Replication readme for "Long-Term Care Insurance and the Family"
Corina Mommaerts
2024

1. Download the necessary Health and Retirement Study data files, including RAND files as well as raw HRS files. All data are publicly available from the Health and Retirement Study upon registration: https://hrsdata.isr.umich.edu/data-products. These data are produced and distributed by the University of Michigan with funding from the National Institute on Aging (grant number NIA U01AG009740). To register for an account that enables data download, see: https://hrsdata.isr.umich.edu/user/register.
2. Run "_master.do" in Stata, converting data products to .dta files and defining directories as needed. This do-file calls other do-files to merge and clean the raw HRS data files, create analysis samples, run summary tables and motivating figures, and calculate model inputs.
3. Upload the model inputs constructed in the previous step into wherever you will be running the model Fortan code.
4. Run the Fortran code, modifying the makefile as appropriate for your computing configuration and the Fortran files for the particular exercise you wish to run. The code will output various simulation files for analysis in an "output" folder.
5. Run "_master_simulations.do" in Stata to run analyses using the model-generated simulation data, making sure to run the counterfactuals you want to analyze ahead of time. This do-file outputs all of the model-based tables and figures in the manuscript.
