care.

Among women who do not justify wife beating for any of the specified reasons, 97 percent received antenatal care, 74 percent received delivery care, and 60 percent received postnatal care within the first two days after delivery. In contrast, the corresponding proportions among women who justify wife beating for all five specified reasons were 92 percent, 47 percent, and 36 percent.

15.11 DIFFERENTIALS IN INFANT AND CHILD MORTALITY BY WOMEN'S STATUS

The ability of women to access information, make decisions, and act effectively in their own interests or in the interests of those who depend on them is essential to their empowerment. If women, the primary caretakers of children, are empowered, the health and survival of their children will be enhanced. In fact, maternal empowerment fits into Mosley and Chen's framework on child survival as an individual-level variable that affects child survival through proximate determinants (Mosley and Chen, 1984).

Table 15.12 presents infant and child mortality rates for the 10-year period preceding the survey, by indicators of women's empowerment. The results appear mixed and do not follow any discernible trend.

Table 15.12 Early childhood mortality rates by women's status

Infant, child, and under-5 mortality rates for the 10-year period preceding the survey, by indicators of women's empowerment, Kenya 2014

Empowerment indicator	Infant mortality ($_1q_0$)	Child mortality ($_4q_1$)	Under-5 mortality ($_5q_0$)

[2] See Table 15.7.1 for the list of reasons

DOMESTIC VIOLENCE 16

Robert C.B. Buluma, Rosemary Uside Kongani, John Wanyungu, Ruth Wayua Muia, Lawerence Ikamari

Key Findings

- Forty-five percent of women and 44 percent of men age 15-49 have experienced physical violence since age 15, and 20 percent and 12 percent, respectively, experienced physical violence within the 12 months prior to the survey. The main perpetrators of physical violence against women are husbands; whereas, the main perpetrators against men are parents, teachers, and others.
- Fourteen percent of women and 6 percent of men age 15-49 report having experienced sexual violence at least once in their lifetime.
- Overall, 39 percent of ever-married women and 9 percent of men age 15-49 report having experienced spousal physical or sexual violence.
- Among women and men who have ever experienced spousal violence (physical or sexual), 39 percent and 24 percent, respectively, reported experiencing physical injuries.
- Forty-four percent of women and 27 percent of men have sought assistance from any source to stop the violence they have experienced.

Since the 1990s, there has been an increased focus on violence against women in general, and domestic violence in particular, in both developed and developing countries. Not only has domestic violence been acknowledged worldwide as a violation of basic human rights, but an increasing amount of research continues to highlight the health burdens, intergenerational effects, and demographic consequences of such violence. Domestic violence occurs in all population subgroups. In many countries, including Kenya, women are often socialised into tolerating and rationalising a key component of domestic violence, namely violence by husbands against wives and to remain silent about it when it occurs. Violence of any kind has a detrimental impact on the economy of a country through increased disability, medical costs, and loss of labour hours; however, because women bear the brunt of domestic violence, they disproportionately bear the health and psychological burdens as well.

The Government of Kenya has enacted several laws and has policies and regulations to prevent and control various forms of violence against women and children including in the Constitution of Kenya (2010), the Sexual Offences Act (2006), the Children's Act (2001), the Penal Code (2009), the Prohibition of Female Genital Mutilation Act (2011), and the National Gender and Equality Commission Act (2011). In recognition of domestic violence as a serious problem in Kenya, the 2014 KDHS included the domestic violence module for both women and men.

16.1 MEASUREMENT OF VIOLENCE

The 2014 KDHS is the third DHS survey in Kenya to include questions on violence perpetrated against women and the first survey to include questions on violence against men. Collecting valid, reliable, and ethical data on domestic violence poses particular challenges. What constitutes violence or abuse varies across cultures and among individuals. A culture of silence usually surrounds domestic violence and can affect reporting. The sensitivity of the topic is another issue. Assuring the safety of respondents and interviewers when asking about domestic violence in a familial setting, protecting individuals who disclose

violence, and reducing the risk of double victimisation of respondents as they relive their experiences are all specific ethical concerns. The responses to these challenges in the 2014 KDHS are described in the sections that follow.

16.1.1 Use of Valid Measures of Violence

In the 2014 KDHS, information was obtained from ever-married respondents on violence committed by their current and former spouses and by others. Information was collected from never-married respondents on violence by anyone. Since international research shows that intimate partner violence is one of the most common forms of violence, especially against women, information on spousal violence was measured in more detail than violence by other perpetrators. This was done by using a shortened, modified version of the Conflict Tactics Scale (Strauss, 1990). Specifically, violence by the current spouse/partner for currently married respondents and by the most recent spouse/partner for formerly married respondents was measured by asking all ever-married women and men the following set of questions.

Does (did) your (last) spouse/partner ever:

(a) Push you, shake you, or throw something at you?

(b) Slap you?

(c) Twist your arm or pull your hair?

(d) Punch you with his/her fist or with something that could hurt you?

(e) Kick you, drag you, or beat you up?

(f) Try to choke you or burn you on purpose?

(g) Threaten or attack you with a knife, gun, or any other weapon?

(h) Physically force you to have sexual intercourse with him/her even when you did not want to?

(i) Physically force you to perform any other sexual acts you did not want to?

(j) Force you with threats or in any other way to perform sexual acts you did not want to?

For every question to which the respondent answered 'yes,' she or he was asked about the frequency of the act in the 12 months preceding the survey. An affirmative answer to one or more of items (a) to (g) above constitutes evidence of physical violence, and an affirmative answer to item (h) to (j) constitutes evidence of sexual violence.

Similarly, emotional violence among ever-married respondents was measured by the following questions.

Does (did) your (last) spouse/partner ever:

(a) Say or do something to humiliate you in front of others?

(b) Threaten to hurt or harm you or someone close to you?

(c) Insult you or make you feel bad about yourself?

This approach of asking about specific acts to measure violence has the advantage of not being affected by different understandings of what constitutes a summary term such as 'violence.' By including a wide range of acts, this approach has the additional advantage of giving the respondent multiple opportunities to disclose any experience of violence.

In addition to these questions that were asked only of ever-married respondents, all women and men were asked about physical violence from persons other than the current or most recent spouse/partner. Respondents who answered yes to this question were asked who committed violence against them and the frequency of such violence during the 12 months preceding the survey. Respondents who reported experiencing different forms of violence were asked for the perpetrators of the violence.

Although this approach to questioning is generally considered to be optimal, the possibility of underreporting of violence, particularly sexual violence, cannot be entirely ruled out in any survey, and this survey is no exception.

16.1.2 Ethical Considerations in the 2014 KDHS

In recognition of the challenges in collecting data on violence, the interviewers in the 2014 KDHS were given special training. The training focused on how to ask sensitive questions, ensure privacy, and build rapport between interviewer and respondent. Rapport with the interviewer, confidentiality, and privacy are all keys to building respondents' trust so that they can safely share their experiences with the interviewer. Also, placement of questions about violence at the end of the questionnaire provides time for the interviewer to develop a certain degree of rapport that should further encourage respondents to share their experiences of violence, if any. In addition, the following protections were built into the survey in keeping with the World Health Organization's ethical and safety recommendations for research on domestic violence (WHO, 2001).

- To maintain confidentiality, only one woman or man per household was administered the questions on violence. In the one-third of the households selected for the male survey, one man per household was randomly selected to receive the questions on domestic violence. In the remaining two-thirds of households, one woman per household was selected for the questions on violence. The random selection of one woman or man was done through a simple selection procedure based on the Kish grid, which was built into the Household Questionnaire (Kish, 1965).

- As a means of obtaining additional consent beyond the initial consent at the start of the interview, the respondent was informed at the start of the domestic violence module that the questions could be sensitive and was reassured regarding the confidentiality of her/his responses.

- The violence module was implemented only if privacy could be obtained. The interviewers were instructed to skip the module, thank the respondent, and end the interview if they could not maintain privacy.

- A brochure that included information on domestic violence and contact information for service centres across the country was provided to all eligible respondents after the interview was completed, irrespective of whether or not they were selected for the module. This was done to safeguard against identifying the respondent selected for the module and to provide information to all respondents so that they could access the services and be informed about what to do in the event of domestic violence.

16.1.3 Subsample for the Violence Module

The domestic violence module for women and the module for men were implemented in separate subsamples of households. Furthermore, in keeping with ethical requirements, only one woman or man per household was selected for the module, as mentioned above. As a result of these restrictions, a total of 5,657 women age 15-49 (4,023 ever-married women) and 4,962 men age 15-54 (2,890 ever-married men) completed the domestic violence module. In all, four women and four men eligible for the domestic violence module could not be interviewed with the module because privacy was not possible, and another 11 women and 29 men could not be interviewed with module due to other reasons.

16.2 Experience of Physical Violence

Tables 16.1.1 and 16.1.2 show the percentage of women and men age 15-49, respectively, who have experienced physical violence since age 15 and the percentage who have experienced violence during the 12 months preceding the survey, by background characteristics. Forty-five percent of women and 44 percent of men age 15-49 have experienced physical violence since age 15, and 20 percent of women and 12 percent of men experienced physical violence in the 12 months prior to the survey including 5 percent of women

and 2 percent of men, respectively, who reported that they had experienced physical violence often in the past 12 months.

Table 16.1.1 Experience of physical violence: Women

Note: Total includes one man for whom information on religion is missing and two men for whom information on employment is missing. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.

[1] Includes violence in the past 12 months. For men who were married before age 15 and who reported physical violence by a spouse, the violence could have occurred before age 15.

[2] Includes men for whom frequency in the past 12 months is not known.

The experience of physical violence differs by background characteristics. It increases by age from 32 percent among women age 15-19 to 52 percent among those age 40-49. The percentage is highest among women who are Roman Catholic or Protestant/other Christian (45-46 percent), women in Nyanza region (57 percent), women with three or more children (52-54 percent), and women who are employed (49-50 percent). Currently married (47 percent) and formerly married (64 percent) women are much more likely than those

who have never been married (32 percent) to have experienced physical violence. The percentage of women who have experienced physical violence since age 15 is higher among those with an incomplete or complete primary education (48-51 percent) and lower among those with no education (38 percent). There are no clear patterns by wealth; however, women in the highest wealth quintile are less likely to have experienced physical violence since age 15 (36 percent) than women in the lower quintiles (43-51 percent).

Men who are Roman Catholic or Protestant/other Christian (44-47 percent), men with five or more children (48 percent), and formerly married men (58 percent) are more likely to have experienced physical violence since age 15 than men in most other subgroups. While women's experience of physical violence since age 15 does not differ by residence, men in rural areas (47 percent) are more likely than men in urban areas (39 percent) to have experienced physical violence. By region, the percentage of men who have experienced physical violence since age 15 is lowest among those in North Eastern region (32 percent) and highest among those in Western region (61 percent). Men with no education (34 percent) and those in the highest wealth quintile (36 percent) are less likely than their counterparts in other subgroups to have experienced physical violence since age 15.

The percentage of women who experienced physical violence in the past 12 months (often or sometimes) also varies by background characteristics. It is highest among women age 25-39 (22-23 percent), women who report having no religion (27 percent), women living in rural areas (22 percent), women in Nyanza (30 percent), currently or previously married women (24-25 percent), women with three or more children (25-26 percent), and women who are employed (22-24 percent). Women with a secondary or higher education (16 percent) and those in the highest wealth quintile (14 percent) are less likely to have experienced physical violence in the past 12 months than most other women.

Men age 15-19 (24 percent), men living in Nyanza (15 percent), formerly married men (18 percent), men with no children (15 percent), men who are not employed (21 percent), men with an incomplete primary education (15 percent), and men in the second wealth quintile (16 percent) are more likely to have experienced physical violence in the past 12 months than other subgroups of men.

16.3 PERPETRATORS OF PHYSICAL VIOLENCE

Tables 16.2.1 and 16.2.2 show perpetrators of physical violence, according to marital status, among women and men age 15-49 who have experienced physical violence since age 15. These tables show that, although the percentages of women and men who report experiencing physical violence since age 15 are very similar, the persons perpetrating the violence differs greatly by gender for ever-married respondents.

Among ever-married women, the most commonly reported perpetrator of physical violence is the current husband or partner (57 percent) followed by the former husband/partner (24 percent). By contrast, among ever-married men, the most common perpetrators are those in the "other" category (46 percent), followed by teachers (29 percent). Only about 1 in 10 men who have experienced physical violence since age 15 mention their current spouse as a perpetrator of physical violence.

Among the never-married respondents reported perpetrators are similar for women and men. Among never-married women who have experienced physical violence since age 15, the most common perpetrators are teachers (48 percent), followed by mothers or stepmothers (40 percent) and fathers or stepfathers (19 percent). Among never-married men, the most commonly reported perpetrators are also teachers (46 percent), followed by those in the "other" category (39 percent), and fathers or stepfathers (21 percent).

16.4 EXPERIENCE OF SEXUAL VIOLENCE

Tables 16.3.1 and 16.3.2 show the percentage of women and men age 15-49, respectively, who have experienced sexual violence ever and in the past 12 months, according to background characteristics.

Table 16.3.1 shows that 14 percent of women age 15-49 have ever experienced sexual violence and 8 percent have experienced sexual violence in the past 12 months. There are notable variations in the experience of sexual violence by age. The youngest women (age 15-19) are less likely than older women age 30-49 to report sexual violence ever and in the past 12 months (7 percent and 3 percent, compared with 17-18 percent, respectively). Women's report of sexual violence is also lowest, at 6 percent or less, among Muslim, North Eastern, and never married women. The percentages of women who have experienced sexual violence ever and in the past year is lower among those with a secondary or higher education (10 percent and 5 percent, respectively) and those in the highest wealth quintile (11 percent and 6 percent, respectively) than other women in these categories.

Note: Total includes one man for whom information on religion is missing and two men for whom information on employment is missing. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] Includes violence in the past 12 months

Experience of sexual violence ever and in the past 12 months is highest among formerly married women (28 percent and 12 percent, respectively), women who are employed for cash (17 percent and 10 percent, respectively), Western, Nyanza and Nairobi women (20-22 percent and 12-14 percent), and women with three or more living children (19 percent and 10-11 percent, respectively).

Table 16.3.2 shows that 6 percent of men age 15-49 have ever experienced sexual violence and that 2 percent experienced sexual violence in the past 12 months. Men age 25-40 are more likely than younger or older men to report sexual violence. Sexual violence is highest at 17 percent ever and 7 percent in the past 12 months among formerly married men.

16.5 PERPETRATORS OF SEXUAL VIOLENCE

Tables 16.4.1 and 16.4.2 show perpetrators of sexual violence, according to marital status, among women and men age 15-49 who have ever experienced sexual violence.

Among ever-married women and men, the most commonly reported perpetrators of sexual violence are current spouses/partners (55 percent and 37 percent, respectively) and former spouses/partners (28 percent and 25 percent, respectively).

Among never-married women who have ever experienced sexual violence, the most common perpetrators of violence are strangers (reported by 44 percent of women), followed by friends or acquaintances (14 percent) and those in the "other" category (12 percent). Among never-married men, the most common perpetrators of sexual violence are those in the "other" category (reported by 42 percent of men), friends or acquaintances (19 percent), and strangers and other relatives (12 percent and 11 percent, respectively).

Table 16.4.1 Persons committing sexual violence: Women

16.6 AGE AT FIRST EXPERIENCE OF SEXUAL VIOLENCE

Tables 16.5.1 and 16.5.2 show the percentage of women and men age 15-49, respectively, who experienced sexual violence by specific exact ages, according to current age and current marital status. Four percent of women and 2 percent of men had experienced violence by age 18, including 2 percent of women and 1 percent of men who had experienced sexual violence by age 15. Overall, of those who reported sexual violence about half of women and men had first experienced sexual violence by age 22.

Table 16.5.1 Age at first experience of sexual violence: Women

Percentage of women age 15-49 who experienced sexual violence by specific exact ages, according to current age and current marital status, Kenya 2014

Background characteristic	Percentage who first experienced sexual violence by exact age:					Percentage who have not experienced sexual violence	Number of women

16.7 EXPERIENCE OF DIFFERENT FORMS OF VIOLENCE

Tables 16.6.1 and 16.6.2 present information on the experience of various forms of violence among respondents age 15-49.

Table 16.6.1 Experience of different forms of violence: Women

Percentage of women age 15-49 who have ever experienced different forms of violence by current age, Kenya 2014

Age	Physical violence only	Sexual violence only	Physical and sexual violence	Physical or sexual violence	Number of women
15-19	28.1	3.1	3.4	34.7	1,009
15-17	29.5	2.5	2.3	34.3	639

30-39	32.9	2.8	14.7	50.3	1,492
40-49	36.6	2.1	15.4	54.2	916
Total	33.3	2.6	11.5	47.4	5,657

Table 16.6.2 Experience of different forms of violence: Men

Percentage of men age 15-49 who have ever experienced different forms of violence by current age, Kenya 2014

Age	Physical violence only	Sexual violence only	Physical and sexual violence	Physical or sexual violence	Number of men
15-19	40.3	0.8	1.9	43.0	950
15-17	41.7	1.0	1.8	44.5	578
18-19	38.0	0.4	2.1	40.6	371
20-24	43.2	1.2	2.9	47.3	836
25-29	36.8	3.0	5.4	45.2	837
30-39	38.1	1.9	6.1	46.0	1,242
40-49	40.0	0.6	4.9	45.6	830
Total 15-49	39.5	1.5	4.4	45.4	4,694
50-54	39.6	0.2	6.5	46.4	268
Total 15-54	39.6	1.4	4.5	45.5	4,962

Forty-seven percent of women age 15-49 reported that they have experienced either physical or sexual violence. Thirty-three percent have experienced physical violence only, 3 percent have experienced sexual violence only, and 12 percent have experienced both physical and sexual violence. The percentage of women who have experienced physical or sexual violence increases steadily with age, from 35 percent among those age 15-19 to 54 percent among those age 40-49.

Overall, 45 percent of men age 15-49 reported that they have experienced either physical or sexual violence; 40 percent have experienced physical violence only, 2 percent have experienced sexual violence only, and 4 percent have experienced both physical and sexual violence. For men there are no clear relationships between age and the various forms of violence.

16.8 VIOLENCE DURING PREGNANCY

Female respondents who had ever been pregnant were asked specifically whether they had ever experienced physical violence while pregnant. Table 16.7 presents, among women age 15-49 who have ever been pregnant, the percentage who have ever experienced physical violence during pregnancy according to background characteristics.

Nine percent of ever-pregnant women have experienced physical violence during pregnancy. By age, this percentage is lowest among women age 15-19 (6 percent) and highest among women age 25-29 (11 percent). Physical violence during pregnancy is highest among women residing in Nairobi (18 percent, and formerly married women (21 percent).

Women with three or more children (10-11 percent), those with an incomplete primary education (12 percent), and those in the second or fourth wealth quintile (11 percent each) are more likely than other women in these categories to have experienced violence during pregnancy.

16.9 MARITAL CONTROL BY SPOUSE

Wives' or husbands' close control and monitoring of the behaviour of their spouse is known to be an important warning sign and correlate of violence in a relationship. A series of questions were included in the 2014 KDHS to elicit the degree of marital control exercised by husbands or wives over their spouses. Controlling behaviours most often manifest themselves in terms of extreme possessiveness, jealousy, and attempts to isolate spouses from their family and friends.

Table 16.7 Experience of violence during pregnancy

Among women age 15-49 who have ever been pregnant, percentage who have ever experienced physical violence during pregnancy, by background characteristics, Kenya 2014

Note: Total includes two women for whom information on religion is missing. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.

To determine degree of marital control, ever-married women and men were asked whether their current or former spouse exhibited each of the following controlling behaviours: (1) is jealous or gets angry if she/he talks to other men/women, (2) frequently accuses her/him of being unfaithful, (3) does not permit meetings with female/male friends, (4) tries to limit contact with her/his family, and (5) insists on knowing where she/he is at all times. Because the concentration of such behaviours is more noteworthy than the display of any single behaviour, the proportion of respondents whose spouses display at least three of the specified behaviours is highlighted. Tables 16.8.1 and 16.8.2 present the percentage of ever-married women and men age 15-49, respectively, whose spouses have ever displayed each of the listed behaviours, by selected background characteristics.

Table 16.8.1 Marital control exercised by husbands

Percentage of ever-married women age 15-49 whose husbands/partners have ever demonstrated specific types of controlling behaviours, by background characteristics, Kenya 2014

Background characteristic	Percentage of women whose husband/partner: Is jealous or angry if she talks to other men	Frequently accuses her of being unfaithful	Does not permit her to meet her female friends	Tries to limit her contact with her family	Insists on knowing where she is at all times	Displays 3 or more of the specific behaviours	Displays none of the specific behaviours	Number of ever-married women

Total 15-54	57.2	30.0	10.9	5.6	42.7	21.9	31.4	2,890

Note: Wife/partner refers to the current wife/partner for currently married men and the most recent wife/partner for divorced, separated or widowed men. Total includes one man for whom information on religion is missing, two men for whom information on employment is missing, and nine men for whom information on fear of wife/partner is missing. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.

The main controlling behaviours women experienced from their husbands were jealousy or anger if they talked to other men (53 percent) and insisting on knowing where they are at all times (41 percent). The next most common behaviours were husbands frequently accusing them of being unfaithful (23 percent) and not permitting them to meet female friends (21 percent).

Twenty-five percent of ever-married women say that their husbands display three or more of these controlling behaviours. Notably, among women who report being afraid of their husbands most of the time, the proportion who report that their husbands display three or more of these controlling behaviours is twice as high (53 percent) as the average for all ever-married women. About half of formerly married women also report that their former husband displayed three or more of these behaviours (48 percent). Women who report having no religion (31 percent), women living in the Coast and Nairobi regions (32-33 percent), women employed for cash (27 percent), and women with primary incomplete education (28 percent) are also more likely than most other women to have husbands who display three or more controlling behaviours.

Table 16.8.2 shows that, similar to women, the main controlling behaviours men experience from their wives were jealousy or anger if they talked to other women (58 percent) and insisting on knowing where they are at all times (43 percent). Thirty percent of men reported that their wives frequently accuse them of being unfaithful, and 11 percent said that their wives do not permit them to meet male friends.

Twenty-two percent of ever-married men say that their wives display three or more of these controlling behaviours. As with women, men who are afraid of their wives are much more likely to report controlling behaviours by their wives. Further, men reporting that their wives display three or more controlling behaviours is relatively high among men age 20-24 (33 percent), Christian men (22-23 percent), men living in the Coast and in Nyanza (29-30 percent), and formerly married men (42 percent). The percentage of men whose wives display at least three controlling behaviours is lowest among those with no education compared to those with some education (14 percent compared with 22-23 percent) and varies inconsistently by wealth.

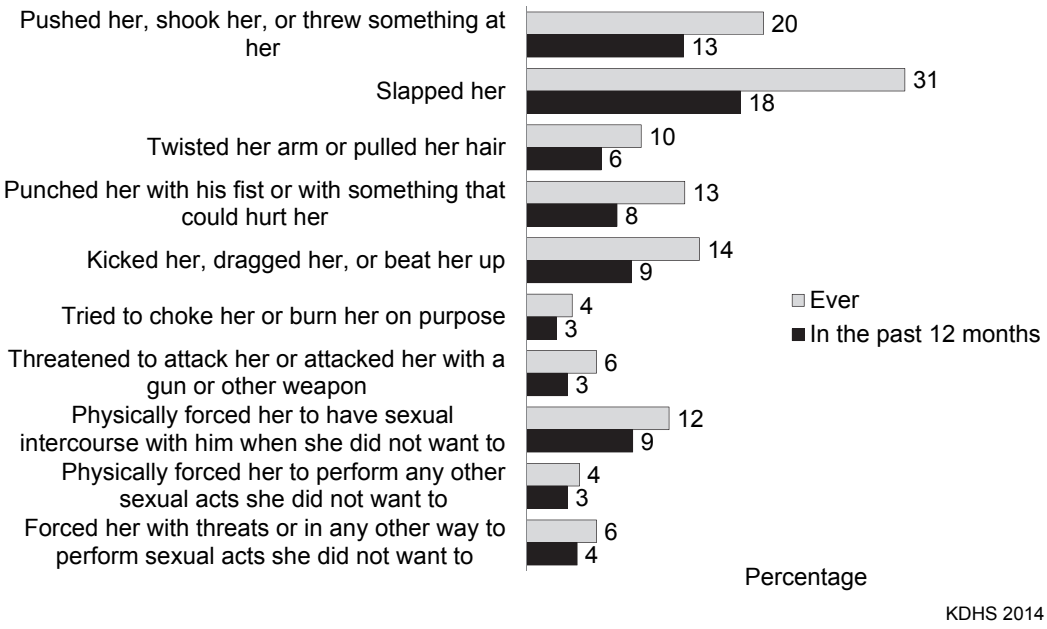
16.10 Forms of Spousal Violence

Different types of violence are not mutually exclusive, and people may report multiple forms of violence. Research suggests that physical violence in intimate relationships is often accompanied by psychological abuse and, in one-third to more than one-half of cases, by sexual abuse (Krug et al., 2002). Tables 16.9.1 and 16.9.2 show the percentage of ever-married women and ever-married men age 15-49, respectively, who have experienced various forms of violence by their spouse over the course of the marriage and in the 12 months preceding the survey. Note that respondents who are currently married reported on violence by their current spouse, and respondents who are widowed, divorced, or separated reported on violence by their most recent spouse.

Table 16.9.1 shows that 37 percent of ever-married women reported ever experiencing physical violence committed by their current or most recent husband or partner, 13 percent reported sexual violence, and 32 percent reported emotional violence. About 4 in 10 ever-married women (39 percent) have experienced physical and/or sexual violence, and slightly less than half (47 percent) have experienced at least one of the three forms of spousal violence.

Figure 6.1 shows the percentage of ever-married women reporting specific acts of physical or sexual violence perpetrated by their current or most recent husband. The most common form of spousal physical or sexual violence reported by ever-married women is being slapped (31 percent) followed by being pushed, shaken, or having something thrown at them. About equal percentages of women report experiencing being punched with his fist or something that could hurt her and being kicked dragged or beaten up (13-14 percent). The most common form of spousal sexual violence is being physically forced to have sex against her will.

Figure 16.1 **Percentage of ever-married women age 15-49 who have experienced specific types of spousal physical and sexual violence by the current or most recent husband/partner**



Specific acts of emotional violence are also quite common. Twenty-six percent of women reported that their husbands have insulted them or made them feel bad about themselves and 18 percent reported that their husband said or did something to humiliate them in front of others.

Twenty-three percent of ever-married women reported experiencing spousal physical violence in the past 12 months, with 7 percent having experienced it often during the period. Ten percent reported having experienced spousal sexual violence in the past 12 months (3 percent often). Additionally, 24 percent of women reported spousal emotional violence in the past 12 months (9 percent often). Overall, one-third (33 percent) of ever-married women experienced at least one of the three forms of violence by their current or most recent husband or partner in the past year.

Ever-married women who had been married more than once were also asked about physical or sexual violence by their earlier husband(s) or partner(s). Different forms of violence perpetrated by all husbands/partners is provided in the lower panel of Table 16.9.1. Overall, 38 percent of ever-married women have experienced physical violence by any husband ever and 14 percent have experienced sexual violence and 41 percent have experienced physical or sexual violence.

Table 16.9.1 Forms of spousal violence: Women

Percentage of ever-married women age 15-49 who have experienced various forms of violence ever or in the 12 months preceding the survey, committed by their husband/partner, Kenya 2014

Type of violence	Ever	In the past 12 months[1]		
		Often	Sometimes	Often or sometimes
SPOUSAL VIOLENCE COMMITTED BY CURRENT OR MOST RECENT HUSBAND/PARTNER				
Physical violence				
Any physical violence	36.9	6.7	15.9	22.6

Kicked her, dragged her, or beat her up	14.3	3.2	5.5	8.7
Tried to choke her or burn her on purpose	3.8	0.7	1.9	2.5
Threatened her or attacked her with a knife, gun, or other weapon	5.8	1.1	2.3	3.4
Sexual violence				
Any sexual violence	13.3	3.4	6.4	9.8
Physically forced her to have sexual intercourse with him when she did not want to	11.8	2.8	6.0	8.8
Physically forced her to perform any other sexual acts she did not want to	4.4	1.4	2.0	3.4
Forced her with threats or in any other way to perform sexual acts she did not want to	5.8	1.5	2.7	4.2
Emotional violence				
Any emotional violence	32.4	9.4	14.4	23.8
Said or did something to humiliate her in front of others	17.9	4.9	8.2	13.1
Threatened to hurt or harm her or someone she cared about	14.7	3.7	6.3	10.0
Insulted her or made her feel bad about herself	25.7	7.4	11.9	19.2
Any form of physical and/or sexual violence	39.4	7.9	17.5	25.4
Any form of emotional and/or physical and/or sexual violence	47.1	12.2	20.5	32.7
SPOUSAL VIOLENCE COMMITTED BY ANY HUSBAND/PARTNER				
Physical violence	38.4	na	na	22.7
Sexual violence	14.0	na	na	9.8
Physical and/or sexual violence	40.7	na	na	25.5
Number of ever-married women	4,023	4,023	4,023	4,023

[1] For widows, estimates of spousal violence by the current or most recent spouse in the past 12 months are not known; hence widows are excluded from the estimate of spousal violence by the current or most recent spouse in the past 12 months. However, widows are included in the estimate of spousal violence committed by any husband/partner in the past 12 months.
na = Not applicable

Table 16.9.2 shows that, among ever-married men, 7 percent reported ever experiencing physical violence by their current or most recent wife or partner, 4 percent reported sexual violence, and 21 percent reported emotional violence. About 1 in 10 men (9 percent) have ever experienced physical and/or sexual violence, and about 1 in 4 (24 percent) have experienced at least one of the three forms of spousal violence by their current or most recent wife or partner.

Table 16.9.2 Forms of spousal violence: Men

Percentage of ever-married men age 15-49 who have experienced various forms of violence ever or in the 12 months preceding the survey, committed by their wife/partner, Kenya 2014

However, widowers are included in the estimate of spousal violence committed by any wife/partner in the past 12 months.
na = Not applicable

Fifteen percent of ever-married men reported that their current or most recent spouse or partner ever insulted them or made them feel bad about themselves, and 13 percent reported that their wife or partner ever said or did something to humiliate them in front of others.

Five percent of ever-married men reported experiencing spousal physical violence in the past 12 months, with 1 percent having experienced it often. Three percent reported having experienced spousal sexual violence in the past 12 months (1 percent often). In addition, 15 percent of men reported emotional violence in the past 12 months (4 percent often). Overall, 18 percent of ever-married men have experienced at least one of the three forms of spousal violence by their current or most recent wife or partner in the past year.

About 1 in 10 men (11 percent) reported having ever experienced physical and/or sexual violence by any current or former wife or partner.

16.11 SPOUSAL VIOLENCE BY BACKGROUND CHARACTERISTICS

Tables 16.10.1 and 16.10.2 show the percentage of ever-married women and men age 15-49, respectively, who have experienced spousal emotional, physical, or sexual violence by selected background characteristics.

Table 16.10.1 Spousal violence by background characteristics: Women

Percentage of ever-married women age 15-49 who have ever experienced emotional, physical or sexual violence committed by their husband/partner, by background characteristics, Kenya 2014

Total 15-49	32.4	36.9	13.3	10.8	8.5	39.4	47.1	4,023

Note: Husband/partner refers to the current husband/partner for currently married women and the most recent husband/partner for divorced, separated or widowed women. Total includes one woman for whom information on religion is missing and two women for whom information on employment is missing. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.

Forty-seven percent of ever-married women have experienced at least one form of spousal violence (emotional, physical, or sexual) and 9 percent have experienced all three forms of violence.

The percentage of women who have experienced at least one form of spousal violence generally increases with age. It is higher among Christian women (48-49 percent) and lower among Muslim women (23 percent). By region, women in Western and Nairobi report the highest levels of violence (60 percent each). Those who are divorced, separated, or widowed (66 percent) more often report violence than any other

group of women. Women with no education are less likely to experience any form of violence (38 percent) than women in the other educational categories, even women who have completed secondary education (43 percent). Experience of at least one form of violence peaks among women in the second wealth quintile (53 percent) and is lower in other wealth quintiles.

Table 16.10.2 shows that 24 percent of ever-married men have experienced at least one form of spousal violence (emotional, physical, or sexual), and just 1 percent have experienced all three forms of violence. Notably, most of the spousal violence men report is in the form of emotional violence. Only 9 percent of ever-married men report spousal physical or sexual violence compared with 39 percent of ever-married women. Muslim men, men in the North Eastern region, and men with no education are less likely than other subgroups of men to report at least one form of spousal violence.

Table 16.10.2 Spousal violence by background characteristics: Men

Total 15-54	20.3	7.0	3.8	1.6	1.4	9.2	23.4	2,890

Note: Wife/partner refers to the current wife/partner for currently married men and the most recent wife/partner for divorced, separated or widowed men. Total includes five men for whom information about wife's/partner's alcohol consumption is missing or unknown, one missing spousal education difference, and nine missing fear of husband/partner. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] Includes only currently married men who have only one wife.
[2] According to the husband's report. See Table 16.8.2 for list of behaviours.
[3] According to the husband's report. Includes only currently married men. See Table 15.6.2 for list of decisions.
[4] According to the husband's report. See Table 15.7.2 for list of reasons.

Table 16.11.1 shows that, among ever-married women, spousal violence is higher among those whose husband has only a primary education (51 percent) and those who are better educated than their husband (52 percent). Although women whose husbands get drunk very often are much more likely (78 percent) to experience at least one form of spousal violence than women whose husbands do not drink, it is notable that even among the latter women, 38 percent report experiencing at least one form of violence.

Spousal violence increases with the number of controlling behaviours displayed by the husband. Among women whose husbands exhibit five types of controlling behaviours, more than 9 in 10 (91 percent) have experienced one or more forms of violence. In contrast, among women whose husbands display none of the five controlling behaviours, about one in four (24 percent) have experienced any form

of spousal violence. Women's experience of violence tends to decrease as the number of decisions in which they participate increases. Women's experience of violence increases with the number of reasons they agree with for which wife beating is justified. Women whose father beat their mother are much more likely to experience any type of violence by their husband than women whose father did not beat their mother (57 percent versus 40 percent). Finally, women who are never afraid of their husband/partner are much less likely to experience spousal violence than women who are afraid of him most of the time (34 percent versus 83 percent).

Table 16.11.2 shows similar patterns in spousal violence against ever-married men according to wives' characteristics. In many cases, the numbers are too small to reach meaningful conclusions. However, similar to women, spousal violence against men increases with the number of controlling behaviours displayed by the wife, from 8 percent among men whose wives/partners display none of the controlling behaviours to 72 percent among those whose wives/partners exhibit all five types of controlling behaviours. Men's experience of spousal violence generally increases as the number of reasons they agree with for which wife beating is justified increases. Men whose father did not beat their mother are less likely to experience any type of spousal violence than men whose father beat their mother (20 percent versus 28 percent). As expected, men who are never afraid of their wife/partner are less likely to experience spousal violence than other men.

16.13 RECENT SPOUSAL VIOLENCE

Tables 16.12.1 and 16.12.2 show the percentage of ever-married women and men age 15-49, respectively, who have experienced physical or sexual violence by any spouse/partner in the past 12 months, by background characteristics. For women and men who have been married more than once, these tables include violence by any previous spouse/partner.

Overall, 26 percent of women experienced physical or sexual violence by any husband or partner in the past 12 months. The percentage of women who have experienced recent physical or sexual violence by any spouse or partner is higher among those age 20-29 (28 percent), than among younger or older women. Muslim women (10 percent) are much less likely than Christian (26-27 percent) women or women with no religion (33 percent) to report any recent spousal violence. By region, violence is most common among women living in Western region (37 percent) and least common among women in the North Eastern region (6 percent). The percentage experiencing recent violence increases with number of living children.

Table 16.12.1 Physical or sexual violence in the past 12 months by any husband/partner: Women

Percentage of ever-married women who have experienced physical or sexual violence by any husband/partner in the past 12 months, by background characteristics, Kenya 2014

Woman afraid of husband/partner		
Most of the time afraid	50.4	495
Sometimes afraid	39.8	949
Never afraid	15.5	2,571
Total 15-49	25.5	4,023

Note: Any husband/partner includes all current, most recent and former husbands/partners. Total includes one woman for whom information on religion is missing, two women for whom information on employment is missing, and seven women for whom information on fear of husband/partner is missing. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.

Women with an incomplete primary education (31 percent), women in the bottom three wealth quintiles (27-30 percent), and women who are afraid of their husband/partner most of the time (50 percent) are more likely than most other women to have experienced physical or sexual violence by any husband or partner in the past 12 months.

Among ever-married men, 7 percent experienced physical or sexual violence in the past 12 months by any wife or partner. Men age 20-24 (12 percent), men living in Nairobi (11 percent), previously married men (16 percent), and men with no living children (10 percent) are more likely to have experienced recent physical or sexual violence by any spouse or partner. Similarly, men with an incomplete primary education (8 percent), those in the bottom three wealth quintiles (8 percent), and those who are afraid of their wife/partner sometimes (31 percent) are more likely than other men to have experienced physical or sexual violence from any wife or partner in the past 12 months.

16.14 ONSET OF SPOUSAL VIOLENCE

To obtain information on the onset of marital violence, the 2014 KDHS asked ever-married women and men who reported spousal violence when in their marriage the violence first occurred. Tables 16.13.1 and 16.13.2 show the timing of the first experience of violence by marital duration among currently married women and men age 15-49 who have been married only once, respectively.

Table 16.13.1 shows that 65 percent of currently married women married only once have never experienced spousal physical or sexual violence by their current husband, 11 percent experienced violence in the first two years of marriage, 24 percent experienced it in the first five years, and 30 percent experienced it within the first 10 years of marriage. Among women who have experienced spousal physical or sexual violence, about one-third first experienced it in the first two years of marriage.

Among currently married men who have been married only once, more than 9 in 10 (93 percent) have not experienced spousal physical or sexual violence by their current wife, 2 percent experienced violence in the first two years of marriage, 5 percent experienced it in the first five years, and 6 percent experienced it within the first 10 years of marriage (Table 16.13.2).

Table 16.12.2 Physical or sexual violence in the past 12 months by any wife/partner: Men

16.15 PHYSICAL CONSEQUENCES OF SPOUSAL VIOLENCE

In the 2014 KDHS, ever-married women and men who reported spousal violence were asked whether they had sustained some form of injury as a result of physical or sexual violence inflicted by their spouse. Tables 16.14.1 and 16.14.2 show the percentage of ever-married women and men age 15-49 who have experienced spousal violence by the types of injuries they suffered, according to the type of violence reported and whether they experienced the violence ever and in the last 12 months.

About one-third of women (32 percent) who reported ever having experienced spousal physical or sexual violence suffered cuts, bruises, or aches; 18 percent had eye injuries, sprains, dislocations, or burns; and 10 percent had deep wounds, broken bones, broken teeth, or other serious injuries (Table 16.14.1). Overall, 39 percent of women who had ever experienced spousal physical or sexual violence suffered one or more of these injuries. The prevalence of all forms of injury is slightly higher among women who experienced violence in the past 12 months.

Table 16.14.2 shows that, among men who reported ever having experienced spousal physical or sexual violence, about one in five (21 percent) suffered cuts, bruises, or aches; 9 percent had eye injuries, sprains, dislocations, or burns; and 5 percent had deep wounds, broken bones, broken teeth, or other serious injuries. Twenty-four percent of men who had ever experienced spousal physical or sexual violence suffered one or more of these injuries. Similar percentages of men who had experienced violence in the past 12 months suffered each of the above injuries.

Table 16.14.1 Injuries to women due to spousal violence: Women

Percentage of ever-married women age 15-49 who have experienced specific types of spousal violence by types of injuries resulting from the violence, according to the type of violence and whether they experienced the violence ever and in the 12 months preceding the survey, Kenya 2014

Type of violence	Cuts, bruises, or aches	Eye injuries, sprains, dislocations, or burns	Deep wounds, broken bones, broken teeth, or any other serious injury	Any of these injuries	Number of ever-married women who have ever experienced any physical or sexual violence
Experienced physical violence[1]					
Ever[2]	33.5	19.4	10.1	40.3	1,485
In the past 12 months	38.0	23.3	12.4	45.7	908

Experienced physical or sexual violence					
Ever[1]	20.7	8.8	5.0	24.1	247
In the past 12 months	22.2	9.7	6.1	25.7	187

Note: Wife/partner refers to the current wife/partner for currently married men and the most recent wife/partner for divorced, separated or widowed men.
[1] Includes in the past 12 months

16.16 VIOLENCE BY WOMEN AND MEN AGAINST THEIR SPOUSE

In cases of domestic violence, either person (husband or wife) can be the perpetrator of violence. In the 2014 KDHS, ever-married women and men were asked about instances when they were the instigator of spousal violence. Specifically, all eligible ever-married respondents were asked whether they had ever initiated physical violence against their spouse when he or she was not already hitting or beating the respondent.

Tables 16.15.1 and 16.15.2 show the percentage of ever-married women and men age 15-49, respectively, who reported initiating physical violence against their spouses ever and in the 12 months prior to the survey, by background characteristics.

Table 16.15.1 Women's violence against their spouse by background characteristics

Percentage of ever-married women age 15-49 who have committed physical violence against their current or most recent husband/partner when he was not already beating or physically hurting her, ever and in the past 12 months, according to women's own experience of spousal violence and background characteristics, Kenya 2014

Background characteristic	Percentage who have committed physical violence against their husband/partner		Number of ever-married women
	Ever[1]	In the past 12 months

Note: Wife/partner refers to the current wife/partner for currently married men and the most recent wife/partner for divorced, separated or widowed men. Total includes one man for whom information on religion is missing and two men for whom information on employment is missing. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] Includes in the past 12 months

Overall, 4 percent of ever-married women reported that they had initiated physical violence against their husbands, and 3 percent had done so in the past 12 months. Women who have been physically abused by their husband ever and in the past 12 months are more likely to have initiated spousal physical abuse (9 percent and 11 percent, respectively) than women who have never been abused (1 percent). Women's use of violence against their husbands does not vary notably by other background characteristics.

Table 16.15.2 shows that 37 percent of ever-married men age 15-49 reported having initiated physical violence against their wives, and 14 percent had done so in the past 12 months. Men who have been physically abused by their spouse ever and in the past 12 months are about twice as likely (69 percent each) as those who have never been abused (34 percent) to initiate physical violence against their wives. Men age 40-49 (42 percent), Christian men (37-39 percent), men in Nyanza (59 percent), previously married men (48 percent), men with five or more living children (50 percent), men with an incomplete primary education (43 percent), and men in the second wealth quintile (45 percent) are most likely to have initiated physical violence against their wife or partner. There are similar variations by background characteristics in the percentage of ever-married men who reported that they had initiated physical violence against their wives in the past 12 months.

16.17 Violence against Spouses by Spousal Characteristics and Women's Empowerment Indicators

Tables 16.16.1 and 16.16.2 present information on ever-married women and men age 15-49, respectively, who have committed physical violence against their spouse ever and in the past 12 months, according to spousal characteristics and empowerment indicators.

Table 16.16.1 shows that women whose husband gets drunk very often (10 percent), women whose husband displays five controlling behaviours (13 percent), and women who are afraid of their husband/partner most of the time (9 percent) are most likely to have committed physical violence against their spouse. Similar variations by background characteristics are observed in women's physical violence against their spouse in the past 12 months.

Table 16.16.2 shows that men whose wife gets drunk sometimes (52 percent) are most likely to have committed violence against their spouse. The percentage of men who have committed violence against their spouse increases steadily as the number of controlling behaviours displayed by the wife increases. Twenty-four percent of men whose wife displays none of the six controlling behaviours have initiated physical violence against their spouse, as compared with 60 percent of men whose wife exhibits five controlling behaviours. The percentage of men who initiate physical violence against their spouse is lowest among those who do not agree with any of the reasons that justify wife beating. Men whose father did not beat their mother are much less likely to commit physical violence against their spouse than men whose father beat their mother (30 percent versus 44 percent). Similar to women, men who are afraid of their wife/partner sometimes (58 percent) are much more likely than men who are not afraid to commit physical violence against their spouse.

Table 16.16.1 Women's violence against their spouse by spouse's characteristics and empowerment indicators

Percentage of ever-married women age 15-49 who have committed physical violence against their current or most recent husband/partner when he was not already beating or physically hurting her, ever and in the past 12 months, according their husband's characteristics, Kenya 2014

16.18 HELP-SEEKING BEHAVIOUR BY WOMEN AND MEN WHO EXPERIENCE VIOLENCE

Tables 16.17.1 and 16.17.2 show the percent distribution of women and men age 15-49 who have ever experienced physical or sexual violence committed by anyone, respectively, according to whether they ever sought help to stop the violence and, among those who did not seek help, whether or not they told anyone about the violence.

Table 16.17.1 Help seeking to stop violence: Women

Percent distribution of women age 15-49 who have ever experienced physical or sexual violence by their help-seeking behaviour by type of violence and background characteristics, Kenya 2014

Note: Total includes one man for whom information on religion is missing and two men for whom information on employment is missing. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.

Overall, more than 4 in 10 women (44 percent) who have experienced any type of physical or sexual violence from anyone sought help from any source to stop the violence. A similar proportion (41 percent) never sought help and never told anyone, and 11 percent never sought help but told someone.

Women who have experienced both physical and sexual violence (59 percent), women age 30-49 (49 percent), women who report having no religion (66 percent), women in rural areas (46 percent), and women in Eastern region (54 percent) are more likely than other women to seek help to stop violence. A much higher proportion of divorced, separated, or widowed women (61 percent) than never-married women (34 percent) and currently married women (43 percent) have ever sought help. Help seeking increases with number of living children, from 34 percent among women with no living children to 52 percent among those with five or more children. Unemployed women (34 percent), those with no education (34 percent), and those in the highest wealth quintile (38 percent) are less likely than other women to seek help from any source to stop the violence.

Among ever-married men who have experienced any type of physical or sexual violence from anyone, 27 percent sought help from any source to stop the violence. Forty-six percent never sought help and never told anyone, and 20 percent never sought help but told someone. The observed patterns in help seeking among men by background characteristics are similar to those among women.

Tables 16.18.1 and 16.18.2 show the percentage of women and men age 15-49, respectively, who experienced physical or sexual violence and sought help by the sources from which help was sought. The most common sources of help among women are their own family (65 percent), their husband's or partner's family (31 percent), others (12 percent), neighbours (9 percent), and friends (8 percent). Among men, the most common sources are their own family (49 percent), the police (19 percent), others (17 percent), friends (14 percent), and doctors/medical personnel (13 percent).

Table 16.18.1 Sources for help to stop the violence: Women

Percentage of women age 15-49 who have experienced physical or sexual violence and sought help by sources from which they sought help, according to the type of violence that women reported, Kenya 2014

	Type of violence experienced			
Person	Physical only	Sexual only	Physical and sexual	Total
Own family	66.4	(76.2)	59.3	64.6
Husband/partner's family	31.4	(14.9)	31.8	30.8
Husband/partner	0.8	(0.0)	2.5	1.3

ADULT AND MATERNAL MORTALITY 17

Alfred Agwanda, John Anampiu, Andrew A. Imbwaga

Key Findings

- Fourteen percent of women and 18 percent of men are likely to die between exact ages 15 and 50.
- Maternal deaths account for 14 percent of all deaths to women age 15-49.
- The maternal mortality ratio was 362 maternal deaths per 100,000 live births for the seven-year period preceding the survey.
- When comparing the estimate of an MMR of 362 with the MMR estimated in the previous KDHS (2008-09 KDHS estimate of 520 maternal deaths per 100,000 live births), the differential is not large enough to conclude whether or not there has been any change over time between the two surveys.

Adult and maternal mortality rates are key indicators of the health status of a population. They are also national development indicators. Moreover, levels and trends in overall adult mortality have important implications for health and social programmes in Kenya in their own right, especially with regard to the potential impact of the AIDS epidemic, other infectious diseases, and noncommunicable diseases. Estimation of these mortality rates requires comprehensive and accurate reporting of adult deaths. This chapter includes results based on sibling history data collected in Section 11 of the 2014 KDHS Woman's Questionnaire.

In addition to adult mortality rates for five-year age groups, this chapter includes a summary measure ($_{35}q_{15}$) that represents the probability of dying between exact ages 15 and 50. To allow for assessment of trends in adult mortality probabilities, $_{35}q_{15}$ values were also calculated from the 2003 and 2008-09 KDHS survey data.

17.1 DATA AND ASSESSMENT OF QUALITY

To obtain a sibling history, the 2014 KDHS first asked each female respondent to list all children born to her biological mother, starting with the firstborn. The survey then asked the respondent whether each of these siblings was still alive. For living siblings, the questionnaire asked the current age of each sibling. For deceased siblings, the age at death and the number of years since death were recorded. When a respondent could not provide precise information on age at death or years since death, approximate but quantitative answers were accepted. For sisters who died at age 12 or older, the KDHS asked three questions to determine whether the death was maternal: 'Was [NAME OF SISTER] pregnant when she died?' and, if the response was negative, 'Did she die during childbirth?' and, if negative again, 'Did she die within two months after the end of a pregnancy or childbirth?'

Table C.8 in Appendix C shows that, in the 2014 KDHS, a total of 84,613 siblings were recorded in the sibling histories. The survival status was not reported for 39 siblings. Among surviving siblings, current age was not reported for 305 siblings (0.4 percent). Ninety-eight percent of deceased siblings had both age at death (AD) and years since death (YSD) reported. In less than 1 percent of cases, both age at death and years since death were missing. The sex ratio of the enumerated siblings (the ratio of brothers to sisters multiplied by 100) is 100.2 (Table C.9), which is slightly lower than the expected value of 102-106. Indicators of data quality for the 2014 KDHS show some improvement compared with the 2008-09 KDHS.

17.2 ESTIMATES OF ADULT MORTALITY

One way to assess the quality of data used to estimate maternal mortality is to evaluate the plausibility and stability of overall adult mortality estimates over a given time period. If the estimated rates of overall adult mortality are implausible, rates based on a subset of deaths—maternal mortality in particular—are likely to be unreliable.

The direct estimation of adult mortality uses the reported ages at death and years since death of the respondents' brothers and sisters. Mortality rates are calculated by dividing the number of deaths in each age group of women and men by the total person-years of exposure to the risk of dying in that age group during a specified period prior to the survey. To have a sufficiently large number of adult deaths to generate a robust estimate, the rates are calculated for the seven-year period preceding the survey. It should be noted that age-specific mortality rates obtained in this manner are subject to considerable sampling variation.

Table 17.1 Adult mortality rates

Direct estimates of female and male mortality rates for the seven years preceding the survey, by five-year age groups, Kenya 2014

Age	Deaths	Exposure years	Mortality rates[1]
FEMALE			
15-19	54	32,170	1.67
20-24	85	40,528	2.10
25-29	105	39,466	2.66
30-34	158	33,397	4.73
35-39	174	25,719	6.78
40-44	119	17,486	6.83
45-49	55	10,965	5.00
15-49	750	199,731	3.72[a]
MALE			
15-19	66	32,206	2.05
20-24	93	39,368	2.36
25-29	141	38,953	3.62
30-34	175	33,478	5.23
35-39	179	25,185	7.11
40-44	165	16,990	9.71
45-49	110	10,622	10.39
15-49	929	196,802	4.78[a]

[1] Expressed per 1,000 population
[a] Age-adjusted rate

The confidence intervals for adult mortality rates are presented in Appendix Table B.13. When calculating confidence intervals (CIs), we assume the sample from which the estimate is drawn follows a normal distribution. When comparing point estimates between two surveys and calculating CIs to determine whether or not the difference is statistically significant, we assume the sample from which each estimate was calculated follows a normal distribution and that the two samples are independent. Thus when comparing mortality estimates, for example, we can refer to the CI when gauging whether the difference between two surveys estimates within sex and within an age group, but we cannot gauge statistical significance of differences across sex within the same survey, or across age groups within the same survey, because the assumption of independence within the survey is violated.

Table 17.1 shows age-specific mortality rates for women and men age 15-49 for the seven-year period preceding the survey. The age-specific rates generally show the expected pattern of increasing mortality with increasing age. Overall, the estimated level of adult mortality is slightly higher among men (4.78 deaths per 1,000 population) than among women (3.72 deaths per 1,000 population). The overall rate for ages 15-49 were standardised by the age distribution of the survey respondents to remove the effect of truncation bias (the upper boundary for eligibility for women interviewed in the KDHS was 49 years and 54 years for men).

Table 17.2 shows trends in the summary measure of the risk of dying between exact ages 15 and 50 ($_{35}q_{15}$). According to data from the 2014 KDHS, 14 percent of women and 18 percent of men are likely to die between age 15 and age 50 if the prevailing mortality probabilities continue to apply. Estimates of $_{35}q_{15}$ calculated from the 2003, 2008-09, and 2014 KDHS surveys show that the probability of dying sometime between exact ages 15 and 50 has been declining. Confidence intervals for the $_{35}q_{15}$ estimates from all three surveys can be found in Appendix Table B.13. Note that the surveys did not detect a significant change between the 2003 and 2008-09 surveys; the 2014 survey has detected a fall in the probability of dying between age 15 and 50 has occurred over the previous seven years among men and women.

Table 17.2 Adult mortality probabilities

The probability of dying between the ages of 15 and 50 for women and men for the seven years preceding the survey, Kenya 2014

Survey	Female $_{35}q_{15}$[1]	Male $_{35}q_{15}$[1]
2014 KDHS	138	183
2008-09 KDHS	214	231
2003 KDHS	235	240

[1] The probability of dying between exact ages 15 and 50, expressed per 1,000 person-years of exposure

17.3 ESTIMATES OF MATERNAL MORTALITY

Two procedures involving sisterhood data (sibling history data) are generally used to estimate maternal mortality in developing countries; these procedures employ an indirect variant (Graham et al., 1989) and a direct estimation method (Rutenberg et al., 1991). In this report, the direct estimation procedure is applied. Age-specific mortality rates are calculated by dividing the number of maternal deaths by woman-years of exposure. As was done in the calculation of adult mortality rates, the overall rate for women age 15-49 is standardised by the age distribution of the survey respondents.

Table 17.3 presents direct estimates of maternal mortality for the seven-year period preceding the survey. Maternal deaths represent about 14 percent of all deaths among women age 15-49. The percentage of female deaths that are maternal varies by age from about 5 percent among women age 45-49 to 27 percent among women age 25-29.

Table 17.3 Maternal mortality

Direct estimates of maternal mortality rates for the seven years preceding the survey, by five-year age groups, Kenya 2014

Age	Percentage of female deaths that are maternal	Maternal deaths	Exposure years	Maternal mortality rate[1]
15-19	6.8	4	32,170	0.11
20-24	21.8	19	40,528	0.46
25-29	27.4	29	39,466	0.73
30-34	13.7	22	33,397	0.65
35-39	12.8	22	25,719	0.87
40-44	7.3	9	17,486	0.50
45-49	4.5	2	10,965	0.22
15-49	14.1	106	199,731	0.51

General fertility rate (GFR)[2]	142[a]
Maternal mortality ratio (MMR)[3]	362 CI: (254, 471)
Lifetime risk of maternal death[4]	0.015

CI: Confidence interval
[1] Expressed per 1,000 woman-years of exposure
[2] Expressed per 1,000 woman age 15-49
[3] Expressed per 100,000 live births; calculated as the age-adjusted maternal mortality rate times 100 divided by the age-adjusted general fertility rate
[4] Calculated as $1-(1-MMR)^{TFR}$ where TFR represents the total fertility rate for the seven years preceding the survey
[a] Age-adjusted rate

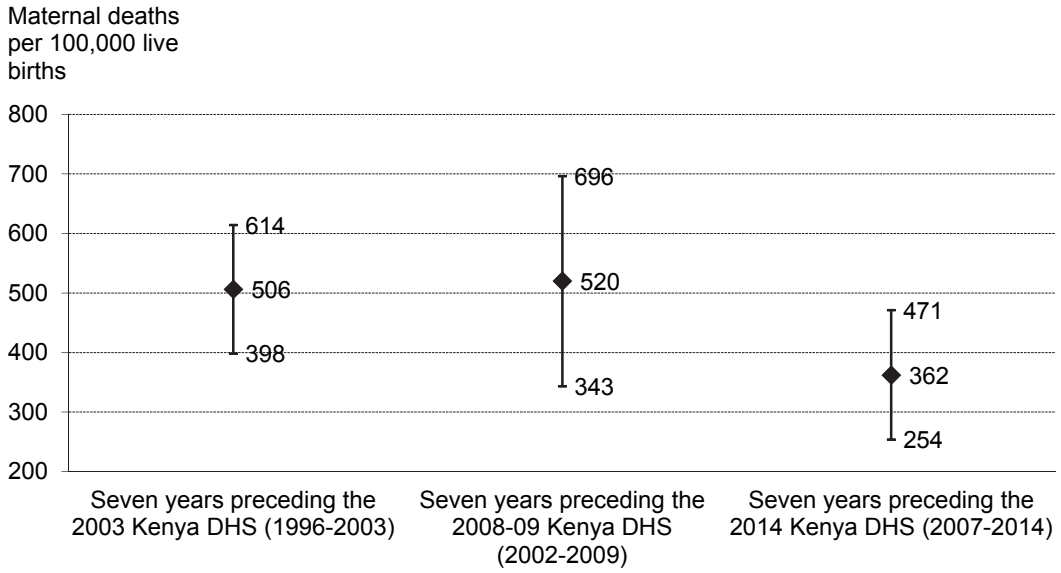
The data indicate that the rate of mortality associated with pregnancy and childbearing is 0.51 maternal deaths per 1,000 woman-years of exposure. The estimated age-specific maternal mortality rates display a generally plausible pattern, being higher at the peak childbearing ages (20s and 30s) than in the younger and older age groups. By five-year age groups, the maternal mortality rate is highest among women age 35-39 (0.87), followed by those age 25-29 (0.73).

The maternal mortality rate can be converted to a maternal mortality ratio (expressed as deaths per 100,000 live births) by dividing the maternal mortality rate by the general fertility rate (GFR) of 142 that prevailed during the same time period and multiplying the result by 100,000. This procedure produces a maternal mortality ratio (MMR) of 362 deaths per 100,000 live births during the seven-year period preceding the survey. In other words, for every 1,000 live births in Kenya in the seven years preceding the 2014 KDHS, approximately four women died during pregnancy, during childbirth, or within two months of childbirth. The lifetime risk of maternal death (0.015) indicates that approximately 2 percent of women, or about 1 in 67, will have a maternal death (i.e., they will die during pregnancy, during childbirth, or within two months of childbirth).

In order to compare maternal mortality estimates for the 2014 KDHS with previous estimates, the maternal mortality ratio for the seven years prior to the survey was re-calculated with data from the 2003 KDHS and the 2008-09 KDHS. As shown in Figure 17.1, the confidence intervals surrounding the 2003

point estimate are completely encompassed by the confidence interval surrounding the 2008-09 estimate, concluding that maternal mortality did not change significantly in the period 1996-2009. However, the confidence intervals surrounding the estimates around the 2008-09 (CI: 343, 696) and 2014 (CI:254, 471) estimates overlap, such that the estimate of 362 deaths per 1,000 population (2014 KDHS) is encompassed within the 2008-09 confidence interval, but the 2008-09 estimate (520 deaths per 1,000 population) is not encompassed within the 2014 confidence interval. Thus we conclude that the survey has not detected a change between the two surveys. However, there could be a change that was too small to be detected by the survey. Even with their large sample sizes, DHS surveys are able to detect only very large changes in the maternal mortality ratio.

Figure 17.1 **Maternal mortality ratio (MMR) with confidence intervals for the seven years preceding the KDHS**



FEMALE GENITAL CUTTING 18

Rosemary Uside Kongani, Robert C.B. Buluma, Lawrence Ikamari

Key Findings

- Twenty-one percent of women age 15-49 have been circumcised.
- There is some evidence of a trend over time to circumcise girls at younger ages. Twenty-eight percent of circumcised women age 20-24 were circumcised at age 5-9, as compared with 17 percent of circumcised women age 45-49.
- With respect to type of circumcision, 2 percent of circumcised women age 15-49 had cutting with no flesh removed, 87 percent had cutting with flesh removed, and 9 percent had their genital area sewn closed after cutting (a procedure known as infibulation).
- Girls age 0-14 are more likely to be circumcised if their mother is circumcised. Likewise, girls age 0-14 are more likely to be infibulated if their mother is also infibulated.
- Eight percent of girls age 0-14 have had their genital area sewn closed.
- Eleven percent or less of women and men believe that the practice of female genital cutting is required by their community or their religion or that the practice should continue.

Female genital cutting (FGC)—also called female circumcision and female genital mutilation—involves cutting some part of the clitoris or labia for non-therapeutic reasons, usually as part of a rite of passage into adolescence. It is practiced by some ethnic groups in Kenya as well as in other East African countries and is motivated by beliefs about what is considered proper sexual behaviour for women and what is necessary to prepare them for marriage (WHO, 2014b). However, the practice is widely acknowledged as a violation of children and women's rights, and it has the potential to cause serious medical complications. In 2011, Kenya passed a law—the Prohibition of Female Genital Mutilation Act 2011—that banned female genital mutilation nationwide. Under this law, it is illegal to practice FGC in Kenya or to take someone abroad for FGC.

The 2014 KDHS collected information about FGC in Kenya from women and men age 15-49. The topics covered included knowledge of female circumcision and attitudes towards the practice of circumcision. This is the first KDHS to collect information from men. Female respondents who had ever heard of female circumcision were asked additional questions, including whether they were circumcised and, if so, their age at circumcision, the type of circumcision, and the person who performed the procedure. They were also asked questions regarding the circumcision status of their daughters up to age 14.

18.1 KNOWLEDGE OF FEMALE CIRCUMCISION

Table 18.1 shows the percentage of women and men age 15-49 who have heard of female circumcision by background characteristics. Knowledge of FGC is virtually universal. Ninety-seven percent of women and 98 percent of men have heard of FGC. Similarly, in the 2008-09 KDHS, 96 percent of women had heard of FGC.

Women (95 percent) and men (94 percent) in the youngest age group (15-19) are least likely to have heard of FGC, as are women (79 percent) and men (94 percent) who do not identify with any religion. Women in the Mijikenda/Swahili ethnic group (83 percent) and women in the Coast region (90 percent) are less likely than other women to have heard of FGC. Among both women and men, knowledge of FGC generally increases with increasing education and wealth.

Table 18.1 Knowledge of female circumcision

18.2 PREVALENCE OF AND AGE AT CIRCUMCISION

Table 18.2 presents the percentage of women age 15-49 who are circumcised and the percent distribution of circumcised women by type of circumcision, according to background characteristics. In the 2014 KDHS, 21 percent of women reported being circumcised, as compared with 27 percent in 2008-09 and 32 percent in 2003. The majority of circumcised women (87 percent) had a cut with flesh removed, 9 percent reported that their genital area had been sewn closed, 2 percent were cut with no flesh removed, and 2 percent did not know or did not have a response recorded.

Table 18.2 Prevalence of female circumcision

Percentage of women 15-49 circumcised, and percent distribution of circumcised women by type of circumcision according to background characteristics, Kenya 2014

Note: Among all women, total includes three women for whom information on religion is missing and seven women for whom information on ethnic group is missing. Among circumcised women, total includes two women for whom information on religion is missing and three women for whom information on ethnic group is missing. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.

The proportion of circumcised women increases with age. Muslim women (51 percent) are more likely to have been circumcised than women from other religious groups. However, even among Protestants/other Christians, the religious group with the lowest prevalence, 18 percent of women have been circumcised. Muslim women are more likely to have had the type of circumcision in which their genital area is sewn closed (30 percent) than women from all other religious groups (4-6 percent).

The proportion of women who are circumcised varies by ethnic group (Figure 18.1), with the majority of women in the Somali (94 percent), Samburu (86 percent), Kisii (84 percent), and Maasai (78 percent) groups being circumcised. In contrast, 2 percent or less of women in the Luo, Luhya, Turkana, and Mijikenda/Swahili ethnic groups are circumcised. Rural women (26 percent) are more likely than urban women (14 percent) to be circumcised. There are large regional variations; the proportion of circumcised women ranges from 1 percent in Western to 98 percent in North Eastern.

Figure 18.1 **Percentage of women age 15-49 circumcised by ethnic group**

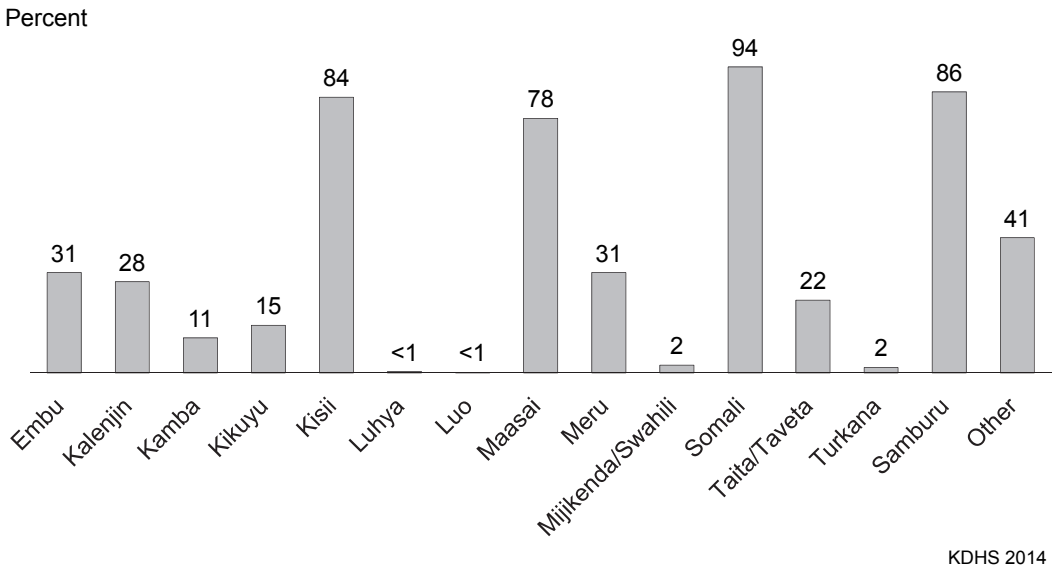

Table 18.3 shows the percent distribution of circumcised women age 15-49 by age at circumcision, according to background characteristics. It should be noted that when women are circumcised at a young age, their recollection of exactly how old they were at the time may be imperfect. A small proportion of women (2 percent) were circumcised when they were less than age 5. Twenty-seven percent were circumcised when they were age 5-9, 43 percent were circumcised when they were age 10-14, and 27 percent were circumcised at age 15 or older.

There is some evidence of a trend over time to circumcise girls at younger ages. Forty-six percent of circumcised women age 15-19 were circumcised at age 5-9, as compared with 17 percent of circumcised women age 45-49. While there is overlap in these categories, Muslim women are much more likely to be circumcised at age 5-9 (65 percent) than women from other religious groups, as are Somali women (73 percent. Urban women are more likely to be circumcised at age 5-9 (34 percent) than rural women (24 percent). About 78 percent of women in urban areas are circumcised by age 14, compared with 69 percent of those in rural areas. Women in the Coast region were most likely to have been circumcised when they were less than age 5 (22 percent).

Note: Total includes two women for whom information on religion is missing and three women for whom information on ethnic group is missing. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.
[1] Includes women who reported they were circumcised during infancy but did not provide a specific age.

Table 18.4 shows the percent distribution of girls age 0-14 by age at circumcision and the percentage of girls circumcised according to current age. Three percent of girls age 0-14 are circumcised; the likelihood of being circumcised increases with age, and 7 percent of girls age 10-14 are circumcised.

Table 18.4 Prevalence of circumcision and age at circumcision: Girls 0-14

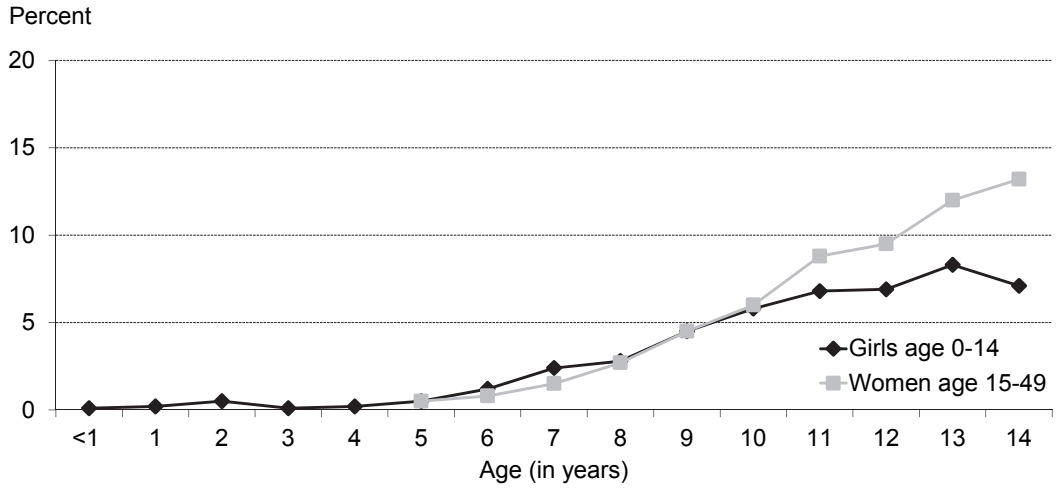
Percent distribution of girls age 0-14 by age at circumcision, and percentage of girls circumcised according to current age, Kenya 2014

Background characteristic	Age at circumcision				Percentage not circumcised	Total	Number of girls	Percentage circumcised
	<1	1-4	5-9	10-14				
Current age of girls								
0-4	0.0	0.0	na	na	99.8	100.0	4,426	0.2
5-9	0.0	0.3	1.9	na	97.8	100.0	4,453	2.2
10-14	0.0	0.2	5.0	1.7	93.1	100.0	3,508	6.9
Total	0.0	0.2	2.1	0.5	97.2	100.0	12,388	2.8

Note: The circumcision status of girls is reported by their mothers. Totals may not add up to 100 percent because girls with missing information are not shown separately.
na = Not applicable due to censoring.

A comparison of age at circumcision between girls age 0-14 and women age 15-49 is shown in Figure 18.2. A slightly higher proportion of women than girls were circumcised at each particular age. For example, girls currently age 14 are less likely to be circumcised at that age than women who are currently age 15-49.

Figure 18.2 **Percentage of women age 15-49 and girls age 0-14 circumcised by age**



Note: Data on age at circumcision for women who were circumcised before age 5 is not available in single years of age. Data for girls is based on current status. The figure shows the percentage of girls currently in each age group who have been circumcised (according to mother's report). Data for women age 15-49 is based on recall and shows the percentage who were circumcised by specific exact ages.

KDHS 2014

Table 18.5 shows the percentage of girls age 0-14 who are circumcised according to age and mother's background characteristics. Twenty percent of girls with Muslim mothers are circumcised. Thirty-six percent of girls whose mothers are Somali and 16 percent whose mothers are Kisii are circumcised, as compared with 6 percent or less among all other ethnic groups. Forty percent of girls in North Eastern are circumcised.

18.3 ASPECTS OF CIRCUMCISION AMONG CIRCUMCISED GIRLS AND WOMEN

Infibulation is the excision of exterior genitalia and the sewing shut of the opening to the vagina. It is the type of FGC most likely to result in severe, long-term medical complications. Table 18.6 presents the percent distribution of girls age 0-14 who are circumcised by whether or not they are infibulated, according to their mother's background characteristics.

Eight percent of circumcised girls are infibulated. Eighty-six percent of circumcised girls are not infibulated, and infibulation status is unknown for 6 percent of circumcised girls. Infibulation is most common among girls whose mothers are Muslim (13 percent), have no education (11 percent), or are themselves infibulated (25 percent).

Table 18.6 Infibulation among circumcised girls age 0-14

Note: The circumcision status of girls is reported by their mothers. Figures in parentheses are based on 25-49 unweighted cases. An asterisk denotes a figure based on fewer than 25 unweighted cases that has been suppressed.

Communities that practice FGC have people who specialise in performing the procedure, including traditional circumcisers, traditional birth attendants, and medical professionals. Table 18.7 shows the percent distribution of circumcised girls age 0-14 and women age 15-49 according to the person performing the circumcision and the type of circumcision. Seventy-three percent of girls and 81 percent of women were circumcised by a traditional circumciser. Younger girls (age 5-9) are more likely than older girls (age 10-14) to have been circumcised by a traditional circumciser (85 percent versus 70 percent). Among women age 15-49, there has been an increase in the proportion circumcised by a traditional circumciser since the 2008-09 KDHS (75 percent).

Table 18.7 Aspects of circumcision among circumcised girls age 0-14 and women age 15-49

18.4 RELIGIOUS AND COMMUNITY ATTITUDES TOWARDS FGC

Table 18.8 shows the percent distribution of women and men age 15-49 who have heard of female circumcision according to their opinion on whether or not their religion requires female circumcision, by background characteristics. Five percent of women and 6 percent of men believe that circumcision is required by their religion. Circumcised women are more likely (18 percent) than those who have not been circumcised to say that circumcision is required by their religion (1 percent). Muslim women (44 percent) and men (36 percent) are more likely to say that circumcision is required by their religion than members of other religious groups.

Respondents' opinions about whether circumcision is required by their religion vary according to ethnic group; the majority of Somali women (82 percent) and men (83 percent) believe that circumcision is required by their religion. Residents of North Eastern are most likely to report that circumcision is required by their religion (89 percent of women and 87 percent of men). Women (36 percent) and men (37 percent) with no education are more likely to report that circumcision is required by their religion than women and men with any education. Women (15 percent) and men (14 percent) in the lowest wealth quintile are most likely to believe that circumcision is required by their religion.

Table 18.8 Opinions of women and men about whether circumcision is required by religion

Table 18.9 shows the percent distribution of women and men age 15-49 who have heard of female circumcision according to their opinion on whether their community requires female circumcision, by background characteristics. Eight percent of women and 11 percent of men believe that circumcision is required by their community. The patterns seen above for opinions related to religion are repeated, although circumcised women are more likely to say that circumcision is required by their community (30 percent) than by their religion (18 percent). Also, men with no education are more likely to say that

circumcision is required by their community (50 percent) than by their religion (37 percent). Both women (23 percent) and men (22 percent) in the lowest wealth quintile are more likely to say that circumcision is required by their community than by their religion (15 percent and 14 percent, respectively).

Table 18.9 Opinions of women and men about whether circumcision is required by the community

18.5 SUPPORT FOR THE CONTINUATION OF FGC

Table 18.10 shows the percent distribution of women and men age 15-49 who have heard of circumcision according to their opinion on whether the practice should be continued, by background characteristics. Six percent of women and 9 percent of men believe that circumcision should continue. Among women, there has been some change since 2008-09 in the percentage who believe that the practice should continue (9 percent). The patterns seen above for respondents' opinions on whether female circumcision is required by their religion or their community are repeated. There has been a slight decrease since 2008-09 in the proportion of circumcised women who believe that the practice should continue (from 29 percent in 2008-09 to 23 percent in 2014); the proportion has also decreased among women living in Nyanza (from 17 percent to 9 percent) and Nairobi (from 6 percent to 2 percent). However, there has been a slight increase since 2008-09 in the proportion of women with no education who believe that the practice should continue (from 34 percent to 40 percent).

Table 18.10 Opinions of women and men about whether the practice of circumcision should continue

Percent distribution of women and men age 15-49 who have heard of female circumcision by opinion on whether the practice of circumcision should be continued, by background characteristics, Kenya 2014

[1] Using the number of households falling into specific response categories, the household response rate (HRR) is calculated as:

$$\frac{100 * C}{C + HP + P + R + DNF}$$

[2] The eligible men response rate (EMRR) is equivalent to the percentage of interviews completed (EMC).
[3] The overall men response rate (OMRR) is calculated as: OMRR = HRR * EMRR/100

ESTIMATES OF SAMPLING ERRORS *Appendix* B

The estimates from a sample survey are affected by two types of errors: non-sampling errors and sampling errors. Non-sampling errors are the results of mistakes made in implementing data collection and data processing, such as failure to locate and interview the correct household, misunderstanding of the questions on the part of either the interviewer or the respondent, and data entry errors. Although numerous efforts were made during the implementation of the 2014 Kenya Demographic and Health Survey (2014 KDHS) to minimise this type of error, non-sampling errors are impossible to avoid and difficult to evaluate statistically.

Sampling errors, on the other hand, can be evaluated statistically. The sample of respondents selected in the 2014 KDHS is only one of many samples that could have been selected from the same population, using the same design and expected size. Each of these samples would yield results that differ somewhat from the results of the actual sample selected. Sampling errors are a measure of the variability between all possible samples. Although the degree of variability is not known exactly, it can be estimated from the survey results.

Sampling error is usually measured in terms of the *standard error* for a particular statistic (mean, percentage, etc.), which is the square root of the variance. The standard error can be used to calculate confidence intervals within which the true value for the population can reasonably be assumed to fall. For example, for any given statistic calculated from a sample survey, the value of that statistic will fall within a range of plus or minus two times the standard error of that statistic in 95 percent of all possible samples of identical size and design.

If the sample of respondents had been selected as a simple random sample, it would have been possible to use straightforward formulas for calculating sampling errors. However, the 2014 KDHS sample is the result of a multi-stage stratified design, and, consequently, it was necessary to use more complex formulae. Sampling errors are computed in either ISSA or SAS, using programs developed by ICF Macro. These programs use the Taylor linearisation method of variance estimation for survey estimates that are means, proportions or ratios. The Jackknife repeated replication method is used for variance estimation of more complex statistics such as fertility and mortality rates.

The Taylor linearisation method treats any percentage or average as a ratio estimate, $r = y/x$, where y represents the total sample value for variable y, and x represents the total number of cases in the group or subgroup under consideration. The variance of r is computed using the formula given below, with the standard error being the square root of the variance:

$$SE^2(r) = var(r) = \frac{1-f}{x^2}\sum_{h=1}^{H}\left[\frac{m_h}{m_h-1}\left(\sum_{i=1}^{m_h} z_{hi}^2 - \frac{z_h^2}{m_h}\right)\right]$$

in which

$$z_{hi} = y_{hi} - rx_{hi} \text{ , and } z_h = y_h - rx_h$$

where h represents the stratum which varies from 1 to H,
m_h is the total number of clusters selected in the h^{th} stratum,
y_{hi} is the sum of the weighted values of variable y in the i^{th} cluster in the h^{th} stratum,
x_{hi} is the sum of the weighted number of cases in the i^{th} cluster in the h^{th} stratum, and
f is the overall sampling fraction, which is so small that it is ignored.

The Jackknife repeated replication method derives estimates of complex rates from each of several replications of the parent sample, and calculates standard errors for these estimates using simple formulae. Each replication considers *all but one* cluster in the calculation of the estimates. Pseudo-independent replications are thus created. In the 2014 KDHS, there were 1,594 non-empty clusters. Hence, 1,594 replications were created. The variance of a rate *r* is calculated as follows:

$$SE^2(r) = var(r) = \frac{1}{k(k-1)} \sum_{i=1}^{k} (r_i - r)^2$$

in which

$$r_i = kr - (k-1)r_{(i)}$$

where r is the estimate computed from the full sample of 1,594 clusters,

$r_{(i)}$ is the estimate computed from the reduced sample of 1,593 clusters (i^{th} cluster excluded), and

k is the total number of clusters.

In addition to the standard error, the design effect (DEFT) for each estimate is also calculated. The design effect is defined as the ratio between the standard error using the given sample design and the standard error that would result if a simple random sample had been used. A DEFT value of 1.0 indicates that the sample design is as efficient as a simple random sample, while a value greater than 1.0 indicates the increase in the sampling error due to the use of a more complex and less statistically efficient design. Relative standard errors and confidence limits for the estimates are also calculated.

Sampling errors for the 2014 KDHS are calculated for selected variables considered to be of primary interest. The results are presented in this appendix for the country as a whole, for urban and rural areas separately, and for each of the eight regions. For each variable, the type of statistic (mean, proportion, or rate) and the base population are given in Table B.1. Tables B.2 through B.12 present the value of the statistic (R), its standard error (SE), the number of un-weighted (N) and weighted (WN) cases, the design effect (DEFT), the relative standard error (SE/R), and the 95 percent confidence limits (R±2SE), for each variable. The sampling errors for mortality rates are presented for the five year period preceding the survey for the whole country and for the ten year period preceding the survey by residence and region. The DEFT is considered undefined when the standard error considering a simple random sample is zero (when the estimate is close to 0 or 1). In the case of the total fertility rate, the number of un-weighted cases is not relevant, as there is no known un-weighted value for woman-years of exposure to childbearing.

The confidence interval (e.g., as calculated for *children ever born to women age 40-49*) can be interpreted as follows: the overall average from the national sample is 5.036 and its standard error is 0.057. Therefore, to obtain the 95 percent confidence limits, one adds and subtracts twice the standard error to the sample estimate, i.e., 5.036±2×0.057. There is a high probability (95 percent) that the *true* average number of children ever born to all women aged 40 to 49 is between 4.923 and 5.149.

For the total sample, the value of the DEFT, averaged over all variables, is 1.568. This means that, due to multi-stage clustering of the sample, the average standard error is increased by a factor of 1.568 over that in an equivalent simple random sample.

Table B.1 List of selected variables for sampling errors, Kenya 2014

Variable	Estimate	Base population
	WOMEN	
Urban residence	Proportion	All women 15-49
Literacy	Proportion	All women 15-49
No education	Proportion	All women 15-49
Secondary or higher education	Proportion	All women 15-49
Never married/in union	Proportion	All women 15-49
Currently married/in union	Proportion	All women 15-49
Married before age 20	Proportion	All women 20-49
Had sexual intercourse before age 18	Proportion	All women 20-49
Currently pregnant	Proportion	All women 15-49
Children ever born	Mean	All women 15-49
Children surviving	Mean	All women 15-49
Children ever born to women age 40-49	Mean	All women 40-49
Know any contraceptive method	Proportion	Currently married women 15-49
Know any modern contraceptive method	Proportion	Currently married women 15-49
Currently using any method	Proportion	Currently married women 15-49
Currently using a modern method	Proportion	Currently married women 15-49
Currently using a traditional method	Proportion	Currently married women 15-49
Currently using pill	Proportion	Currently married women 15-49
Currently using IUD	Proportion	Currently married women 15-49
Currently using male condoms	Proportion	Currently married women 15-49
Currently using injectables	Proportion	Currently married women 15-49
Currently using female sterilisation	Proportion	Currently married women 15-49
Currently using implant	Proportion	Currently married women 15-49
Currently using rhythm	Proportion	Currently married women 15-49
Currently using withdrawal	Proportion	Currently married women 15-49
Used public sector source for family planning	Proportion	Current users of modern method
Want no more children	Proportion	Currently married women 15-49
Want to delay next birth at least 2 years	Proportion	Currently married women 15-49
Ideal number of children	Mean	All women 15-49
Mothers received antenatal care for last birth	Proportion	Women with a live birth in last five years
Mothers protected against tetanus for last birth	Proportion	Women with a live birth in last five years
Births with skilled attendant at delivery	Proportion	Births occurring 1-59 months before survey
Delivery in a health facility	Proportion	Births occurring 1-59 months before survey
Had diarrhoea in the past 2 weeks	Proportion	Children under 5
Treated with ORS	Proportion	Children under 5 with diarrhoea in past 2 weeks
Sought medical treatment	Proportion	Children under 5 with diarrhoea in past 2 weeks
Vaccination card seen	Proportion	Children 12-23 months
Received BCG vaccination	Proportion	Children 12-23 months
Received DPT vaccination (3 doses)	Proportion	Children 12-23 months
Received polio vaccination (3 doses)	Proportion	Children 12-23 months
Received measles vaccination	Proportion	Children 12-23 months
Fully vaccinated	Proportion	Children 12-23 months
Vitamin A supplementation in last 6 months	Proportion	Children 6-59 months
Owns at least one insecticide treated net (ITN)	Proportion	Households
Child slept under ITN last night	Proportion	Children under 5 in household
Received 2+ doses of SP/Fansidar during antenatal visit (IPTp)	Proportion	Women 15-49 with birth in last 2 years
Child has fever in last two weeks	Proportion	Children under 5 in women's birth history
Child took antimalarial	Proportion	Children under 5 in women's birth history
Height-for-age (-2SD)	Proportion	Children under 5 who are measured
Weight-for-height (-2SD)	Proportion	Children under 5 who are measured
Weight-for-age (-2SD)	Proportion	Children under 5 who are measured
Body Mass Index (BMI) <18.5	Proportion	All women 15-49 who were measured
Had 2+ sexual partners in past 12 months	Proportion	All women 15-49
Condom use at last sex	Proportion	Women 15-49 with 2+ partners in past 12 months
Abstinence among youth (never had sex)	Proportion	Never-married women 15-24
Sexually active in past 12 months among never-married youth	Proportion	Never-married women 15-24
Had an HIV test and received results in past 12 months	Proportion	All women 15-49
Accepting attitudes towards people with HIV	Proportion	All women who have heard of HIV/AIDS
Ever experienced any physical violence since age 15 by anyone	Proportion	All women 15-49
Ever experienced any sexual violence by anyone	Proportion	All women 15-49
Ever experienced physical/sexual violence by any husband/partner	Proportion	Ever-married women 15-49
Physical/sexual violence in the past 12 months by any husband/partner	Proportion	Ever-married women 15-49
Total fertility rate (3 years)	Rate	Women-years of exposure to childbearing
Neonatal mortality rate[1]	Rate	Children exposed to the risk of mortality
Post-neonatal mortality rate[1]	Rate	Children exposed to the risk of mortality
Infant mortality rate[1]	Rate	Children exposed to the risk of mortality
Child mortality rate[1]	Rate	Children exposed to the risk of mortality
Under-five mortality rate[1]	Rate	Children exposed to the risk of mortality

Table B.1—*Continued*

Variable	Estimate	Base population
	MEN	
Urban residence	Proportion	All men 15-49
Literacy	Proportion	All men 15-49
No education	Proportion	All men 15-49
Secondary or higher education	Proportion	All men 15-49
Never married/in union	Proportion	All men 15-49
Currently married/in union	Proportion	All men 15-49
Had sexual intercourse before age 18	Proportion	All men 20-49
Know any contraceptive method	Proportion	Currently married men 15-49
Know a modern method	Proportion	Currently married men 15-49
Want no more children	Proportion	Currently married men 15-49
Want to delay next birth at least 2 years	Proportion	Currently married men 15-49
Ideal number of children	Mean	All men 15-49
Had 2+ sexual partners in past 12 months	Proportion	All men 15-49
Condom use at last sex	Proportion	Men 15-49 with 2+ partners in past 12 months
Abstinence among youth (never had sex)	Proportion	Never-married men 15-24
Sexually active in past 12 months among never-married youth	Proportion	Never-married men 15-24
Paid for sexual intercourse in past 12 months	Proportion	All men 15-49
Had an HIV test and received results in past 12 months	Proportion	All men 15-49
Accepting attitudes towards people with HIV	Proportion	All men who have heard of HIV/AIDS
Ever experienced any physical violence since age 15 by anyone	Proportion	All men 15-49
Ever experienced any sexual violence by anyone	Proportion	All men 15-49
Ever experienced physical/sexual violence by any wife/partner	Proportion	Ever-married men 15-49
Physical/sexual violence in the past 12 months by any wife/partner	Proportion	Ever-married men 15-49

[1] The mortality rates are calculated for 5 years and 10 years before the survey for the national sample and regional samples, respectively.

34	844	1.2	834	1.2					
35	995	1.4	1,065	1.6					
36	794	1.1	804	1.2	Total	70,341	100.0	67,439	100.0
37	671	1.0	585	0.9					

Note: The de facto population includes all residents and nonresidents who stayed in the household the night before the interview.

Table C.2.1 Age distribution of eligible and interviewed women

De facto household population of women age 10-54 and interviewed women age 15-49; and percent distribution and percentage of eligible women who were interviewed (weighted), by five-year age groups, Kenya 2014

Age group	Household population of women age 10-54	Interviewed women age 15-49		Percentage of eligible women interviewed
		Number	Percentage	
10-14	9,376	na	na	na
15-19	6,118	5,776	18.6	94.4
20-24	6,027	5,757	18.6	95.5
25-29	6,293	6,073	19.6	96.5
30-34	4,699	4,529	14.6	96.4
35-39	3,888	3,769	12.2	96.9
40-44	2,950	2,878	9.3	97.6
45-49	2,272	2,202	7.1	96.9
50-54	2,400	na	na	na
15-49	32,247	30,984	100.0	96.1

Note: The de facto population includes all residents and nonresidents who stayed in the household the night before the interview. Weights for both household population of women and interviewed women are household weights. Age is based on the Household Questionnaire.
na = Not applicable

Table C.2.2 Age distribution of eligible and interviewed men

De facto household population of men age 10-64 and interviewed men age 15-59; and percent distribution and percentage of eligible men who were interviewed (weighted), by five-year age groups, Kenya 2014

Age group	Household population of men age 10-59	Interviewed men age 15-54		Percentage of eligible men interviewed
		Number	Percentage	
10-14	4,600	na	na	na
15-19	2,849	2,628	20.1	92.2
20-24	2,330	2,122	16.2	91.1
25-29	2,452	2,184	16.7	89.1
30-34	2,123	1,829	14.0	86.2
35-39	1,688	1,457	11.1	86.3
40-44	1,423	1,253	9.6	88.0
45-49	953	845	6.5	88.7
50-54	864	771	5.9	89.2
55-59	720	na	na	na
60-64	630	na	na	na
15-59	15,402	13,089	100.0	85.0

Note: The de facto population includes all residents and nonresidents who stayed in the household the night before the interview. Weights for both household population of men and interviewed men are household weights. Age is based on the Household Questionnaire.
na = Not applicable

Table C.3 Completeness of reporting

Percentage of observations missing information for selected demographic and health questions (weighted), Kenya 2014

Subject		Percentage with information missing	Number of cases
Birth date	Births in the 15 years preceding the survey		
Month only		0.90	55,412
Month and year		0.04	55,412
Age at death	Deceased children born in the 15 years preceding the survey	0.00	3,353
Age/date at first union[1]	Ever married women age 15-49	0.26	22,082
	Ever married men age 15-54	0.26	7,457
Respondent's education	All women age 15-49	0.00	31,079
	All men age 15-54	0.00	12,819
Diarrhoea in past 2 weeks	Living children 0-59 months	0.99	18,702
Anthropometry of children	Living children age 0-59 months (from the Household Questionnaire)		
Height		2.47	19,790
Weight		2.25	19,790
Height or weight		2.51	19,790
Anthropometry of women	Women age 15-49 (from the Household Questionnaire)		
Height		5.67	15,260
Weight		5.50	15,260
Height or weight		5.68	15,260

[1] Both year and age missing

Table C.4 Births by calendar years

Number of births, percentage with complete birth date, sex ratio at birth, and calendar year ratio by calendar year, according to living, dead, and total children (weighted), Kenya 2014

	Number of births			Percentage with complete birth date[1]			Sex ratio at birth[2]			Calendar year ratio[3]		
Calendar year	Living	Dead	Total	Living	Dead	Total	Living	Dead	Total	Living	Dead	Total

Note: Table is based on children who slept in the household the night before the interview. Each of the indices is expressed in standard deviation units (SD) from the median of the NCHS/CDC/WHO International Reference Population. Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight.

[1] Recumbent length is measured for children under age 2, or in the few cases when the age of the child is unknown and the child is less than 85cm; standing height is measured for all other children to be consistent with Table 11.1.1

[2] Includes children who are below -3 standard deviations (SD) from the International Reference Population median

[3] Excludes children whose mothers were not interviewed

[4] First-born twins (triplets, etc.) are counted as first births because they do not have a previous birth interval.

[5] Includes children whose mothers are deceased

[6] Excludes children whose mothers were not interviewed, children whose mothers were not weighed and measured, and children whose mothers are pregnant or gave birth within the preceding 2 months. Mother's nutritional status in terms of BMI (Body Mass Index) is presented in Table 11.10.1

[7] For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire.

Table C.8 Completeness of information on siblings

Completeness of data on survival status of sisters and brothers reported by interviewed women, age of living siblings and age at death (AD) and years since death (YSD) of dead siblings (unweighted), Kenya 2014

	Sisters		Brothers		All siblings	
	Number	Percent	Number	Percent	Number	Percent
All siblings	42,006	100.0	42,607	100.0	84,613	100.0
Living	37,414	89.1	37,292	87.5	74,706	88.3
Dead	4,577	10.9	5,291	12.4	9,868	11.7
Survival status unknown	15	0.0	24	0.1	39	0.0
Living siblings	37,414	100.0	37,292	100.0	74,706	100.0
Age reported	37,253	99.6	37,148	99.6	74,401	99.6
Age missing	161	0.4	144	0.4	305	0.4
Dead siblings	4,577	100.0	5,291	100.0	9,868	100.0
AD and YSD reported	4,509	98.5	5,174	97.8	9,683	98.1
Missing only AD	29	0.6	45	0.9	74	0.7
Missing only YSD	16	0.3	25	0.5	41	0.4
Missing AD and YSD	23	0.5	47	0.9	70	0.7

Table C.9 Sibship size and sex ratio of siblings

Mean sibship size and sex ratio of siblings at birth, Kenya 2014

Age of respondents	Mean sibship size[1]	Sex ratio of siblings at birth[2]
15-19	5.8	98.8
20-24	6.1	95.7
25-29	6.5	101.4
30-34	6.9	102.9
35-39	7.3	103.3
40-44	7.7	98.5
45-49	7.8	101.4
Total	6.7	100.2

[1] Includes the respondent
[2] Excludes the respondent

QUESTIONNAIRES

Appendix E

OVERVIEW OF DATA COLLECTED IN FULL AND SHORT QUESTIONNAIRES

Household Questionnaire

	Full	Short
Composition (e.g., headship, size, age, sex, education)	•	•
Characteristics (e.g., source of water, type of sanitation facilities; exposure to second-hand smoke inside the home)	•	•
Wealth index	•	•
Household ownership and use of mosquito nets	•	•
Household ownership of dwelling, land	•	
Household receipt of social assistance	•	
Nutritional status of women age 15-49 years[1]	•	
Nutritional status of children under age five years	•	•

Woman's Questionnaire

	Full	Short
Individual characteristics (e.g., age, sex, education, marital status, media exposure)	•	•
Fertility and reproductive history	•	•
Knowledge and use of family planning methods	•	•
Fertility preferences	•	
Antenatal and delivery care	•	•
Breastfeeding	•	
Vaccinations and childhood illnesses	•	•
Infant and child feeding practices	•	
Childhood mortality	•	•
Marriage and sexual activity	•	•
Woman's work and husband's background characteristics	•	
Awareness and behaviour about HIV and other sexually transmitted infections	•	•
Adult and maternal mortality	•	
Domestic violence	•	
Female circumcision	•	
Fistula	•	

[1] Women's nutritional status, calculated from anthropometry measurements, is an exception to the 2014 KDHS recommendations for estimation of indicators at the county level. Although anthropometry data were not collected from women in the one-half of households administered the short questionnaire, there are sufficient cases from the one-half of households administered the full questionnaire to calculate county level estimates of women's nutritional status.

INTRODUCTION AND CONSENT

Hello. My name is _____. I am working with the Kenya National Bureau of Statistics. We are conducting a survey about health all over Kenya. The information we collect will help the government to plan health services. Your household was selected for the survey. I would like to ask you some questions about your household. The questions usually take about 30 to 60 minutes. All of the answers you give will be confidential and will not be shared with anyone other than members of our survey team. You don't have to be in the survey, but we hope you will agree to answer the questions since your views are important. If I ask you any question you don't want to answer, just let me know and I will go on to the next question or you can stop the interview at any time. In case you need more information about the survey, you may contact the person listed on this card.

GIVE CARD WITH CONTACT INFORMATION

Do you have any questions?
May I begin the interview now?

TABLE FOR SELECTION OF WOMEN FOR SECTION 14: DOMESTIC VIOLENCE QUESTIONS

101A ONLY ONE INDIVIDUAL (ONE WOMAN OR ONE MAN) SHOULD BE SELECTED FOR DOMESTIC VIOLENCE QUESTIONS

CHECK COVER PAGE:
HOUSEHOLD SELECTED FOR WOMEN'S SECTION 14?

YES ☐ → USE THE TABLE BELOW TO SELECT ONE WOMAN FROM THIS HH TO BE INTERVIEWED WITH THE DV QUESTIONS

NO ☐ → GO TO 101B

HOW TO USE THE TABLE FOR SELECTION OF A RESPONDENT

LAST DIGIT OF QUESTIONANIRE SERIAL NUMBER (GO TO THIS ROW NUMBER) ☐

TOTAL NUMBER OF ELIGIBLE WOMEN (COL 9) (GO TO THIS COLUMN NUMBER) ☐
IF ZERO → GO TO 102

LOOK AT THE LAST DIGIT OF THE HOUSEHOLD QUESTIONNAIRE SERIAL NUMBER ON THE COVER PAGE. THIS IS THE ROW NUMBER YOU SHOULD GO TO. CHECK THE TOTAL NUMBER OF ELIGIBLE WOMEN (COLUMN 9) IN THE HOUSEHOLD SCHEDULE. THIS IS THE COLUMN NUMBER YOU SHOULD GO TO. FOLLOW THE SELECTED ROW AND COLUMN TO THE CELL WHERE THEY MEET AND CIRCLE THE NUMBER IN THE CELL. THIS IS THE NUMBER OF THE WOMAN SELECTED FOR THE DOMESTIC VIOLENCE QUESTIONS FROM THE LIST OF ELIGIBLE WOMEN IN COLUMN 9 OF THE HOUSEHOLD SCHEDULE. WRITE THE NAME AND LINE NUMBER OF THE SELECTED WOMAN IN THE SPACE BELOW THE TABLE.

EXAMPLE: THE HOUSEHOLD QUESTIONNAIRE SERIAL NUMBER IS '716' AND THE HOUSEHOLD SCHEDULE COLUMN 9 SHOWS THAT THERE ARE THREE ELIGIBLE WOMEN AGE 15-49 IN THE HOUSEHOLD (LINE NUMBERS 02, 04, AND 05). SINCE THE LAST DIGIT OF THE HOUSEHOLD SERIAL NUMBER IS '6' GO TO ROW '6' AND SINCE THERE ARE THREE ELIGIBLE WOMEN IN THE HOUSEHOLD, GO TO COLUMN '3'. FOLLOW THE ROW AND COLUMN AND FIND THE NUMBER IN THE CELL WHERE THEY MEET ('2') AND CIRCLE THE NUMBER. NOW GO TO THE HOUSEHOLD SCHEDULE AND FIND THE SECOND WOMAN WHO IS ELIGIBLE FOR THE WOMAN'S INTERVIEW (LINE NUMBER '04' IN THIS EXAMPLE). WRITE HER NAME AND LINE NUMBER IN THE SPACE BELOW THE TABLE.

LAST DIGIT OF THE HOUSEHOLD QUESTIONNAIRE SERIAL NUMBER	TOTAL NUMBER OF ELIGIBLE WOMEN AGE 15-49 IN HOUSEHOLD SCHEDULE COLUMN 9							
	1	2	3	4	5	6	7	8
0	1	2	2	4	3	6	5	4
1	1	1	3	1	4	1	6	5

INTRODUCTION AND CONSENT

Hello. My name is _____. I am working with the Kenya National Bureau of Statistics. We are conducting a survey about health all over Kenya. The information we collect will help the government to plan health services. Your household was selected for the survey. I would like to ask you some questions about your household. The questions usually take about 30 to 60 minutes. All of the answers you give will be confidential and will not be shared with anyone other than members of our survey team. You don't have to be in the survey, but we hope you will agree to answer the questions since your views are important. If I ask you any question you don't want to answer, just let me know and I will go on to the next question or you can stop the interview at any time. In case you need more information about the survey, you may contact the person listed on this card.

GIVE CARD WITH CONTACT INFORMATION

Do you have any questions?
May I begin the interview now?

SECTION 1. RESPONDENT'S BACKGROUND

INTRODUCTION AND CONSENT

INFORMED CONSENT

Hello. My name is _____. I am working with the Kenya National Bureau of Statistics. We are conducting a survey about health all over Kenya. The information we collect will help the government to plan health services. Your household was selected for the survey. The questions usually take about 30 to 60 minutes. All of the answers you give will be confidential and will not be shared with anyone other than members of our survey team. You don't have to be in the survey, but we hope you will agree to answer the questions since your views are important. If I ask you any question you don't want to answer, just let me know and I will go on to the next question or you can stop the interview at any time.

In case you need more information about the survey, you may contact the person listed on the card that has already been given to your household.
Do you have any questions? May I begin the interview now?

SIGNATURE OF INTERVIEWER: _____ DATE: _____

RESPONDENT AGREES TO BE INTERVIEWED . . . . . 1 ↓ RESPONDENT DOES NOT AGREE TO BE INTERVIEWED . . . 2 → END

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP
101	RECORD THE TIME.	HOUR . . . . . ☐☐ MINUTES . . . . . ☐☐	
101A	First I would like to ask some questions about you and your household. For most of the time until you were 12 years old, did you live in Nairobi, Mombasa, Kisumu, in a town, in the countryside, or outside of Kenya?	NAIROBI/ MOMBASA/ KISUMU . . . . . 1 TOWN . . . . . 2 COUNTRYSIDE . . . . . 3 OUTSIDE KENYA 4	
101B	How long have you been living continuously in (NAME OF CURRENT PLACE OF RESIDENCE)? IF LESS THAN ONE YEAR, RECORD '00' YEARS	YEARS ☐☐ ALWAYS . . . . . 95 VISITOR 96	→ 101D
101C	Just before you moved here, did you live in Nairobi, Mombasa, Kisumu, in a town, in the countryside, or outside of Kenya?	NAIROBI/ MOMBASA/ KISUMU . . . . . 1 TOWN . . . . . 2 COUNTRYSIDE . . . . . 3 OUTSIDE OF KENYA 4	
101D	What is your nationality?	KENYAN . . . . . 01 TANZANIAN . . . . . 02 UGANDAN . . . . . 03 SOMALI . . . . . 04 ETHIOPIAN . . . . . 05 SUDANESE . . . . . 06 OTHER _____ 96 (SPECIFY)	→ 102

SECTION 14: DOMESTIC VIOLENCE

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP
1401	CHECK COVER PAGE: IS WOMAN SELECTED FOR SECTION 14? WOMAN SELECTED FOR THIS SECTION ☐ ↓ WOMAN NOT SELECTED ☐ →		1433
1401A	CHECK FOR PRESENCE OF OTHERS: DO NOT CONTINUE UNTIL PRIVACY IS ENSURED. PRIVACY OBTAINED . . . . . 1 ↓ PRIVACY NOT POSSIBLE . . . . . 2 →		1432
	READ TO THE RESPONDENT Now I would like to ask you questions about some other important aspects of a woman's life. You may find some of these questions very personal. However, your answers are crucial for helping to understand the condition of women in Kenya. Let me assure you that your answers are completely confidential and will not be told to anyone and no one else in your household will know that you were asked these questions.		
1402	CHECK 601 AND 602: CURRENTLY MARRIED/ LIVING WITH A MAN ☐ ↓ FORMERLY MARRIED/ LIVED WITH A MAN (READ IN PAST TENSE AND USE 'LAST' WITH HUSBAND/PARTNER') ☐ ↓ NEVER MARRIED/ NEVER LIVED WITH A MAN ☐ →		1416
1403	First, I am going to ask you about some situations which happen to some women. Please tell me if these apply to your relationship with your (last) (husband/partner)?		
	a) He (is/was) jealous or angry if you (talk/talked) to other men?	a) JEALOUS . . . . . YES 1 NO 2 DK 8	
	b) He frequently (accuses/accused) you of being unfaithful?	b) ACCUSES . . . . . YES 1 NO 2 DK 8	
	c) He (does/did) not permit you to meet your female friends?	c) NOT MEET FRIENDS . YES 1 NO 2 DK 8	
	d) He (tries/tried) to limit your contact with your family?	d) NO FAMILY . . . . . YES 1 NO 2 DK 8	
	e) He (insists/insisted) on knowing where you (are/were) at all times?	e) WHERE YOU ARE . YES 1 NO 2 DK 8	
1404	Now I need to ask some more questions about your relationship with your (last) (husband/partner).		
	A Did your (last) (husband/partner) ever:	**B** How often did this happen during the last 12 months: often, only sometimes, or not at all?	
	a) say or do something to humiliate you in front of others?	a) EVER: YES 1 → / NO 2 ↓ — OFTEN 1 — SOMETIMES 2 — NOT IN LAST 12 MONTHS 3	
	b) threaten to hurt or harm you or someone you care about?	b) EVER: YES 1 → / NO 2 ↓ — OFTEN 1 — SOMETIMES 2 — NOT IN LAST 12 MONTHS 3	
	c) insult you or make you feel bad about yourself?	c) EVER: YES 1 → / NO 2 ↓ — OFTEN 1 — SOMETIMES 2 — NOT IN LAST 12 MONTHS 3	

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP
1405	A Did your (last) (husband/partner) ever do any of the following things to you:	B How often did this happen during the last 12 months: often, only sometimes, or not at all?	

	EVER		OFTEN	SOME-TIMES	NOT IN LAST 12 MONTHS
a) push you, shake you, or throw something at you?	a) YES	1 →	1	2	3
	NO	2 ↓

SECTION 1. RESPONDENT'S BACKGROUND

INTRODUCTION AND CONSENT

INFORMED CONSENT

Hello. My name is _____. I am working with the Kenya National Bureau of Statistics. We are conducting a survey about health all over Kenya. The information we collect will help the government to plan health services. Your household was selected for the survey. The questions usually take about 30 to 60 minutes. All of the answers you give will be confidential and will not be shared with anyone other than members of our survey team. You don't have to be in the survey, but we hope you will agree to answer the questions since your views are important. If I ask you any question you don't want to answer, just let me know and I will go on to the next question or you can stop the interview at any time.

In case you need more information about the survey, you may contact the person listed on the card that has already been given to your household.
Do you have any questions? May I begin the interview now?

SIGNATURE OF INTERVIEWER: _____ DATE: _____

RESPONDENT AGREES TO BE INTERVIEWED . . . . . 1 ↓ RESPONDENT DOES NOT AGREE TO BE INTERVIEWED . . . 2 → END

SECTION 1. RESPONDENT'S BACKGROUND

INTRODUCTION AND CONSENT

INFORMED CONSENT

Hello. My name is _____. I am working with the Kenya National Bureau of Statistics. We are conducting a survey about health all over Kenya. The information we collect will help the government to plan health services. Your household was selected for the survey. The questions usually take about 20 minutes. All of the answers you give will be confidential and will not be shared with anyone other than members of our survey team. You don't have to be in the survey, but we hope you will agree to answer the questions since your views are important. If I ask you any question you don't want to answer, just let me know and I will go on to the next question or you can stop the interview at any time.

In case you need more information about the survey, you may contact the person listed on the card that has already been given to your household.
Do you have any questions?
May I begin the interview now?

SIGNATURE OF INTERVIEWER: _____ DATE: _____
